with in all its crudity of construction, is a wooden-framed wheelbarrow in which the construction has been changed so the bed of the barrow is raised till it is 20 inches above the floor. The bed is also turned, so the ends of the barrow are forward and back instead of to the sides. The wheel is set so as to be under the barrow, the front of the wheel being in line with the end of the tray—not much farther forward, as in most wheelbarrows. The legs are 22 inches apart at the bottom. The handles are short—36 inches in all, from hub of wheel, and 26 inches apart at the hand holds.

It will be understood that this barrow, when loaded, is top heavy and one needs to exercise care in loading and handling it. It is well in loading to lay large pieces across the front of the scoop, thus preventing fine stuff from falling off onto the track. One needs a clear track over which to run the barrow, as it dumps so easily that a piece of rock on the track the size of a hen's egg will overturn it. But it is a great convenience. One easily runs the dirt out from the face, piling it up along the track to a depth of 18 inches to 2 feet. The best way to unload the barrow is to give it a quick forward thrust instead of dumping. At one stormy period in the winter time, when it was not practicable to attempt to hoist in the exposed place where the shaft was situated, work progressed for weeks with this contrivance where otherwise it would have been necessary to suspend operations. At another time, when the face was in exceptionally hard rock, the miner worked on for six weeks before needing assistance to hoist. Then what was broken was taken out with a whip in two and a half days. If it had been necessary to have a man and horse on the surface every day or so, say once a week, the expense would have been greatly increased. The level was fitted with track for the truck carrying the buckets used by the whip, and was thus also ready for a car when developments warrant, a temporary plankway being put down between the rails on which to run the wheelbarrow. This plankway facilitates shoveling and the material of which it is composed may be easily moved when chutes are put in and buckets or car can be loaded direct from them.

Gold Dredging in California.

NUMBER II.

The continuous-chain bucket dredger is practically the only type that is in successful operation in the gravels of the Sacramento Valley districts, New Zealand, Montana, Idaho, Colorado and Oregon, and it holds the field in gravel where there is an excess of water and where conditions are generally favorable for dredging. There are many differences in detail in the different dredgers, but under favorable conditions, such as exist in the Sacramento Valley district, in New Zealand, in the States named and in Alaska, the results obtained from these dredgers do not differ much except where the conditions are abnormal and difficult. The dredger in use is much like the ordinary continuous-chain bucket dredger used for other work, so far as the digging part goes, except that the size of shaftings and strength and weight of all parts are greatly increased. For gold mining it consists of a hull, a digger, screen, sluice-table and sluice-boxes, a stacker, a pump, amalgamator, and sometimes a sand-pump, with lines or lines and spuds to hold the boat in position and separate motors for each part where power is required.

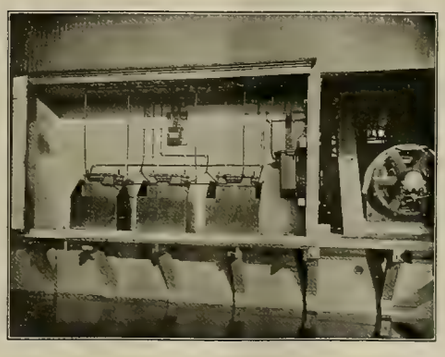
A Completed Dredger.



The Transformer on a Modern Dredger.

HULL.—So far, in California, all the hulls are made of wood, but some dredgers sent to Dutch Guiana have been built with steel hulls. This hull is rectangular in shape, with a slightly reduced width in the bow of the boat. As, practically speaking, all the parts of the machinery of a dredger are renewed during the life of a dredger, it has been suggested that steel hulls would give a longer life and more solidity; but so far none have been constructed, and probably will not be until there is a nearer approach to perfection of the machinery and a better knowledge is had of the limits of the capacity of the dredgers, for the tendency is to discard the smaller dredgers and to build those of larger capacity. To allow the digging ladder and its chain of buckets to descend to the bottom of the ground to be worked, the hull in the forward part is divided by an opening called the well, in which the ladder is moved up and down. The dimensions of the hull vary with the size of the buckets. The hulls vary in width from 30 to 40 feet, in length from 80 to 120 feet, and in depth from 7 to 9 feet.

GAUNTRIES.—Near the center of the hull there is a main gauntry, to support the upper end of the digging ladder and the main drive of the bucket chain. These have commonly been made of wood, but lately some have been constructed of steel plates. There is a stern gauntry to support the tail sluices, the conveyor ladder and the spuds, if they are used.

DIGGER.—This consists of a ladder frame, built strongly of iron or steel so that a chain of buckets may travel continuously around its length. On the best of these, manganese steel is used in the lips and bushings of the bucket, and on the ladder rollers. It has been found that a large saving in cost of repairs, which is the main cost, and where future saving can be made in the cost of dredging, is in strengthening the wearing parts of these buckets and links. A reference to the tables of cost will show how large is the proportion of the cost of working caused by the breaking of the buckets and other parts of the digger. However, this has been very much reduced since the first successful work was done at Oroville, and is being continually reduced as new dredgers are constructed. The greatest improvements are now being made by the use of special steels and in the shape of the buckets.

The bucket line is either what is called of a "close connection" or of an "open connection;" that is, the buckets follow each other on each link of the chain, or there are open links between the buckets.

Wherever there are no large bowlders and the gravel is comparatively loose, there can be no question that the close-connected buckets, with less speed, will dig more ground than will the open-connected. As to the difference between the open and the close-connected bucket in hard ground, the question as to the greatest capacity has not been settled, but it is probable that the close-connected bucket will give more satisfactory results. However, where there are large bowlders, the open-connection must be used, or the backs of the buckets will be jammed and broken. The close-connected buckets are run at a lower rate of chain speed than the open-connected buckets, the former moving at the rate of about 50 feet, or 18 to 25 buckets per minute, and the latter at 60 feet, or 12 to 15 buckets per minute. Yet in hard ground the open-connected buckets are filled to their full capacity more often than the close-connected buckets. In this connection it may be said that most of the newer dredgers at Oroville and Folsom are equipped with close-connected buckets.

Owing to the greater weight of the close-connected chain of buckets and the greater yardage handled, more power is required than for open-connected buckets. The following tables will give an idea of the difference:

The different motors in the Oroville Gold Dredging and Exploration Co.'s 5-foot Risdon dredger are of the following capacities:

	Horse Power.
Main drive	50
Stacker and screens	20
Side lines and head lines	10
Ladder hoist	15
Water pump	40
Primer pump	3
Total	138

The average amount of horse-power used in the dredger was 90. No returns were made of the proportion of the full capacity of each motor used.

The following figures are given by the builders of the Bucyrus close-connected, belt conveyor, shaking screen dredgers, as to the horse-power of the motors as built:

DREDGER WITH 3 CU FT. BUCKETS.

	Horse Power.
Digging motor	50
Winch motor	15
Screen and conveyors	20
Water pump	30
Sand pump	30
Priming pump	3
Total	148

Actual consumption, about 100 H. P.

DREDGER WITH 5 CU. FT. BUCKETS.

Digging motor	75 or 100
Winch motor	20
Screen	15
Conveyor	10 or 15
Water pump	50
Sand pump	30
Priming and clean-up	5
Total	235

Actual consumption, about 125 to 150 H. P.

DREDGER WITH 6 CU. FT. BUCKETS.

Digging motor	100
Winch motor	30
Screen	15
Stacker	15
Water	50
Sand pump	50
Priming and clean-up	7½
Total	267½

Actual consumption, not yet known.

The following data have been given as to the actual consumption of power, as per report in L. J. Hohl's paper read before the California Miners' Association:

For a 3 cu. ft. close-connected bucket dredger, with shaking screen and belt conveyor:	Horse Power.
Main drive	26 to 45
Stacker and screen	12 to 16
Water pump	45 to 50
Winches, maximum	28
Sand pump	32 to 50
For a 5 cu. ft. dredger of the same type:	
Main drive	42 to 70
Stacker and screen	10 to 20
Water pump	50 to 75
Winches, maximum	27
Sand pump, not tested.	
For a 5 cu. ft open-connected bucket dredger, with revolving screen and bucket conveyor:	
Main drive	60
Water pump	52
Screen and stacker	18½
Other motors, not tested.	

Yuba dredger, 6 cu. ft. buckets, close-connected, with shaking screen and belt conveyor. This dredger digs 60 feet deep:

Main drive	108
Water pump	68
Sand pump	63
Stacker	9
Shaking screen	11
Auxiliary supply	13

(TO BE CONTINUED.)

Placer Mining in Alaska.

NUMBER III.

SELF-DUMPING CARRIERS.—The conditions in the Klondike district appear to have necessitated the adoption of this expensive method of placer mining. Outside the Klondike field the method was not seen except at one place on Mastodon creek, in Birch Creek district. The method is adopted to work rich gravels where conditions do not permit working by ordinary shallow open cut methods, and where drifting is impossible or inadvisable.

The average depth of eight Klondike operations was 17.5 feet, being greater than that economically advisable (namely, 15 feet) for open-cut operations in general. The operator adopts this method because there are thawed streaks and channels in his deposit If such ground is drifted, the chances are that he will increase his expense to a prohibitive amount through excessive timbering and through pumping of seepage water, whereas by the open cut method the water is handled by drain. As $2.14 was the average cost of the above mentioned eight operations in the Klondike, seven drifting operations in similar deposits, with an average depth of 25.3 feet, gave an average cost of $1.95 per cubic yard, the depth of the pay or thickness of gravel actually sent to the sluice being almost exactly the same in both cases, and the capacity in the drifting being only 17.5 cubic yards less in twenty-four hours. Granting, however, that in a given deposit carrying $3 to the cubic yard of pay, the depth being 16 feet, drifting is impossible, and the rich pay, 75 feet in width, must be worked by open cut. Whatever method be adopted the moss must first be plowed up and about 6 feet of muck ground-sluiced off at a cost of 17 cents per cubic yard. Next 6 feet of barren gravel or sand must be removed, either by horse scrapers at 60 cents per cubic yard, or, if the plant warrants the operations, by steam scraper at 49 cents per cubic yard. The 4 feet of pay being laid bare, what method shall be adopted to get it into the sluice? On account of the necessarily short life of the operations, a plant whose first cost exceeds $5000 is out of the question. The greatest expense will then result from the hand shoveling in the pit The getting of the material into the receptacle in which it is conveyed to the sluice is the principal item of expense in the operation. It is therefore necessary that the high-priced shovelers get as much gravel into the wheelbarrows or buckets as possible. The bucket, 37 inches square on top, 35 inches square on bottom, and 25 inches deep, holding ¾ cubic yard, is dropped into a crib built in the bottom of the pit, to which the shovelers wheel their dirt in wheelbarrows. From four to six wheelbarrows are necessary to fill the bucket. There is no mobility to the bucket; it must always rise and fall to the same spot. Men instead of occupying all their time in shoveling are employed nearly half of it in wheeling and dumping. Five operations are necessary to get the gravel from the bank to the sluice, namely, (1) shoveling into wheelbarrows, (2) wheeling to bucket, (3) dumping to bucket, (4) raising bucket to carrier, (5) conveying and dumping to sluice.

This may now be compared with the derricking system. On Pedro creek, Fairbanks district, an open cut 15 feet of depth with 9 feet of pay gravel is worked by derricking. The plant has a capacity of 233 cubic yards a day, which is handled at a cost of $1.75 per cubic yard. The plant costs no more than the average price of a self-dumping carrier plant of daily capacity not exceeding 200 yards. The first cost of all, including a 30 H. P. boiler, was said to be $4500. Here the gravel is shoveled into buckets holding 8 cubic feet. These buckets are trammed on small trucks running on wooden tracks, hooked onto by the derrick cable and lifted and conveyed at same time to the sluice. The derrick boom has a radius of reach of 40 feet, and a much smaller proportion of time is consumed by the shovelers in tramming than when the fixed bucket on cable is used. The expense was increased in this plant by the necessity of continually thawing with twenty-four points.

As against the five operations of the cable tram system, there are only three in the derricking system if properly handled. The proof that the derricking system is superior to the wheeling and cable tram system is evident from the comparative cost. The services of a man at the dump box are generally necessary in all cases under the present sluicing practice, so that the self-dumping arrangement of the bucket helps but little.

It should be noted that the Fairbanks operator was working under higher prices generally than the Klondike miners, both for labor (at $10 a day, as against $7.50 a day) and for general supplies, and he also had an excessive amount of steam thawing. His lower cost depended primarily on his increased capacity, resulting for the most part from the increased duty of each shoveler, owing to the expeditions and adaptable system of hoisting and conveying afforded by the derrick. A derricking system in use on Seward Peninsula will be separately described.

The conclusion is that while the cable tram system, using the Dawson carrier, is excellent for drifting work, it is not to be recommended for open cut work where it is possible to obtain space for installing a derrick.

DERRICKING.—The plant described below is located on Ophir creek, in the Council mining district of Seward peninsula. The stream has been turned aside and work is proceeding in the old bed. The distinctive feature of the plant is the use of derricks in overcoming exceptional difficulties encountered in the character of the deposit. Hand labor is used in excavation, while transport of material to be washed and disposal of tailings are accomplished by derricks.

The pit in which work is being done depends for its shape and size upon the method of working and length of the derrick boom. An area of 30 feet beyond the end of the derrick boom is worked. A pit, roughly circular, having a diameter of 140 feet, is the result, since the boom reaches approximately 40 feet in its sweep, and the buckets are hauled 30 feet from the bank. Under a stratum of sand and soil, varying from 4 to 5 feet in thickness, the gravel, in places considerably mixed with sand and clay, descends to bedrock, usually 30 feet below the surface. The gravel is entirely unfrozen, rounded, and for the most part small, not over 10% exceeding 6 inches in diameter, while no bowlders are found above 18 inches. Bedrock is a massive limestone, extremely irregular in its position, and causes the greatest difficulty in the extraction of much of the gold, though this same feature must have played an important part in the enrichment of the claim. In places deep holes have been made by action of water, and the depth to which work is carried in the recovery of the gold depends entirely upon the economy with which it is extracted. There is no doubt that much gold remains below, to obtain which would not be profitable under present conditions.

Excavation is accomplished entirely by pick, the gravel being shoveled into the derrick buckets. These buckets are hauled by the derrick line, guided by hand, upon wooden skids, to a point directly beneath the end of the boom, where they are hoisted and carried to the dump box.

The buckets are of 11 cubic feet capacity and warrant detailed description. They are made of crude oil drums or gasoline tanks, cut to a height of 2 feet 8 inches, and are 2 feet 5 inches across the top. Two lugs to hold the bale are set opposite each other one-fourth distance up from the bottom. The bale is made from the original hoops of the drum. The bottom edge is strengthened by the original flange of the tank, while on the upper edge has been riveted the flange originally at the top of the tank. The bale is supplied with a catch which, when the bucket is traveling, rests in a notch constructed on its edge, which holds the bucket in an upright position. On reaching the dump box, a man on the platform with his shovel frees the catch, and the bucket dumps in turning bottom upward. In fitting the lugs holding the bale, a piece of iron 9 inches square is riveted to the inside of the material composing the drum, which is ⅛ inch thick. To the outside of the drum a strip 9 inches long, 2½ inches wide and ½ inch thick is also riveted, and to this the lug (2 inches long) is welded, making a very strong construction. These buckets weigh 140 pounds, and, including labor, blacksmith fuel and original price of drum, cost about $25.

The skids upon which the buckets are hauled are ordinary smoothed timbers, and are not fastened down. This admits of rapid change in accommodating the hauls to the advancing work. It is desirable to have these timbers as much as possible in a radius of the circle described by the derrick, as this gives a straight haul on the boom.

The derrick in use at this plant is of a very simple and practical design, there being but one haulage line, which with gravity utilized in the lean of the derrick accomplishes the desired work. The derrick leans toward the pit in which excavation is taking place—i. e., when at rest the boom swings away from the hoisting engine. (See Fig. 6.) The hauling line passes through a block at the foot of the mast and a few feet in front of it, or toward the direction of haul. In this position immediately upon receiving a hauling strain the boom tends to move toward the dump box, and once there, having disposed of its load, returns by gravity to the pit. To the end of the boom is attached a rope by which a man in the pit giving his entire attention to this operation can regulate the swing of the boom to a nicety. By snubbing this line about a post set firmly in the ground, hauls can be made in any direction with no inconvenience from the swinging of the boom, and the dumping of the load on the platform can be accurately adjusted. The derrick on an average lift raises material about 25 feet and carries it approximately 85 feet to the sluices. The amount of material handled is generally 500 cubic yards in twenty-two hours. Power is obtained from a 15 H. P. boiler and 8 H. P. double engine hoist, which burns one-half cord of

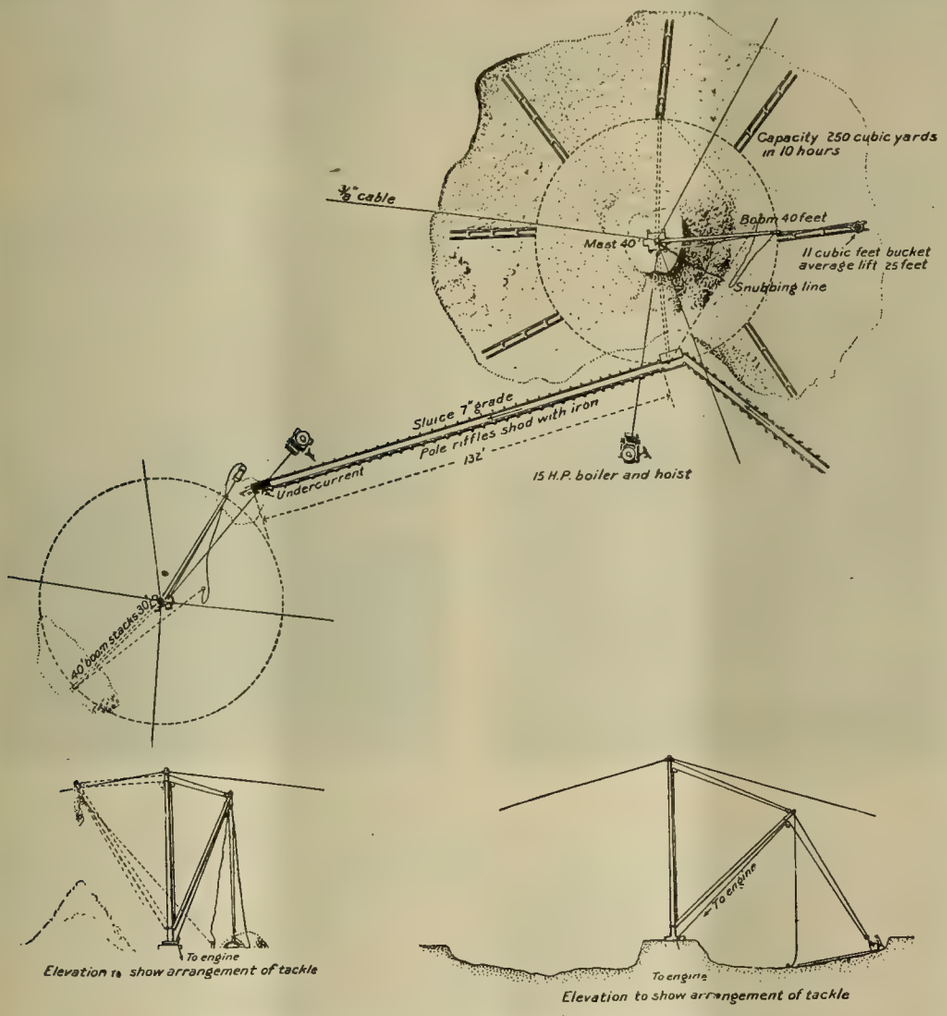


Fig. 6.—Plan of Derricking Plant, Ophir Creek, Seward Peninsula, Alaska.

wood in twenty-four hours at $15 a cord. The derricks are of Washington fir, both boom and mast being 40 feet long. The hauling line, ½ inch in diameter, is of crucible steel wire, plowshare steel not bending easily enough, and the guy lines ⅝ inch in diameter, also of steel, are tightened by watch tackles.

Stones over 12 inches in diameter are not sent through the sluices, being piled by hand in the center of the pit. Larger stones and boulders are handled by the derrick and piled in the same manner. The removal, however, of stones exceeding two tons in weight is not attempted with the derrick. A move is necessary each thirty days, and in advancing the entire plant approximately 110 feet eighteen hours are generally consumed. An auxiliary flume and dump box must of necessity be used to permit such rapid change.

The dump box, which is furnished with a platform sufficiently large to prevent spilling of material, is from 6 to 12 feet above the ground. It is 16 feet long and has a grade of 14 inches. Below it are 132 feet of boxes, 20 inches deep and 16 inches wide, with a grade of 7 inches to the box length (12 feet). These are furnished with pole riffles made 2 inches square, capped with iron, and will last two seasons. At the end of the string is a very efficient undercurrent, invented on the ground. It consists of an ordinary sluice box furnished with iron bars approximately ⅜ or ½ inch in diameter, running lengthwise with the box and placed side by side. Beneath these bars, held by Hungarian riffles, is a quantity of quicksilver, which catches any gold that may have passed the preceding string. Such an arrangement, though of considerable use when gold is generally coarse, will not serve when fine gold is encountered. An undercurrent of greater surficial area and greater grade, carrying the water in a thin sheet, would then be demanded.

In washing the gravel 150 miners' inches are used. The water is brought from Ophir creek in a ditch 1½ mile long. It is 6 feet on the bottom, 9 feet on top, and has a grade of $\frac{1}{10}$ inch to 100 feet. It cost $8000.

Tailings are handled by a derrick and a self-dumping scraper. Power is supplied to the latter by hauling directly from the derrick boom, and its operation is directed by two men. In this case the derrick leans toward the dump pile, to which it carries its load by gravity, being hauled back by the steam winch. To the scraper is attached a rope which, on tightening as the derrick swings, dumps the load at its destination. (See Fig. 6.) Both the derrick boom and mast are 40 feet long and are arranged like the excavation derrick, except that the mast leans in the opposite direction. A 15 H. P. boiler and 8 H. P. winch are used, and there are three men on each shift. The tailings derrick is not occupied more than one-fourth the working time of the pit derrick.

In all from fifty-five to sixty men are employed about the plant. A man is continually needed at the mud box to trip the bucket and to feed the gravel as regularly as possible to the sluices from the platform. A winch man is needed at each derrick. A man in the pit devotes his entire attention to the snubbing line, while two men are necessary on the scraper. The latter feature could possibly be improved by some mechanical method not requiring hand labor. Wages are 50 cents an hour, with board, and work is continued eleven hours each shift.

Besides the derrick plant described above, another, seen on Ophir creek, made use of iron skips of 1½ cubic yard capacity, which were run on trucks to the working face, and, after loading, were trammed within reach of the derrick and lifted to the sluice. As nearly as could be learned, while the capacity of this plant was from 15% to 20% higher than the one previously described, the work was not being done so cheaply. In the last case it was necessary to pump the seepage water from the pit, while in the first case all seepage water was naturally disposed of by draining into the peculiar cavernous limestone bedrock. In derricking plants in general, large rather than small buckets or skips are to be recommended, but the various elements of the plant should be so co-ordinated that the capacity of the derrick is not above that of the shoveling and tramming or of the sluice.

The derricking plant seen on Pedro creek, in the Fairbanks district, has been described in connection with the method of using the cable tram and self-dumping bucket in open cut work. Its efficiency was found to be high and its cost low in comparison with this well-known Klondike method. In general, it may be said that derricking is a simple, efficient, adaptable and comparatively cheap method of working open cuts where gravel must be shoveled into the first receptacle by hand and the bedrock cleaned by men.

(TO BE CONTINUED.)

THE agriculturists of the Deer Lodge valley, Mont., who for some time past have been suing the Anaconda Copper Co. for damages sustained to their crops because of smelter fumes, etc., are now in a quandary. That region the present summer has been visited by unusual rainfall, and as a result the crops are abundant — proof positive that it was not the smelter fumes, but the lack of moisture that has diminished their crops. The farmers are now said to be offering to settle on almost any terms.

The Transvaal Gold Mines.

NUMBER II.

Written for the MINING AND SCIENTIFIC PRESS by THEO. F. VAN WAGENEN, E. M.

Here something should be said as to the nature of the formation in which the gold is found. It is called a "banket." The word is Dutch, and signifies a cake that has raisins or nuts or seeds of some kind scattered through it. The Rand banket is really a conglomerate made up of small quartz pebbles (up to 1 or 1½ inches in diameter), tightly held together by a siliceous cement. Three parallel beds or layers of this pudding stone have been recognized by those who have made a study of the formation, one of which is from 12 to 60 inches or even more in width, but does not average over 30 inches, while the other two are narrower. The broadest vein carries from a quarter to a half ounce of gold per ton, while the narrower ones are of higher grade. The metal exists in the cementing material and not in the quartz pebbles. The three beds are separated from each other by bands of quartzite, and the entire zone is bounded on both sides by walls of the same rock. It is universally conceded to be a water formation, but the geologists are not wholly agreed as to the method of its deposition. Writing broadly, it is rarely over 25 feet from wall to wall of the entire mineral formation, and often less. Sometimes one or both of the narrow beds are absent, or so thin as to be economically unworkable. Again, the whole series is, in places, and throughout large areas, very nearly barren of the precious metal. Along the outcrop there were found many very rich spots, as is common with all gold deposits, and underneath these are the bonanza portions of the reef, but unlike the experience in the ordinary gold fissure vein, the payable sections of the Rand banket exhibit great uniformity in the matters of width and grade and continuity of pay ore, within those limits. A very small amount of pyrite was found in the upper parts of the outcrop properties, but as depth was attained the percentage of iron slowly but steadily increased, until in their lower parts and in the "Deeps," it has become a constant component. In certain parts copper pyrites have also begun to appear, and it is generally believed that in due time enough of this metal will be present to seriously interfere with the usefulness of the cyanide process. Up to date the ores of the region have averaged from $7 to $12 per ton in recoverable values. The amount of silver present with the gold is insignificant.

So far the method of treatment has been crushing under stamps, amalgamation on copper plates and a supplementary treatment of the tailings and slimes with a solution of cyanide of potassium. As English companies are great admirers of tonnage, and great believers in fine crushing, the weight of the stamps and the speed of their drop have been increased until a duty of at least five tons per head per twenty-four hours, through a 40-mesh screen, is expected, and is obtained. This naturally has resulted in the production of a very high percentage of fines and slimes, so that the retreating or secondary parts of a Rand gold mill has become a most important affair. On the principle that the best way to clean up a muss is not to make one, it is quite open to question whether, on the whole, fully as high a percentage of recovery could not be obtained by coarser crushing, followed by concentration, with a much larger duty per head of stamp. In some of the mills where the ore showed base metal early in the game, concentration machinery has already been installed with good results, and the concentrates treated by the chlorination process.

Costs (including everything) range from $6 to $8 per ton, and when analyzed are found to consist mainly, as elsewhere, of the two items of labor and management, but at the Rand these items are larger proportionately than is the case in any other part of the gold mining world. As the walls of the reef are very hard, and stand perfectly, the expense of timbering is very small, which is most fortunate, as the country is quite devoid of timber of any kind. With one or two exceptions water gives no trouble. The consumption of steel and explosives is large, because of the hardness and toughness of the rock. The installation of electric lighting circuits for all the main galleries has reduced this item of cost to a minimum. A fair quality of steam coal is obtainable at the mines at $4 per ton, so that power is cheap, as far as fuel costs are concerned. So, if further economies in the district are to be realized, they must be mainly attained in the two items of labor and management, and it is in these directions that the best efforts of those that are in control are being made.

The native is the natural laborer in the Transvaal, as in the rest of Africa. But he is (at his best) only a very poor miner. Naturally and racially shiftless and easy going, he sells to his employer, and grudgingly, only his muscle and time, and not his brain. In Africa the fallacy of cheap and unskilled labor is still believed in, and even regarded as a necessity at the foundation of things. Consequently the Chinaman has lately been introduced there as a worker, in the hopes of exciting the ambition of the native, or of compelling him, through competition, to do better work. The great fault of the negro is that he will rarely stay at his job more than six months at a time, so that he never becomes manually proficient or reliable, and the force at the mines is constantly changing and requiring new training. Moreover, as he exhibits no ambition to accumulate money beyond his immediate needs, which are insignificant, he cannot be induced to do a full or good day's work, even by an increased wage. The Chinaman is not expected to become a skilled workman, in fact is prohibited by law from becoming one, and the change from black to yellow workmen has been brought about only to secure economy as an indirect result from attaining a steady and reliable supply of manually well-trained miners and laborers. It is too early as yet to say to what extent this end has been secured, or is likely to be attained in the future.

In the matter of supervision, an enormous corps of white underground and surface bosses are steadily required, or thought to be, to handle the workmen, the proportion being about one white to ten or twelve negroes or Chinese, and these whites absorb as much wages as the real workers, and add only a minimum of efficiency. The South African managers are earnestly searching for ways and means to alter or improve this system, recognizing that it is an entirely unnatural one, and that it almost exactly doubles the cost of labor at the mines. But there are many obstacles in the way that will be hard to overcome. Unhappy is the land where manual labor is considered undignified or unworthy, of the people who endeavor to advance themselves by means of the toil of an alien and despised race in their midst.

Tailings Wheel, Robinson Mine, Johannesburg, S. A.

Head Frame, City and Suburban Mine, Johannesburg, S. A.

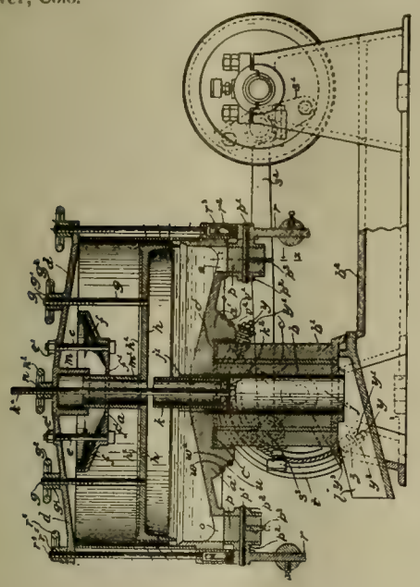
DIAMONDS were mined in India and Brazil long before they were discovered in South Africa, though the latter country has produced by far the greatest mines.

Mining and Metallurgical Patents.

PATENTS ISSUED AUGUST 8, 1905.

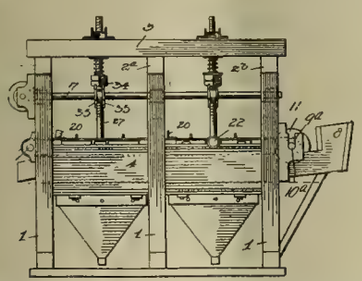
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

ORE CONCENTRATOR.—No. 796,110; I. A. Cammett, Denver, Colo.



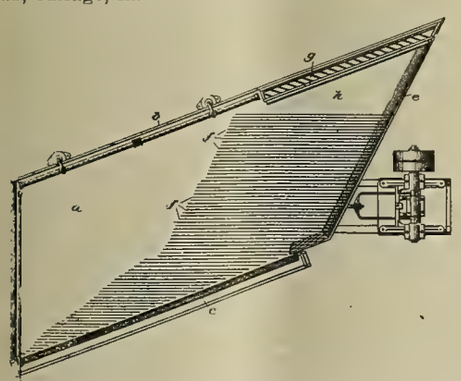
In ore concentrator, combination of bowl, means for producing centrifugal movement within same, discharge opening for waste material from bowl, discharge opening for concentrates in outer portion of bottom of bowl, oscillatory rotary valve for controlling concentrates discharge opening, and adjustable means for limiting rotary movement of valve.

ORE JIG.—No. 796,553; M. P. Baugh, Pueblo, Colo.



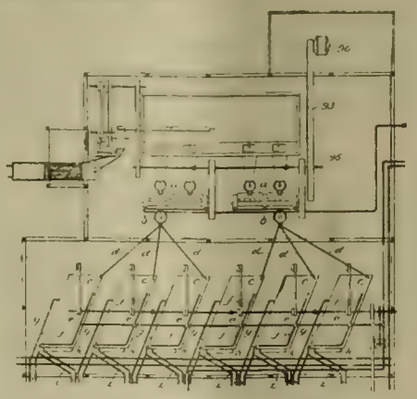
In ore jig, ore screen, hopper beneath same, fluid-forcing means co-operating with hopper, plunger connected to fluid-forcing means and having upper end guided in one of frame members, square collar threaded on plunger above frame member, vertical plate bearing against collar for preventing rotation, and means for operating plunger.

CONCENTRATING TABLE.—No. 796,940; T. F. Sheridan, Chicago, Ill.



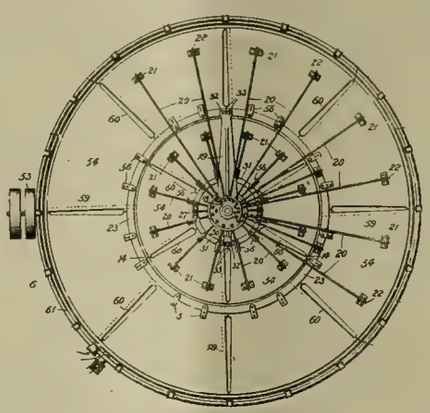
Reciprocating transversely inclined concentrating table having lower side edge and forward end edge in oblique relation to each other, series of riffles of equal length extending from forward end toward rear end of table upon upper portion thereof, smooth surface portion between rear ends of such riffles and rear end of table, and second series of riffles of progressively diminishing length extending progressively from lower side edge of table wholly subtending such smooth surface portion and adapted to return concentrates thereto.

PROCESS OF TREATING ORES.—No 796,754; J. R. Parks, Spokane, Wash.



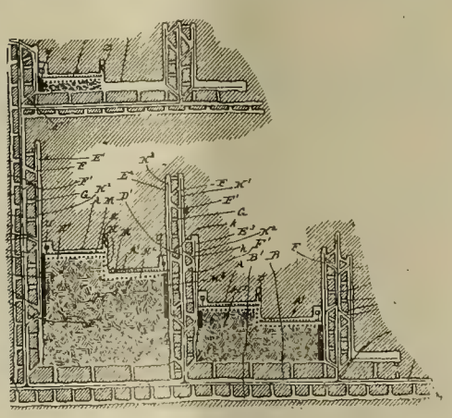
Process of treating ores, which consists in intermixing pulverized ore, cyanide of potassium, and fluid electric conductor and simultaneously passing current of air and current of electricity through mixture and retarding escape of air from mixture.

MACHINE FOR TREATING ORES.—No. 796,753; J. R. Parks, Spokane, Wash.



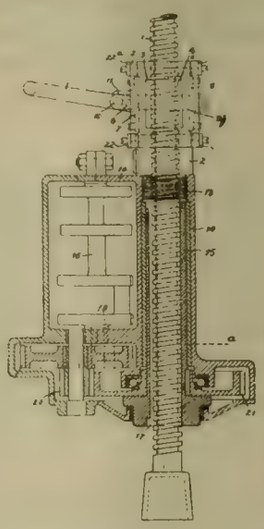
In machine of class described, combination of outer shell forming chamber and provided with inner metallic portion, second metallic element mounted adjacent to such inner metallic portion insulated therefrom and forming chamber between such parts for containing mixture having pulverized ore therein to be operated upon, means for connecting such metallic elements to negative and positive poles respectively of source of electric supply, means for agitating mixture containing pulverized ore to be operated upon, and means for forcing air into chamber formed by shell.

ART OF MINING COAL.—No. 796,499; C. R. Claghorn, Wehrum, Pa.



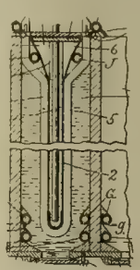
Improvement in art of mining coal, which consists in forming main heading, cross headings connected therewith, two or more of which extend in same direction as sides of relatively wide intervening area of coal, forming clearance space or upriser near each heading, main heading, cross headings and uprisers being relatively deep and provided with track systems, forming two working faces, both transverse to cross entries, breaking down coal along working faces, transporting broken-down coal along one face by endless conveyor in one direction toward clearance space or upriser and depositing coal in cars therein and transporting coal in opposite direction by second endless conveyor extending from opposite heading and delivering coal to cars in clearing space adjacent to heading.

ROCK DRILL.—No. 796,890; J. T. Blackett, Guisborough, England.



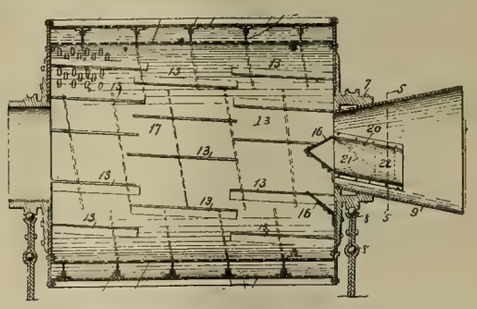
Combination with revoluble feed screw, of stationary feed nut casing, feed nut formed in two sections which engage with screw and which are slidable in casing, operating lever pivoted to one nut section, link extending crosswise of feed screw and pivoted to lever and to other nut section, and stop arranged in path of last nut section.

APPARATUS FOR TREATING SLIMES IN ORE REDUCTION.—No. 796,503; G. A. Duncan, Deadwood, S. D.



Apparatus for treatment of ore slimes, consisting of filtering cell having length and breadth respectively horizontal and vertical and thickness small relatively to other dimensions; tank in which such cell is suspended and which accommodates same with relatively small space at opposite sides; suction pipes intruded into cell from top, terminating open near bottom; means for producing suction through such pipes and means for supplying slime-bearing liquor to tank and for aerating same from bottom.

APPARATUS FOR PLACER MINING.—No. 796,780; J. L. Weaver, Boise, Idaho.



Screen provided with inner foraminous cylinder having series of angular or inclined flights on inner side overlapping at adjacent ends, outer and concentric foraminous cylinder or wall, screw between walls, approximately volute discharge vanes at one end, and spout having central discharge for coarse material, and provided with opening in wall for discharge of finer material.

PROCESS FOR THE TREATMENT OF ORES CONTAINING ANTIMONY.—No. 796,849; J. S. MacArthur, Glasgow, Scotland.

Process for treatment of ores containing antimony, consisting in, firstly, treating ore with solution containing not more than 4% of caustic soda, solution being meanwhile maintained at temperature exceeding 50° centigrade, whereby antimonial content is dissolved; secondly, precipitating, by carbonic acid gas, antimony from antimonial solution thus obtained and forming at same time carbonate of soda therein; thirdly, regenerating alkali solution by treatment with lime.

MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

ARIZONA.

Cochise County.

(Special Correspondence).—The Tombstone Con. M. Co. is opening up new ground with satisfactory results. A rich strike was made recently in the shaft of the company between the 600 and 700 levels. Regular shipments are being made from the various mines of the company at the rate of three cars per day. An additional oil tank is being built which, when completed, will have a capacity of 104,000 gallons. This is being done so as to provide against washouts and delays. The additional pumps which were ordered recently arrived and will be put in at once and will increase the pumping capacity to 6,000,000 gallons per day. Work on remodeling the old Girard mill is progressing rapidly, and it is expected that it will be completed and its additional stamps added within three months, at which time the concentrator, which is being built on the grounds, will also be finished.

Tombstone, Aug. 21.

Gila County.

The Silver Belt in describing the hopper scale charge weighing appliance at the Old Dominion smelter at Globe, put into operation during the latter part of June, says that the different ingredients of the charge, such as all classes of ores, oxides, sulphides, acid flux and limestones, the black copper slag, coke, etc., each have their respective pockets in the large ore bins into which they are delivered from steel hopper bottom cars, each material being provided with four chutes, which, on opening the gate, deliver their material to a steel hopper, which takes the place of the platform of an ordinary scale of 2500 pounds capacity, and is allowed to run therein until the beam indicates that the desired quantity has been received. The charge train of three cars and an electric motor passing under the hopper scales, stops and receives three charges of coke, then limestone, ore, sulphides, old slag, etc., in such quantities as the metallurgist may designate and takes them to the furnaces. Manual labor is reduced to a minimum, the varying weights of the different cars have no effect on the charge contained, and an error in any one of the component parts does not affect any of the remaining ones, which was always the case with the old system where too much ore meant too little coke, or vice versa.

Mohave County.

Work has been temporarily suspended at the Blue Ridge mine and mill near Vivian. —— C. D. Pickering, superintendent of the Yucca Cyanide M. & M. Co.'s San Francisco mine at Cedar, reports that the mine on the lower level is showing up good bodies of ore. A 50 H. P. compressor and machine drills are to be put in at once and work on the mine rushed.

Pima County.

(Special Correspondence).—The Helvetia C. M. Co.'s Isle Royale shaft at Helvetia is down to the 800-foot level and crosscutting has been started. The mines are in the Santa Rita mountains, 35 miles southeast of Tucson. The nearest railroad station is at Vail, 16 miles from the mines. The formation resembles that at Bisbee, the carboniferous limestone being of the same geological horizon with similar porphyritic intrusions. The ores turned to sulphides on the third level. A 2¾-mile railroad connects the mine and smelter. The first smelter was burned in 1900 and rebuilt in 1901, the present plant having a daily capacity of 150 tons. The furnaces are to be started before November 1 on ore now being blocked out. Crosscutting has been started at the fourth level down. Water has been struck at the bottom of the shaft and will be pumped and impounded for smelter use.

Helvetia, Aug. 20.

Pinal County.

(Special Correspondence).—Superintendent A. C. Seiboth of the Lake Superior & Arizona M. & S. Co. received returns recently from a 30-ton shipment of ore to El Paso that netted the company over $70 a ton. This company has recently opened up a large body of gold ore. The mines are in the Pioneer district, near Florence. The property shows three copper ore bodies, mainly in limestone, near a quartzite contact. The ores are mainly oxides and carbonates, associated with iron and manganese.

Florence, Aug. 21.

Santa Cruz County.

(Special Correspondence).—The Grubstake gold and silver mines of Oro Blanco have passed into the ownership of the Grubstake Con. G. M. & M. Co.

Oro Blanco, Aug. 21.

Yavapai County.

The shaft of the Bauman Copper Co. at Dewey is below the 300-foot level and will be continued to the 1000-foot level, making short crosscuts at each 100-foot level. The country rocks are quartz, porphyry and slate, the principal veins occurring as fissures in quartz porphyry, with heavy gouge in foot wall. The ores are cuprite, malachite and azurite above, with chalcopyrite below. W. H. MacKay is superintendent. —— At Crown King the Ore Bell has eighty men working in the mine and 10-stamp mill. The Crown King is regrinding and retreating the tailings.——Manager Timmons has ten men working at the Gold King, near Crown King.——The 10-stamp mill at the Lincoln is to be started as soon as new boilers have been put in.

CALIFORNIA.

Amador County.

The strike of the Amador Miners' Union against the Fremont M. Co. of Amador City has been officially declared off.

Calaveras County.

At the San Andreas Gold Quartz mine, John L. Henry has put up a gallows frame and whim. When the shaft is down a sufficient depth to admit of crosscutting, a larger force will be put on.——Active operations are to be commenced at the Round Butte mine, near San Andreas. The property is under the management of James Stewart. The first work to be done will be the sinking of five shafts on the property.——The Yellow Boy M. Co. of Salt Lake City is operating the Red Gold mine, west of Murphys, and the Gum Boot, on San Antonio creek.

El Dorado County.

It is reported that another rich body of ore has been struck in the Union mine, El Dorado district.——At the Cedar Creek mine, Fairplay district, the tunnel is in 100 feet of the 750 feet necessary to tap the channel.

At the Havilah mill, near Nashville, twenty stamps are dropping on ore from the mine, where seventy men are at work.——It is reported that a mill is to be put on the Last Chance mine, 6 miles north of Plymouth. The shaft is being sunk by Manager Smith.

Manager F. M. Curtis is putting in an auxiliary steam power plant at the Red Raven mine, near Placerville. This will run the 10-stamp mill when water power is not available.

Placer County.

The Rawhide mine, near Towle, on the American river, has reopened under the management of the original Rawhide M. Co. Since the failure of the Soldon M. Co., at the expiration of the year for which it had bonded the mine, all work has been suspended. John Mottrom has been elected president of the old company.——The Whisky Diggings mine, 9 miles northeast of Lincoln, has been reopened by a company of San Francisco men, who will sink the old shaft to a depth of 1200 feet. A new hoist and other machinery is being put in.——At the Evening Star mine, on Rock creek, work is being carried on on the 60-foot level.——The Lewis Hill Gravel M. Co. is developing its mine, 3 miles below Newcastle. The work is in charge of R. M. Mooer of Auburn. The lower tunnel is in 380 feet and the upper one 120 feet. There is an upraise of 70 feet, which furnishes fresh air.

Plumas County.

W. P. Hammon is interested with H. H. Yard and J. H. Leggett in a large dam being built to increase the storage capacity of Silver lake by raising its surface 6 feet. Five thousand horse power of electricity will be developed by the water from the lake, and this will be used to operate a system of electric cars that will convey the sand and gravel on the claims held by them from the place of excavation to the points where water will be available for washing it. The claims are in canyons and on hillsides and cannot be worked by the dredger.

Shasta County.

The rates the Mammoth Copper Co. has established for treating siliceous ores at the smelter at Kennett may vary from time to time, but those now offered follow: Ore from $3 to $15 a ton in assay value will be smelted free and 75% of the value returned to the shipper. On ore between $15 and $25 a ton 77½% of the assay value will be returned and there is no charge for smelting. Ore from $25 to $50 per ton, 90% returned; $3.50 a ton smelting charge. Ore from $50 to $75 a ton, 95% returned; $5 a ton for smelting. Ore from $75 to $100 a ton, 95% returned; smelting charge $7 a ton. Ore from $100 to $200 a ton, 95% returned; smelting charge $10 a ton. In addition to the above percentages of gold, 90% of all silver assays will be returned on all ores carrying over five ounces of silver. If less than that amount of silver is contained in the ore, according to assays, no returns will be made. Only siliceous ores going as high as 90% in silica will be treated free. Ores deficient in silica are subject to a charge for smelting. Gold will be paid for at the rate of $20 per ounce and silver at the current New York quotations. Ore must be shipped in lots of not less than ten tons.——Work is progressing rapidly on the aerial tramway to supply the smelter with ore from the Mammoth mine.

Sierra County.

(Special Correspondence).—At the White Bear gravel mine, north of Downieville, Superintendent Wm. J. Belcher finds that a small part of the gold is left in the tailings and has decided to impound them, as the gold may be recovered after the clay has been weathered. The flume is to be lengthened.——The Forest City M. Co. have cut two quartz ledges in their main tunnel being driven to open up the old Mabel Mertz, near Forest City. Superintendent H. B. McCormack is employing ten men and will start an upraise soon. This is a drift mine and heretofore little attention has been paid to quartz.——It is claimed that the Bald Mountain gravel channel has been tapped by the 2500-foot tunnel of the South Fork drift mine at Forest, after twelve years of work. Fred Kuhfeld is superintendent.——At the Lucky Dog drift mine, 2 miles west of Forest City, the channel has been found, after being cut out for a long distance by lava.——W. J. Finney, superintendent of the Telegraph Drift M. Co., purchased an electric plant for the Telegraph mine, north of Downieville. This mine has both quartz and gravel, and is equipped with a 5-stamp mill. The new power plant will be used for milling, ventilation and pumping. —— T. J. Lamouroux has taken a bond on the property of the Sovereign G. M. Co., near Downieville, and will put up a 10-stamp mill.

Downieville, Aug. 21.

R. J. Fitzgerald has bonded the Carson mine at Allegany.

Trinity County.

The hydraulic mine, originally operated by Fordyce Bates and J. F. Tourtelotte at Minersville, has been bonded by A. F. Johnson, who has men cleaning up preparatory to putting in a hydraulic elevator.——The La Grange Hydraulic M. Co., operating the placer mine on Oregon Gulch mountain, near Weaverville, has started repairing the flume from near the head of Stuart's Fork to the great inverted syphon across that stream, below Van Metre creek. The water supply system of the La Grange mine includes the large inverted syphon, 35 miles of flume and ditches and a 10,000-foot tunnel.

At the Headlight mine, near Trinity Center, eight men are employed under Frank Kidd. A tunnel is being driven to cut the vein.——Work has been resumed on the Dorleska mine on Coffee creek.——The dredger on the Trinity, above Trinity Center, is running steadily with four men under Superintendent G. W. Payne.

Tuolumne County.

At the Clio mine, near Jacksonville, a level has been made at the 400-mark and sinking to the shaft will continue.——At the Horse Shoe Bend mines, near Columbia, E. A. Skewes of Liverpool, England, has started grading for the mill.——After a thorough overhauling the mill at the Del Monte mine, near Groveland, has been started. At the mine the pump has lowered to the bottom of the main shaft. On the 90-foot level, 100 feet east of the main shaft, an upraise is being made. H. M. Stanley is superintendent.——At the Cosmopolite mine, at Groveland, eleven men are at work in the lower tunnel. A crosscut is being run 94 feet from the mouth of the main tunnel, while old timbers are being replaced with new. Superintendent Wm. Pool is in charge.

Yuba County.

At the Peerless mine at Smartsville the shaft has been cleared. A gasoline engine has been put in to handle the debris and water in the shaft.

COLORADO.

Boulder County.

A half interest in the Livingstone mine, near Boulder, has been sold by W. R. Doty, who retains the other half, to F. G. Shaffer of Denver.——The Potato Patch, as it is familiary known to the mining world, was at one time worked with plows and scrapers and the earth loaded in wagons was sent to the smelters and brought the owners over $200,000. Since that time the vein in place has produced over $200,000, and the deepest workings on the property are less than 300 feet.——The Good Morning tunnel, which enters Sugar Loaf at Wall Street, 8 miles above Boulder, is to be driven 6000 feet to tap the Gladys, Ragged Top, Livingstone and Cross and Sphynx properties. All of these properties have been profitable and heavy producers, and were recognized as such until the question of water in the workings became such an expensive one.——The Livingstone property has three shaft houses, a mill and a power plant. New machinery is to be added.

The Cash mill at Magnolia has, according to recent accounts, solved the problem of ore treatment in that camp by oxidizing the telluride products in a roasting cylinder and then cyaniding. The Boulder Times says that F. A. Leonard, the manager, has met with such success that he has decided to put in two more leaching vats. He has made a saving of 95% and $30 ore is being treated in the mill instead of being shipped to the smelters. The fuel used is crude petroleum from the Boulder oil wells. The amount treated is fifteen tons per day, but when the new leaching vats are in place the capacity will be doubled.

Clear Creek County

A strike of high grade gold, silver, lead and copper ore is reported from the Little Flat mine, in Cascade creek, in the drift being driven east from the 400-foot level. The mine is owned by the Allen M. Co., J. B. Allen of Idaho Springs being resident manager. It is the intention of the company to build a concentrating mill on Chicago creek when a sufficient amount of ore has been blocked out in the mine. The property will be cut by the Burns-Moore tunnel within the next few months and operations will also be carried on through that outlet at a greater depth.

The U. P. R. lode, one of the earliest discoveries on the western slope of Bellevue mountain, near Idaho Springs, has been cut by the Lucania tunnel, 2100 feet from the portal, and at a depth of nearly 1000 feet.——The Queen of the West mine, on Argentine Pass, has been leased to Thos. Cunningham, who will start development.——Work has been resumed on the Ramsdale claims, located on Lincoln mountain, near Georgetown, by G. W. Teagarden and A. B. Montgomery. A power plant is to be put in near the mouth of the 400-foot crosscut, together with an air compressor and machine drills.

An 8-drill compressor and steam power plant is to be put in by the Banner Con. Co. for the Rockford tunnel, near Idaho Springs. The tunnel is to be driven to the heart of Donaldson mountain and has already been run 1000 feet, about 2500 feet remaining to be driven.

Gilpin County.

The Register Call reports that the Petersen mill in Lump gulch, near Central City, has been leased by Manager Frank Augustus of the Colorado M. Co. and A. C. Dart has been placed in charge. It is equipped with fifteen slow drop stamps and has a daily capacity of twenty-five tons, is equipped with bumping tables and was last run on ores from the Gold Dirt mine, on which a very good saving was made during the three months in which tests were made with the cynanide process. The mill has been leased for the purpose of treating the ores from the Colorado tunnel property of the Colorado M. Co.——A new shaft building 20x40 feet has been put on the Daisy Extension mine on Perigo hill in the Independent district, by J. A. Gilmour of Central City, who is the owner and operator, and an 8x10 double cylinder hoister of McFarlane manufacture has been put in, together with a 35 H. P. boiler. The shaft on this property is down 125 feet and has been repaired and cleaned. A contract is to be let for sinking the main shaft another lift of 100 feet.

At Russell Gulch, Manager Nickerson of the Fairfield M. Co. is asking for bids on putting up a shaft building 45x40, to replace the one burned last month, as well as for a gear hoist 8x10 and a 60 H. P. boiler.——The Fostoria G. M. Co. is putting in machinery in the Silver Gem tunnel, near Gilson gulch, to operate its Summit group, in the Pleasant Valley district.

Development work is being carried on at the property of the Twolon Gold M. Co., known as the 2:40 mines in Willis gulch, under the management of Stephen Hoskin of Central City. Operations are being carried on in the 200 and 350-foot levels, and a few leasers are at work. ——At the Alps mine on Quartz hill, near Central City, operations are being carried on at a depth of 600 feet in the main shaft and also at a depth of 1300 feet in what is known as the submarine shaft. The property is being

worked under a lease and bond from Hal Sayr and associates by a local pool, of which James Williams is superintendent.——Leasers are at work at the Eldorado mine in Russell district, which is operated by the Eldorado M. Co. The company is arranging for the resumption of operations on their Lynn shaft, the main shaft being down 200 feet and is to be sunk deeper. S. T. Harris is in charge.

During the second week of this month the shipments of smelting and crude ores, tailings and concentrates to the Denver smelters and to outside points from Central City were seventy-two cars, or 1510 tons. The following shipments were made to Argo: Druid mine in Willis gulch, two cars; one car by Martin & Co. of the Puzzle mine on Bobtail hill, one car of enargite ores from the Powers mine, Russell district; one car from the Imperial M. & M. Co., operating in the Pine Creek district, and one car of 10-ounce ores from the East Notaway mine in Russell district, besides two cars of zinc ores from the Ivanhoe mine on Quartz hill to the Lanyan Zinc Co. of Iola, Kans. —— At a stockholders meeting of the Pewabic Con. Gold Mines Co. the following officers were elected: President, general manager and treasurer, J. C. Fleischhutz; secretary, W. A. Funk. The plans as submitted by Manager Fleischhutz for the increased development and operation of the properties have been approved. They include operation on the base of Pewabic mountain through two working shafts, the main Pewabic and the Iron. A new and complete hoisting and compressor plant is to be put on the Iron at an early date. Shipments are being made to the New York mill at Black Hawk, under lease and option by the Pawabic company.

Gunnison County.

A rich strike of gold ore is report d from the property of the Gold Vein M. Co. on North Cross mountain, near Tin Cup. C. F. Wahl of Tin Cup is superintendent.——George Brant has started work on the Copper Sulphide lode, near Bowerman. A shaft is being sunk. He is also doing work on the Gold Ridge lode.——A lease and bond have been secured by A. B. Coats and Jas. Henry on the Nettie lode, near Bowerman.——The Augusta mine, near Crested Butte, has been temporarily closed. ——Horace Miller has started work on the Hard Cash and Mexican mines on Galena mountain, near Crested Butte.

Hinsdale County.

Increased work is to be done by the Golden Fleece Con. Co., near Lake City. T. B. Stearns has charge of work.——Machine drills are to be put in at the Moro and Ajax mines of the Hanna M. & M. Co. by Manager G. H. Martin.

Larimer County.

The Pearl smelter is completed and equipped, and will begin ore reduction not later than September 15. The smelter has cost $100,000, and will begin by reducing 3000 tons per month. The works at present will make 55% copper matte, a bullion converter being probably added next year. Ore is being gathered and coke and charcoal arranged for.

Mineral County.

(Special Correspondence).— Mining in the southern part of the State is in a healthy condition. During the past year a large amount of development work has been in progress, and as a result of the development in the mines several mills are being erected for the treatment of the ore. In the Creede district there has been a scarcity of men and as a result the mines have not been able to operate full capacity. It is understood a survey is being made from Creede to Durango with the idea of making a standard gauge road to connect with the new branch of the D. & R. G. Ry. now being built south of Durango. The road from Denver to Creede is standard gauge.

Creede, Aug. 21.

Ouray County.

(Special Correspondence).—The Treasury Tunnel M. & R. Co., W. J. Hammond, Jr., manager, are preparing to add twenty more stamps to their 20-stamp mill. An electric motor for delivering ore from the mine to the mill is to be put in later on.——The Joker tunnel, which is being driven by W. C. Aston, intends putting in an electric motor to facilitate the work in the tunnel.

Red Mountain, Aug. 19.

(Special Correspondence).—In the Red Mountain district, on the Ouray side, the Barstow, Treasury and Crawford companies are doing an immense amount of work. The Barstow Co. is operating thirty stamps on ore from their mine, and the Treasury Co., under the management of W. J. Hammond, Jr., is adding twenty more stamps to their mill which now contains twenty stamps. For a time there was difficulty with some of the men at this property over wages, the men claiming they were obliged to work in a wet place while the management contended otherwise. The difficulty, which was not great, has been disposed of, and the property is being operated full capacity. Across the gulch from the Treasury is the Genessee, Guston and other properties of the Crawford Syndicate, which are being developed as rapidly as possible. They are driving the Joker tunnel, to be used as a drainage and transportation tunnel. This tunnel starts 1 mile above Ironton and is 12 feet by 14 feet outside the timbers and double tracked. The tunnel is now in 2000 feet and being driven at the rate of 9 feet per day. A crosscut is being started from the main tunnel to connect with the Guston workings, and is expected to tap the Guston at a depth of 600 feet. About 1200 feet farther the main tunnel will cut the old Yankee Girl at a depth of 800 feet. The breast of the tunnel is broken with nineteen holes, using an upper cut. An electric motor will be put in to handle the rock from the tunnel. W. C. Ashton is superintendent.

Red Mountain, Aug. 21.

Rio Grande County.

At Summitville, the Gold Crown M. Co. has taken a bond and lease on the Esmond, one of the oldest mines in the camp.——At Summer Coon, 6 miles north of Del Norte, there are strong veins carrying galena and iron. The Esther M. Co. is taking out gold, silver and lead ore, but there is no mill in the camp.——At Embargo, the Washington Gold M. & M. Co. is sinking on its Evening Star and drifting from the 170-foot level. The Golden Income Co. will begin work soon. The manager of the Tornado M. Co. of Terra Haute, Ind., has been working all summer on the Black Hawk at Embargo. On the Mesa, Hurm & Haskins are developing the Caddie, where the shaft will be sunk to the 100-foot level on an incline.

San Juan County.

(Special Correspondence).—The Ledge M. & M. Co. is being operated this year by Kramer Bros. & Carmichael and is averaging about 100 tons of lead concentrates and 50 tons of zinc concentrates per week; the zinc will run about 50%. Only a portion of the mill is being operated at present.

Silverton, Aug. 19.

(Special Correspondence).—About 16 miles north of Rockwood the Delayed M. & M. Co. is driving a tunnel 7x7 feet which gives them 120 feet depth. Some very rich assays are reported by E. L. Thompson, manager of the property. The ore carries copper, gold and silver. Where this property is located there has been but little prospecting done for a number of years. The mine is on the west side of the West Needles. Buffalo, N. Y., parties are interested. Another tunnel 900 feet in length is to be started to tap the mountain at a depth of 500 feet.——Near Animas Forks the Gold Prince Co. are developing their mine, operating their old mill and breaking ground for their new 100-stamp mill to be built at Animas Forks. The frame work will be of steel and foundations of concrete. At present 160 men are employed in preparing the foundation and excavating. O. O. McReynolds, chief engineer on the works, expects to have the mill ready to receive the machinery by Dec. 15th this year. An aerial tramway is being built from the mine to the mill. Power will be supplied from the electric plant at Rockwood, below Silverton.

Silverton, Aug. 21.

Summit County.

Near Kokomo, in Mayflower gulch, the Thomson M. & M. Co. is driving the Bird's Nest tunnel.——Ore bins are being put up on the Result mine on Gold hill, near Kokomo. M. Hyman of Denver is interested.——The tunnel of the Union Con. group on Gold hill is being driven under the management of M. Gagan.

Teller County.

The 300-foot shaft in the South Burns claim of the Acacia is to be continued to the 800-foot level by the Exposition M. & L. Co. of Cripple Creek.——The property of the Wheel of Fortune M. Co. has been sold at sheriff's sale to satisfy a judgment of $2621.54 held by Wm. Helm, who purchased the property.——Surface water around Independence has been causing considerable trouble to several properties. The Independence Con. Co. has been forced to start its pumps and is drawing between 200 and 250 gallons of water per minute.—— The Golden Cycle M. Co. has decided to put up a cyanide plant of 200 tons capacity either on the company's property at the mines on Bull hill, Cripple Creek, or at Colorado City. The bromo-cyanogen process will probably be used.——J. Emerson, who is operating under lease the Murphy shaft on the Bull hill property of the Stratton–Cripple Creek M. & D. Co., has started shipping, after having been closed down for some time on account of the surface water.——Ore bins are being built on the east end of the Rocky Mountain property on Beacon hill, Cripple Creek.

IDAHO.

Blaine County.

Superintendent Allen has prepared specifications for a concentrator at the Hillside mines, in Lee's gulch, near Hailey. The 170-foot raise in the mine to connect the tunnel with the surface has been completed, and is to be continued in depth as a shaft 200 feet below the tunnel level.——A road is being made to the Lucky Boy mine, west of Ketchum, so that ore shipments can be made.

The Boulder Con. M. Co., operating on Boulder creek, 25 miles north of Hailey, is going to drive a tunnel from the Wood river side of the Boulder range to the East fork of the Salmon. The tunnel will be over 5000 feet in length and cut the formation at a depth of 2800 feet. It will prospect, drain and develop a large extent of mineral-bearing ground.

Idaho County.

In the Thunder Mountain district it is reported that the mills of the Standard, Sunnyside and Dewey properties are closed for the present, but the mines are being developed. The ore seems to have become refractory with depth, and experiments are being made to get the values from the slimes and tailings.

Shoshone County.

V. C. Hikes, of the Geological Survey, who has been making examinations of the placer gravels through the West with the view of determining if rare metals were likely to be found in them, reports that tantalum has been found in sands from Snake river and in the Pierce district.

The Monitor mine of the Monitor Con. Copper M. Co., 5 miles west of Saltese, Mont., is shipping regularly to the Tacoma smelter. Otis Hill of Tekoa, Wash., is managing director.

Regarding mineral production of the Cœur d'Alenes, the Idaho Press says that the shipments to smelters of ore and concentrates for the first seven months of 1905 aggregated 175,000 tons.——The California will soon have its electrical equipment put in and its enlarged mill ready to treat its newly found bodies of galena, besides being in shape to secure a much higher extraction from its carbonates.— The Success Co.'s mill will be in operation probably within another week.——The Hercules mill will also be in operation in a short time.——The Snowstorm is arranging for an increased output of both first and second class ore, and numerous other properties, such as the Rex, Chesapeake and Tamarack and a half dozen mines of the North Side, will ship.

MICHIGAN.

Houghton County.

(Special Correspondence).—The Manitou and Fontenac copper mining companies, recently organized to develop and operate copper mines on the Keweenaw peninsula, are controlled by the Calumet & Hecla Co. The Calumet & Hecla has recently secured control of 60,000 acres of mineral land, originally held only for the timber on it. There are many test pits on this tract and some good prospects for copper rock. This work was done in early days, when it required a much higher grade of rock to pay a profit than now. The conditions surrounding the industry have changed and rock that now yields anything above 1%, by the use of modern machinery and large tonnages, can be made to yield a profit. Exploratory operations have been started on the properties. It was known that several lodes cross the property which the company had acquired, but their value can only be determined by extended exploration. The general character of the amygdaloidal beds yields easily to milling processes. If this state of affairs exists to any great extent, even if the percentage of copper per ton is small, the rock should be capable of showing a profit if worked on a large scale.

Houghton, Aug. 18.

Following the mineral extension of the Mineral Range R. R. to shaft C, the extreme west opening on the Mass property, the company let a contract for a permanent rock house at the shaft, construction to begin immediately. On the railroad extension the grading is completed and the laying of rails is in progress. Shaft C is 100 feet above shafts A and B. The showing of the two lodes that are being worked through the shaft are good. At the present time only one head of the stamping capacity of the mill is available, but it is possible to handle a slightly increased capacity over what is being treated at the present time. The compounding of the stamp head, which has been under discussion by the management for some time, would probably follow closely a production which the mill is unable to handle. Such an improvement, at a cost of about $10,000, would increase the capacity of the mill about 200 tons per day.

MONTANA.

Fergus County.

A suit is now on trial in the Lewiston district court, the action being brought by I. F. David, a rancher on the Judith river, against the New Mines Sapphire Syndicate, owning and operating the sapphire mines at Yogo. David claims that by reason of a waste ditch from the mines, which discharges into the river above the intake of this irrigating ditch, a vast amount of the waste has been carried upon his land, where it has formed a cake, being, according to the exhibits of squares of earth offered in court, all the way from a few inches to a foot thick. The plaintiff and his witnesses, all of whom are ranchers, assert that this deposit forms a hard cake over the soil, which speedily chokes out the crops, and it is also claimed that the deposit in the bed of the river has changed the channel below the point of discharge. The plaintiff contends that the present plan of getting rid of the waste can be changed without interfering with the operation of the mines if the defendant will convey the waste upon its own lands. The defense will claim that the waste, so far from being harmful, is really beneficial to the land, acting as a fertilizer.

Granite County.

At Royal a cyanide plant is being put in to work the tailings from the Royal mill. J. Terry of Butte has charge. Pyke & Lindquist, leasing in the mine, have twenty men at work.

Madison County.

The Pony Sentinel reports that bullion to the amount of $15,850 was shipped in one week from the mines around Pony, in addition to the shipments of concentrates and ore. In the Pony and South Boulder districts fifty stamps are dropping constantly and several cars of concentrates and shipping ore are sent to the smelter at East Helena every month. The Clipper group, discovered in 1877, and owned by the Indian G. M. Co., is leased by Elling & Morris, who have ten stamps dropping at the mill.——At the Garnet mine, of which F. C. Wood is the president, twenty stamps are dropping.—— At the properties of the Mammoth M. & P. Co., on the head of the South Boulder, near Pony, the company has ten stamps dropping.——At the Lennstrende–Buck property, between the Pony mines and those of the Boulder section, a 5-stamp mill has been put up.

Missoula County.

Work has been resumed on the Montana Standard mine, 11 miles from Thompson. Work on a flume 2 miles long has been started. This flume will take the water from Crow creek and will be utilized for power for a compressor. Work has been resumed by hand in the No. 3 crosscut tunnel, which is being driven to tap the ledge at a depth of 800 feet. As soon as the new compressor is put in, a contract to extend this tunnel 1500 feet will be let. John Murphy is the principal stockholder.

Park County.

In the Crevasse mountain district, near Jardine, the Conrad–Stanford Co. intend putting in a new stamp mill and adding concentrators to the present mill.

Silver Bow County.

In the injunction suits brought by an association of farmers against the Washoe smelter of the Amalgamated Company, the farmers are seeking to close the smelter permanently, and claim that their farms have been ruined by the smelter smoke and poisonous refuse. Before suits were brought they offered to settle for less than $1,000,000, but they now want $2,000,000. In their testimony and pleadings before the Federal court they represented that nothing will grow in the smoke district, covering many miles, but this season has been the most profitable the ranchers in that part of the State have ever known, and crops have grown so rank and plentiful as to create despair among the farmers who have been trying to settle with the company. There has been an unusual rainfall this summer.——It is reported that the Pittsmont smelter of the Pittsburg & Montana Co. is again closed down temporarily, making the eighth break down since the smelter was started. A new blower is to be put in.

NEVADA.

Lyon County.

Surveys are being made for work at the Hayward mine and Eureka mill, at Silver City. J. E. Munroe has charge of work.

Nye County.

At Liberty, 20 miles north of Tonopah, among the properties being worked are La Libertad, under the management of W. C. Wynkoop, with a 485-foot shaft, the Callington and the Cedric under Albert Weaver, the Florence Extension, with a 115-foot shaft, the Tonopah Berkeley with a 150-foot shaft, in charge of L. C. Orndorff, and the Oregon and St. Paul.

NEW MEXICO.

Santa Fe County.

A strike of molybdenite is reported 6 miles from Santa Fe, on ground belonging to the Santa Fe Water Co., by Frank Owen. A rush is being made for the district and over 400 acres have been located. The strike was made at a depth of 40 feet.

OREGON.

According to E. W. Parker, in his report to the United States Geological Survey, the total coal production of Oregon in 1904 was 111,540 short tons, valued at $243,588. The only productive coal field in Oregon is in the southwestern part of the State in Coos county, and is known as the Coos Bay field. It occupies 250 square miles, its length north and south being 30 miles and its maximum breadth at the middle 11 miles, tapering regularly toward both ends. Other coal fields have been prospected in different parts of the State, and some have been shown to contain coal of fairly good quality. Among these are the Upper Nehalem field, in Columbia county; the Lower Nehalem field, in Clatsop and Tillamook counties; the Yaquina field, in Lincoln county, and the Eckley and Shasta Costa fields, in Curry county. All of these fields lie west of the Cascade range, but none has been developed to the point of production. Another field has been located in the basin of the John Day river, east of the Cascade range, but little is known concerning it. All of the fields west of the range, with the exception of the Coos Bay, are of limited area, the largest, outside of the Coos Bay, being the Upper Nehalem, which has an area of less than 20 miles. All of the coal of these fields is lignitic in character. Transportation is confined exclusively to Coos bay and the Pacific ocean, and San Francisco is the principal market. The Coos Bay field is divided by its structure into six portions—four basins and two arches. The basins are known as the Newport, the Beaver slough, the Coquille and the South slough, and are separated by the Westport and Pulaski arches. The principal development has been in the Newport basin, so named from the Newport mine, which is the most important producer.

Baker County.

Near Greenhorn, the Snow Creek, Psyche and Diadem mines are all running again, having settled their June pay rolls. The Diadem is turning out good ore that is being treated at the Psyche mill.——The Big Johnny is having a mill test of its ore made at the Psyche mill.——The I. X. L. mill, at Greenhorn, is being put in shape to work ore from the Royal White. A mill test will also be made on ore from the Olive creek mines, near Greenhorn, for S. Tobin, who may put in a mill of his own.

Grant County.

New power drills are to be put in by the Portland M. & R. Co. at the Monumental mine at Granite. The shaft is down as far as it was intended to sink at this time. Drifts are to be started both ways and a raise made in line with shaft to the upper or mill level. There are fifteen men employed at the mine and this force will soon be doubled. Manager C J. Allen is taking a rest. S. P. Ross of Portland is in charge during his absence.

Josephine County.

A. B. Cousins, manager of the Galice Con. M. Co., operating on lower Rogue river, near Galice, states that his bedrock flume has been completed for 1800 feet from the Rogue river, with prospects of finishing dead work early this season. Washing gravel will begin a short distance beyond the present head of this work. They are cutting the flume down to 3 feet in bedrock and maintaining the width of 6 feet.

Lane County.

Blue River camp is affected by the low stage of water in its streams. The Lucky Boy has not been running full capacity lately, because of the shortage of water for the mill, and the smaller mills which have been put up the past season are also in trouble. As deep tunnels are driven, the flow of water in the basin is developing materially. At the Treasure, managed by C. H. Parks, the main tunnel has enough water for a fair sized plant, and the flow is increasing as the depth is attained. This shortage hindrance will be overcome in a year or so, and at present it is only the driest seasons that the trouble is experienced. Power, drawn from the McKenzie river, 6 miles away, never varies.

SOUTH DAKOTA.

Lawrence County.

Referring to the slimes plant to be put in by the Homestake Co. at Deadwood, C. W. Merrill reports that they have demonstrated experimentally on a practical scale that the 600 tons of slimes made daily by their mills and running from $0.50 to $1.00 per ton can be treated by cyanide at a profit.

UTAH.

Grand County.

It is reported that the McDonald Matte Furnace Co. of Toledo, Ohio, are to put up a 30-ton matte smelting furnace near Basin. C. W. Munson is manager.

Juab County.

The Raymond-Illinois, at Eureka, has been started up again with one shift, drifting on the 1500-foot level.——The May Day mine was recently closed temporarily on account of scarcity of water. Arrangements were made by Superintendent Eigan to secure water from the Uncle Sam M. Co., for which 800 feet of pipe had to be laid.

Piute County.

The capacity of the Annie Laurie mill at Kimberley is to be increased from 200 to 300 tons per day.

Salt Lake County.

The Shawmut Con. C. Co. has been organized to operate in Bingham canyon. The properties are on the north side of Carr Fork, in a large belt of lime. The management will extend the lower tunnel through the property, connecting upraises with the workings above. This will give from 800 to 1200 feet above the tunnel level. The property is equipped with a new mill designed by Manager Jackling, of the Utah C. Co., who estimates the cost of mining and concentrating the Shawmut ore at $7.29 per ton. The Shawmut Co. has a lease and option to buy the Sedalia copper mine, near Salida, Colo.

Manager H. S. Joseph of the Silver Shield M. Co. reports that a new 50-ton mill is to be built near the mouth of the main tunnel at Bingham.

Tooele County.

The Ophir Hill mill at Ophir is being enlarged by Manager E. W. Clark.

WASHINGTON.

E. W. Parker, in "Production of Coal for 1904," says that Washington's total production in 1904 was 3,137,681 short tons, valued at $5,120,931. The coal fields of Washington are confined to the western and central portions of the State. Four principal fields may be mentioned—the North Puget Sound field, including the coal mines of Skagit and Whatcom counties; the South Puget Sound field, containing the operations in Pierce and King counties; the Puget Sound basin, east of Seattle; the Roslyn field, in Kittitas county, on the eastern slope of the Cascade mountains, and the Southwestern field, embracing the counties of Lewis and Cowlitz. The coals of Washington range from lignite to bituminous coking coals and some natural coke has been observed. The bituminous coals of Washington are the only bituminous coking coals on the Pacific slope of the United States. The coking coals are found in the Wilkeson-Carbonado district, in the South Puget Sound field, in the Roslyn field and in the North Puget Sound field. The Wilkeson-Carbonado coal runs high in ash and is usually washed before coking. The lignite coals of Newcastle and Renton, in the South Puget Sound field, are generally of high grade and well suited for domestic use. Coal was first discovered in Washington in 1848, when a lignite of rather low grade was found in the Cowlitz valley. Four years later bituminous coal was discovered on Bellingham bay, Whatcom county, and the first mine in the State was opened on this bed. Shipments did not begin, however, until 1860. This mine was operated continuously from 1860 until 1878, when, because of a fire caused by spontaneous combustion, the workings were abandoned and they have not since been reopened. Shipments were not resumed from any of the mines in the northern district until thirteen years later—in 1891. Coal was discovered in King county in 1859, and mining began near the present Issaquah in 1862. Shipments to San Francisco began in 1871, since which time Washington mines have been an important source of coal supply to the San Francisco market. About the same time the Talbot and Renton mines, whicd are in King county, began shipping, and rail connection between the Renton mines and Seattle was obtained in 1877. Production in the Green river field, also in King county, began between 1880 and 1885, and the Pierce county fields, which had been opened up in 1875 and afterwards abandoned, again began shipping about the same time. The Roslyn mines, on the east side of the Cascade Range, were opened in the first half of the same decade. The Bellingham Bay mines, in the first year of their recorded production—1860—shipped out 5374 tons. In 1903, the year of maximum production, Washington's output of coal was 3,193,273 tons.

Snohomish County.

C. H. Packard of the Packard M. Co. of Monte Cristo reports that the new compressor plant has been put in and is doing satisfactory work.

Stevens County.

The Last Chance mine has resumed ore shipments to the Joplin, Mo., lead smelter and will ship regularly for several months. David Baker, superintendent of the mine, has made arrangements to have the ore hauled in wagons 8 miles to Northport.

Whatcom County.

A. W. Hawks, E. Blackman, Alonzo Low and W. Whitfield of Snohomish and W. Brown of Sylvana are at the Bonito G. M. Co.'s property in the Slate Creek district. The mines are 60 miles by trail from Bellingham and 50 miles from Brewster. Hawks, Blackman and Low will remain indefinitely and take charge of the work. Hawks, the business manager, intends to double the force in the mine and mill.

WYOMING.

Carbon County.

(Special Correspondence).—Encampment is a town of 1500 people, built up in the last five years, founded and supported principally by the Penn-Wyoming Co. and its antecedents. At the reduction works 150 men are employed. There are 30,000 pounds of copper at the smelter. At the reduction works one furnace is running night and day. They are also rebuilding a larger furnace, which is almost completed. By the system of smelting and concentrating which the Penn-Wyoming Co. employs, 90% of the copper is extracted from the ore. The Australian jig saves 80% of the ore and has a daily capacity of 800 tons of ore. Together with two 48-inch Griffith mills, twenty-four Wilfley tables and twelve Frue vanners, another 10% is saved. There is plenty of limestone in the vicinity. The company owns their own machine shop, foundry, blacksmith shop, harness shop, carpenter shop and electric lighting plant, supplying light for lighting the town as well as for their own use at the reduction works, and their own water power. The entire plant is run by water power furnished by water from a 4-foot main from a dam 4 miles above the works. The 16 miles of Leschen tramway from the mine to the smelter cost $385,000, and has a carrying capacity of about 1000 tons a day. The tramway carries 800 buckets 100 feet apart, averaging 700 pounds to the bucket. Three-fourths cord of wood furnishes power to run this tramway for one day. Considerable freight is carried over this tramway to mining companies in the immediate vicinity, netting the Penn-Wyoming Co. $1 per cwt. The cost of transporting ore over this tramway from the mine to the smelter, a distance of 16 miles, is 30 cents a ton, compared with $14 a ton when hauled by wagon. The mine of the Penn-Wyoming C. Co. employs about 100 men. The plant comprises three 80 H. P. boilers; one compressor, large enough to operate twenty-five drills; one engine, which runs the compressor, furnishing power to handle the cars for the mine; one 300-light dynamo direct connected to a 35 H. P. engine, to give light to the mine and surrounding buildings. A winze has been sunk from the lower level to a distance of 150 feet, showing ore bodies to that depth. All of the ore in the mine is handled by gravity and compressed air, thus reducing the cost to a minimum. The cost of producing the copper, including hauling to the railway at Walcott, is stated to be 6½ cents per pound.

Encampment, Aug. 17.

The Battle Lake Tunnel Site M. Co., owners of the Doane-Rambler mine at Rambler, will construct a 500-ton concentrating plant at the Doane-Rambler mine. A dam is to be constructed at the mouth of Battle lake by which it is proposed to raise the waters of that body 18 feet. The lake is surrounded on three sides by steep cliffs and the construction of the dam will create an immense body of water, furnishing an inexhaustible water power for the operation of the mine. Work will be in charge of H. F. Brown.

FOREIGN.

CANADA.

The Dominion government has appropriated $15,000 for making experiments with the electric process of smelting ores and manufacturing steel at Sault Ste. Marie, and the Con. Lake Superior Power Co. will furnish a building and dynamo capable of supplying 400 electric H. P. for four months free of charge. All kinds of ores will be experimented with. Great possibilities for Canada underlie the inauguration of a cheaper process for manufacturing pig iron and steel than is now in use. Ontario is dotted with ore bodies, the development of which is at present prevented by lack of cheap fuel. There is coal in the eastern and western parts of Canada, but the cost of conveying it to points where coke is needed for smelting purposes is prohibitive. On the other hand, there are a great many water powers throughout the provinces of Ontario and Quebec where electricity can be developed and utilized.

Ontario.

The Bruce copper mine has been purchased by the Lancaster syndicate of London, England, which has formed the Copper Mine & Smelting Co. with a capital of $1,000,000. The Bruce property is on Georgian bay, Algoma, and covers 12,840 acres. The ores are mainly chalcopyrite in quartz gangue, occurring in several parallel veins traversing diabase.

BRITISH COLUMBIA.

Boundary District.

(Special Correspondence).—At the 40-stamp Nickel Plate mill at Hedley sixty stamps are to be added by Superintendent M. K. Rogers. There are sixteen vanners in the concentrating room, to which eight are to be added, in addition to those for the new stamps.

Hedley, Aug. 18.

On the summit of Hardy mountain, 2500 feet above Grand Forks, at the American Eagle property the owners will build a tramway down the steep incline to haul ore for treatment at the Granby smelter. The mine is owned by John Holmes.——On the Betts and Hesperus mines on Hardy mountain, 4 miles from Grand Forks, a tunnel has been driven 600 feet. It has been decided by the management to add another machine drill.

At the Helen mine, on the east side of Boundary creek, near Greenwood, a new boiler, hoist and drills have been put in. A new two-compartment shaft is being sunk.——A new compressor has been put in at the Providence mine at Greenwood. Ore is being shipped regularly.

Figures for the first month of the second half of 1905 show that the ore tonnage of Boundary mines for July was somewhat in excess of the output for June. The total for seven months of 1905 shows that 527,874 tons have been shipped from the district mines so far this year. For July the following are the figures from the several mines: Granby, 54,320 tons; Mother Lode, 13,532; Mountain Rose, 330; Oro Denoro, 198; Emma, 1096; Providence, 60; E. P. U., 50; Last Chance, 20; miscellaneous, 75. July total, 69,681 tons.

East Kootenay District.

The Crow's Nest Pass Coal Co.'s employes have decided to stand out until the company pays the rates agreed to under the written agreement entered into last spring between the company and its employes. The men are all out. The present conditions at the Crow's Nest collieries will have an important and possibly serious effect on the camp if the strike is maintained for a considerable period. The Crow's Nest Pass Coal Co. has a monopoly of the fuel supply of the mines and smelters of southeastern British Columbia, including the Northport smelter. The Trail smelter is well supplied with coke, but the conditions at Northport, where the smelter is being operated at one-third its capacity, makes the situation rather serious for the Le Roi. The mines can get coal from Lethbridge, Roslyn and western Washington, but there is no coke available except from Coleman, in the Northwest Territory, and Comox, on Vancouver island.

Nelson District.

It is reported that work is to be started on a concentrator at the Molly Gibson mine, on Kokonee creek, which has been under development for the past two years, after a long shutdown, the company having repaired the tramway and mine buildings, which had been destroyed by a snowslide.

W. R. Ingalls, of New York, will head an expedition which will leave shortly to investigate the zinc deposits in British Columbia. The investigating party will meet in Nelson, B. C., about September 1. Philip

Argal, of Denver, will assist him. The points to be determined by the expert are as follows: (1) Examination of the present development of mines and approximate determination of tonnage of ore immediately available; occurrence and character of the ore and future prospects, together with cost of mining; (2) examination of present methods of milling; (3) investigation of adaptability of ores to the new methods, concentrates, magnetic, electrostatic, etc.; (4) study of conditions affecting marketing of concentrates, including question of smelting in province or elsewhere in Canada; (5) investigation of the possibility of utilization of zinc ore with silver content.

Rossland District

The tonnage of ore shipped from and crushed at the Rossland mines for the week ending August 19 was as follows:

	Week.	Year.
Le Roi	2,050	77,806
Le Roi (milled)	210	1,140
Centre Star	2,040	62,190
War Eagle	1,200	44,210
Le Roi Two	300	4,972
Le Roi Two (milled)		6,030
Jumbo	200	6,420
Spitzee		4,539
Velvet-Portland		1,977
Gopher	60	120
Homestake		30
Lily May		90
Inland Empire		30
Cascade Bonanza		30
White Bear		1,100
White Bear (milled)		2,920
Totals	6,120	213 613

The experimental concentrating mill of the Le Roi M. Co., at Rossland, has been closed down pending the installation of additional machinery. J. M. Astley is manager of the Le Roi.

Slocan District.

The remodeled concentrator at the Jackson mines, on Jackson creek, 5 miles from Whitewater, is turning out fifteen tons of zinc concentrates and two tons of lead concentrates daily. The auxiliary steam plant is to be started because of water shortage.——The Bell mine, adjoining the Jackson, has been sold to parties represented by John Keen, who will start development.

Vancouver Island.

(Special Correspondence). — During July the Tyee smelter ran eleven days and smelted 1793 tons of Tyee ore, giving a return, after deduction of freight and refining charges, of $31,472.

Duncans Station, Aug. 14.

MEXICO.

Chihuahua.

The Material Metal Co., controlled by the National Metal Co., is building a metal refinery at Nonoalco, in the Federal district, to handle high-grade ores, gold and silver bullion, sulphides, cyanide precipitates, etc. H. P. Lewis, general manager of the National Metal Co., with headquarters in Mexico City, is quoted as saying the plant will be in operation in sixty days. E. C. Doney, formerly in charge of the DeLamar Copper Works, Chrome, N. J., has been appointed superintendent of the new refinery.

Guanajuato.

It is announced in New York that the American Furnace & Securities Co. of New York has made the last payment on the purchase price, amounting to $2,500,000, to the Casa Rul M. Co. for its dumps and properties at Guanajuato. A fund of $400,000 gold has been set apart for mill construction and development work, from which reduction mills and cyanide plant have been purchased and are now on the ground at Guanajuato. These, with the pipe lines, buildings and tramways, are expected to be in readiness for operation by Jan. 1.

Guerrero.

(Special Correspondence).—The Rio del Oro Exploration Co. have commenced operations on their mineral concession of 300 square kilometers along the course of the Rio del Oro. Wm. Niven, the general manager, is directing the work of testing the large gravel deposits by sinking prospect pits to bedrock from 10 to 40 feet deep, at a cost of 30 cents Mex. per foot. The pay gravel averages from 3 to 6 feet and runs from 40 cents to $1 per cubic yard. The ground near the town of Placeres del Oro, in the valley of Potambo, shows the best values and is remarkably free from boulders. Water is abundant and the conditions quite favorable for dredging at some points.

The new gold district of Los Pozos, near the line of Michoacan, and only some 12 leagues from the Pacific coast, is attracting considerable attention at present. W. J. Neale and E. Nolte have returned after a month's trip to the region. They found the property guarded by soldiers, as some of the buscones had been carrying off the free gold ore which crops on the surface. After presenting their permit from the Mexican Government they made a thorough examination of the Antioquia mine. The chief feature of this property is the cropping of ore 45 metres long 12 metres wide and 8 metres high, which has been named the Bonanza Block. It is a mass of white quartz. Arrangements are being made to develop this valuable deposit. S. L. Butler has denounced some adjoining claims under the name of Los Pozos.

Placeres del Oro, Aug. 9.

Tamaulipas.

The Mexican Petroleum Co. is to begin drilling for oil again at Ebano. The drilling was stopped several months ago because no market could be found for the oil; but now that the Mexican Central and other railroads have made contracts for fuel oil for use in locomotives, it is thought that the petroleum company sees a market for its product. The drilling is to be commenced Oct. 1.

Zacatecas.

It is reported that R. S. Towne has closed down his mines in the Sombrerete district, thus throwing 5000 men out of employment. The 200 ore wagons, used to haul the ore from the mines to the Mexican Central to Fresnillo and Gutierres station, have been sold to mining companies in the State of Coahuila. Towne is said to have become disgusted with the Mexican Central for not building a railroad to that portion of the Sombrerete district and closed down to force the building of the branch road. The Central has had a concession for a road from Fresnillo through the Sombrerete district since 1899 and recently got the federal government to renew it at a cost of $10,500. The Towne interests own the San Luis Potosi smelter, the railroad to Sierra Mojada and other mines.

Books Received.

The United States Geological Survey has issued a second edition of J. E. Spurr's "Descriptive Geology of Nevada South of the Fortieth Parallel and Adjacent Portions of California," Bulletin 208.

In the series of reports of progress of stream measurements during 1904, the United States Geological Survey has issued Bulletin No. 125 on the "Hudson, Passaic, Raritan and Delaware River Drainages," and No. 130 on "Hudson Bay, Minnesota, Wapsipinicon, Iowa, Des Moines and Missouri River Drainages."

As an extract from the "Mineral Resources of the United States for 1904," the United States Geological Survey has issued "The Production of Coal in 1904," by Ed. W. Parker. The total coal production of 1904 was 352,310,427 short tons, with a spot value of $444,816,288, a decrease from 1903 of 5,045,989 short tons.

"Le District Aurifere de Cripple Creek et ses Recents Developpements dans la Zone Profunde" is the title of an article published by Etienne A. Ritter in the Annales des Mines and printed separately in pamphlet form. This is the first technical description of the Cripple Creek district published in the French language.

Professional Paper No. 38 of the United States Geological Survey, "Economic Geology of the Bingham Mining District, Utah," by J. M. Boutwell, with "A Section of Areal Geology" by Arthur Keith and an "Introduction on General Geology" by S. F. Emmons. This forms a comprehensive and masterly treatise on the geology of the region described.

In Bulletin No. 257 of the United States Geological Survey, T. W. Stanton and J. B. Hatcher describe the "Geology and Paleontology of the Judith River Beds" of northern Montana, with a chapter on the fossil plants, by F. H. Knowlton. The conclusion is reached that the Judith river beds are older than the Laramie and identical with the Belly river beds of Canada.

The excellent work of the United States Geological Survey in Alaska will undoubtedly do much to open up the country and make the outside world acquainted with the true conditions there. In Bulletin No. 251, L. M. Prindle describes "The Gold Placers of the Forty-Mile Birch Creek and Fairbanks Regions, Alaska," and in No. 247, F. H. Moffit writes of "The Fairhaven Gold Placers, Seward Peninsula, Alaska." These give the geography, geology and practical mining conditions of the district.

Commercial Paragraphs.

THE new briquetting plant of the Western Fuel Co. of San Francisco, Cal., is working steadily. Most of the output is for Spreckels Co.'s tug boats, and will be used soon also on the Pacific Mail liners.

THE Crocker-Wheeler Co. is in receipt of an order for a 200 K. V. A., three-phase, 60 cycle, engine type alternating current generator for the Ivorydale, Ohio, lighting and power plant of the Proctor & Gamble Co., a duplicate of the first Crocker-Wheeler alternator ever built, which was installed ten months ago in the Atlanta plant of the Proctor & Gamble Co.

THE Ottumwa Iron Works, Ottumwa, Iowa, report recent shipments of two carloads of mining machinery to Ocotlan, Mexico, and one sectionalized double hoisting engine to a gold mine in northern Mexico; two carloads of mine machinery to Littleton, Ill., one carload to Crecus, N. M., and one carload to Butte, Mont. The Ottumwa Iron Works further report contracts for two carloads to Robard, Ky.; one large double Corliss cylinder, 18x36 inches, with double independent friction drums, for a copper mine at Bisbee, Ariz.; two carloads of haulage engines for a concrete stone company of Chicago, Ill., and one carload for northern Idaho. The company will enlarge its business and put new lines on the market.

THE Wood Drill Works, Paterson, N. J., writes: "The greatest engineering feat of its kind ever known in the world was completed at ten minutes after four Saturday afternoon, July 22, 1905, at Henderson's Point, at the end of Seavey's island in Portsmouth harbor. Fifty tons of dynamite was exploded to blow up the rim of the point. The ground was broken August, 1902, and for three years Wood drills were working ceaselessly night and day drilling holes for excavating the rock at that point. During that period of time over 500,000 tons of rock was blasted and cleared away, nearly all of it below high water mark. The point has always been a manace to navigation for years and the Government finally decided that Henderson's Point should be no more. The river is now 400 feet wider at its narrowest point and 35 feet deep at low water. The contract price for the work was $749,000."

THE Calumet & Arizona M. Co. of Bisbee, Ariz., is installing a Sullivan Corliss cross-compound steam two-stage air compressor, with a total piston displacement of 3660 cubic feet, which, on account of the altitude at which the compressor operates, is figured to be equivalent to an actual delivered capacity of 2700 cubic feet of free air per minute, against a terminal pressure of 100 pounds per square inch while running at 83 revolutions per minute. This machine is expected to attain a high efficiency, being designed to run condensing, and to operate when carrying its most economical load on 15.2 pounds dry steam per 1 H. P. per hour. The steam cylinders are 17 inches and 34 inches and air cylinders 20 inches and 34 inches in diameter, with a common stroke of 42 inches. Rolling inlet valves, controlled by independent eccentrics, are used on both the high and low pressure air cylinders. Rolling discharge valves are also used on the low pressure air cylinder. In addition to these a number of automatic poppet discharge valves are used on the same cylinder. The high pressure air cylinder is equipped with a full set of removable automatic poppet discharge valves, which act in a direction parallel with the steam piston rod. An interesting feature is the automatic oiling system, which lubricates all the working parts regularly and without the attention of the engineer. The machine will be used for operating rock drills and other pneumatic tools about the mines. The company already has three Class WB-2 Sullivan straight line compressors, giving a total air supply of about 5700 cubic feet per minute.

Personal.

W. H. BREVORT of New York City is at San Francisco, Cal.

FRANK EARLE is consulting engineer Azurite M. Co., Dillon, Wyo.

ROBERT MAY has charge Banner M. Co., near Silver City, Idaho.

M. T. CHESTNUT of Webster Groves, Mo., is in Silverton, Colo.

ROBT. W. DAVIS, JR., is manager Old Hundred mine, Silverton, Colo.

D. R. REED, Ouray, Colo., has returned there from California and Nevada.

W. C. GREENE has left San Francisco, Cal., for Cananea, Sonora, Mexico.

H. A. MOORE of Idaho Springs, Colo., is developing a coal mine at Bellingham, Wash.

ALFRED BRILE has been engaged as superintendent Anchoria mine, near Dillon, Wyo.

W. C. THOMAS has returned to the Montreal & Boston Co.'s property at Rossland, B. C.

J. L. HARPER, manager Belcher M. Co., Republic, Wash., has returned from a trip East.

HOWELL HINDS of Cleveland, Ohio, is in Silverton, Colo., looking after his mining interests.

H. H. NICHOLSON, manager Standard Con. mine, Sumpter, Or., has returned to Denver, Colo.

L. MAURICE COCKERELL is now manager Mezquital Gold Mines, Mezquital del Oro, Zacatecas, Mexico.

HERBERT HAAS is at the Kamloops Mines, Ltd., smelter at Kamloops, B. C., on professional business.

GORDON HARDY, formerly manager Dolores M. Co., Chihuahua, Mexico, has resigned and gone to Japan.

SAMUEL NEWHOUSE is attending the directors' meeting of the Montreal & Boston M. Co., at Nelson, B. C.

F. H. JOHNSTON has succeeded G. W. Root as superintendent New York-Grass Valley mine at Grass Valley, Cal.

W. A. FRAZER has resumed his work as superintendent Rigby reduction plant at Mayer, Yavapai county, Ariz.

LEONARD D. SIVYER, a mining engineer and geologist of Los Angeles, Cal., is at Mayer, Ariz., on professional business.

EDWIN FERNALD of Detroit, Mich., has been appointed manager New York-Grass Valley mine at Grass Valley, Cal.

JOHN LAWLER, owner of the Hillside mine, west of Prescott, Ariz., has been in San Francisco and at the Portland Exposition.

W. H. ROELSMA has resigned from the Condor Water & Power Co. to take the management of the Alice mine, near Gold Hill, Oregon.

G. W. ROOT has resigned as superintendent New York-Grass Valley mine at Grass Valley, Cal., to devote his time to private interests.

J. T. CAVE, president Coast Line Copper Co., has returned to Pasadena, Cal., from a visit to the company's mines in Sonora, Mexico.

E. G. DEWALD is now the Pacific coast representative Platt Iron Works, Dayton, Ohio, with headquarters at 11-13 First St., San Francisco, Cal.

R. P. FRANCK, formerly of Benson, Arizona, has been appointed mining engineer for La Cia Minera del Picacho at Boacoachi, Sonora, Mexico.

RICHARD B. STANFORD has resigned as manager Ranch mine, Columbia, Cal., and goes as manager Siempre Viva mines, Nicaragua, C. A.

W. J. CURTIS has had charge of the work of the Keystone Copper Co., near Tapalpa, Jalisco, Mexico, during Manager Theo. Briedenbach's visit to Philadelphia.

WM. H. SHOCKLEY has been exploring copper deposits near Tokar, Sudan, Africa, and on Sept. 1 goes reconnoitering a gold dredging proposition in the Urals.

R. B. LAMB, superintendent Penn-Wyoming C. Co.'s concentrator at Encampment, Wyo., who has been seriously ill for a month past, has recovered sufficiently to resume his duties at the mill.

A. S. ADDITON has returned to San Francisco, Cal., from Boston and New York, where he went on business connected with the McKeen mine of the Helena G. M. Co., near Callahans, Siskiyou county, Cal., and which he recently examined.

Trade Treatises.

Circular No. 1108 of the Westinghouse Electric & Manufacturing Co. of Pittsburg, Pa., describes Westinghouse regulating and reversing controllers for alternating and direct current motors.

Crane Co. of Chicago, Ill., have issued a valuable treatise on "Flanged Pipe Joints." It describes joints used for various temperatures and pressures in attaching flanges to wrought pipe, including screwed, lap, weld, rolled, shrunk and riveted joints.

Bulletin No. 60, "Small Motors," from the Crocker-Wheeler Co., Ampere, N. J., illustrates one of their specialties, motors for small power service. On page 13 is technical data intended to be valuable to users of electric motors and generators of any make.

Latest Market Reports.

SAN FRANCISCO, August 25, 1905.

METALS.

SILVER.—Per oz., Troy: London, 28⅜d (standard ounce, 925 fine); New York, bar silver, 61½c, refined (1000 fine); San Francisco, 61½c; Mexican dollars, 47c, San Francisco; 46¾c, New York.

COPPER.—New York: Standard, $16.00; Lake, 1 to 3 casks, $16.00@16.25; Electrolytic, 1 to 3 casks, $16.00; Casting, 1 to 3 casks, $15.50 @ 15.87½. San Francisco: $16.50. Mill copper plates, $17.50; bars, 18@24c. London: £70 15s spot per ton.

The copper market remains firm, with a slightly increased price for the several grades of metal—Lake, electrolytic and casting. The demand appears to wholly absorb the output, and any event which may in any way suspend or retard the present output will undoubtedly result in an increase in price of the metal. While certain large dealers in the metal may be able to manipulate the market, the present healthy condition of the copper mining industry, and of the industries of the country, point to no lower price than at present quoted for some time to come. The visible supply on August 1, as reported by James Lewis & Son of Liverpool, was 17,411 tons, nearly 1000 tons less than the first of the previous month.

Following are the figures of the German consumption of copper for the months from January to June, 1905, as compared with the same period of time for 1904 and 1903:

	1905.	1904.	1903.
Imports, tons	52,886	56,316	43,688
Exports, tons	6,299	4,063	5,380
Consumption, tons	46,587	52,253	38,308

Out of the above, 44,656 tons were imported from the United States.

LEAD.—New York, $4.70; Salt Lake City, $3.50; St. Louis, $4.52½; San Francisco, $3.70, carload lots; 4¼c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5¾c; pig, $4.85. London: £14 ℔ long ton.

SPELTER.—New York, $5.75; St. Louis, $5.65; London, £24 17s 6d ℔ ton; San Francisco, ton lots, 6¾c; 100-lb lots, 7c.

TIN.—New York, pig, $33.15@33.50; San Francisco, ton lots, 34c; 500 lbs., 35c; 200 lbs., 35½c; less, 35½c; bar tin, ℔ lb., 35@37½c. London, £145.

PLATINUM.—San Francisco, crude, $18.50 ℔ oz.; New York, ingot, $20.50 ℔ Troy oz. Platinum ware, 75@$1.00 ℔ gram.

QUICKSILVER.—New York, $41.00@$41.50, large lots; London, £7 7s 6d; San Francisco, local, $38.50@39.00 ℔ flask of 75 lbs.; Denver, $42.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 32½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 23.00c; San Francisco, Plumbers', 100-lb. lots, 19.00c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb, .04c.

NICKEL.—New York, 55@60c ℔ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 33@37c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c ℔ lb.; 100 lbs., 35c; 1000 lbs. 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c. Pittsburg.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $14.85; gray forge, $16.00; San Francisco, bar, 3c ℔ lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, $21.00@$21.00; open hearth billets, $23.00@$23.00; San Francisco, bar, 7c to 12c ℔ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 7¼c; less than 500 lbs., per lb., 8c; in 25-lb. tin pails, ½c ℔ lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LIME.—Santa Cruz, $1.25 country, $1.25 city ℔ bbl.

CEMENT.—Imported, $2.15@2.65 ℔ bbl.; California, carload lots, $1.90 f. o. b. at works; small lots, $2.20 ℔ bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

LUMBER.—(Retail): Pine, ordinary sizes, $24.00@5.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50@5.00; pickets, $21.00;shingles, $2.50 for No. 1, and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00@35.00.

NAILS.—This week the basic prices are: Wire, $2.77; Cut, $3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d, Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4d and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 13½c; Hallett's, 14½c; San Francisco, 1000-lb. lots, 14c; 300@500-lbs. 12c; 100-lb. lots, 13c.

BISMUTH.—Subnitrate, ℔ lb., $2.10.

BONE ASH.—Extra No. 1, 5@6c ℔ lb; No. 1, 4@5c.

BORAX.—Concentrated, 7@8c ℔ lb; powdered, 9@10c; fused, 25@30c; crystal, 7c.

CANDLES.—Spear Brand, 16 oz. adamantine, 40s., 11c ℔ set; 14 oz. adamantine, 40s., 10c; 12 oz. adamantine, 40s, 9c; 10 oz. adamantine, 40s, 8c; 16 oz. stearic, 40s, 12¾c ℔ set; 14 oz. stearic, 40s, 11½; 12 oz. stearic, 40s, 10½c; 10 oz. stearic, 40s, 9½c. 100-case lots and over, ½c less. Not less than 50-case lots, ¼c less. Boxes of 20s, price ½c advance.

CAPS.—3x, $5.50@6 per 1000; 4x, $6.50@7; 5x, $8@8.50; Lion, $9@9.50, in lots not less than 1000.

CHEMICALS.—Cyanide of potassium, 98%–99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c ℔ lb.; caustic soda, in drums, 3@3½c ℔ lb.; Cal. s. soda, bbls., $1.10@1.20 ℔ 100 lbs.; sks., 90c@$1.00; chlorate of potash, 12@13c; nitrate of potash, 6½@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2½@2½c; flour sulphur, French, 2¾@—c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 5½@5¾c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66° B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

CHROMIUM.—90% and over, ℔ lb., 80c.

COAL.—San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lot, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $8.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13.00 in sacks; Sunnyside, $8.50, long ton.

FIRE BRICK.—Domestic, carloads ℔ 1000, f. o. b., factory square, $25.00; soap and split, $22.50; arch and wedge, $27.50; skewback, $30.00; circle, $32.00.

FIRE CLAY.—Domestic, ℔ ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, $8.50.

FUSE.—Triple tape, $4.00 per 1000 feet; double tape, $3.50; single tape, $3.10; Hemp, $2.75; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 and up.

LITHARGE.—Pure, in 25-lb. bags, 9½@10½c ℔ lb.

MAGNESIUM.—Pure, N. Y., $1.60.

MANGANESE.—Black oxide, ℔ lb., 2¾@4c.

MERCURY.—Bichloride, ℔ lb., 77c.

MOLYBDENUM.—Best, $2.75 ℔ lb.

OILS.—Linseed, boiled, bbl., 64c; cs., 69c; raw, bbl., 62c; cs., 67c; Lucol oil, boiled, bbl., 56c; cs., 61c; raw, bbl., 54c; cs., 59c. Kerosene—Pearl, per gal., 17½c; Astral, 17½c; Star, 17½c; Extra Star, 20½c; Eocene, 19½c; Elaine, 26c; Water White, in bulk, 11c; Mineral Seal, iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 14½c, do., cs., 21c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 12½c; do., in cs., 19c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 68c; Bleached, do., 57c; Whale Oil, cs., 52@67c.

PHOSPHORUS.—American, ℔ lb., 70c.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1**, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2**, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

RED LEAD.—500 lbs. and over at one purchase, ℔ lb. 7¾c; less than 500 lbs., 8c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 55c.

SODIUM.—Metal, ℔ lb., $1.

TUNGSTEN.—Best, ℔ lb., $1.25.

URANIUM.—Oxide, ℔ lb., $3.50.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR WEEK ENDING AUGUST 8, 1905.

796,696.—CLASP—F O. Brockhaus, Port Angeles, Wash.
796,888.—PACK SADDLE—C H. Baker, Republic, Wash.
796,805.—CENTERING FRAME—P. R. Burton, Bakersfield, Cal.
796,901.—SAW—H. Dool, Northfork, Cal.
796,711.—SHIRT—C. J. Ferguson, Pendleton, Or.
796,572.—LUMBER DRESSER—J. F. Finnegan, Igerna, Cal.
796,631.—JAR CLOSURE—F. O. Fischer, San Leandro, Cal.
796,905.—HOG CATCHER—D. P. Funk, Monroe, Wash.
796,636.—JOURNAL BOX—F. Gottfried, S. F.
796,909.—PUMP—E. A. Hardison, Bakersfield, Cal.
796,643.—TANK LUG—E. N. Harmon, Belvedere, Cal.
796,967.—THILL IRON—C. Heilrath, Sacramento, Cal.
796,645.—SQUARE—J. Herche, S. F.
796,971.—HEATER—Houze & Hurrie, Stockton, Cal.
796,727.—ELASTIC FLOOR—C. R. Hunt, Sacramento, Cal.
796,735.—FURNACE—F. Klein, San Jose, Cal.
796,521.—BARBER'S CHAIR—W. Lupton, Lodi, Cal.
796,590.—IRRIGATING APPARATUS—J. H. Martin, Riverside, Cal.
796,592.—HOE—H. Matthiesen, Livermore, Cal.
796,753.—TREATING ORES—J. B. Parks, Spokane, Wash.
796,754.—TREATING ORES—J. B. Parks, Spokane, Wash.
796,674.—FAUCET—E. A. Rider, Stockton, Cal.
796,677.—CAP FOR TUNING PINS—I. B. Rosencrantz, S. F.
796,538.—DRESSING FISH—E. A. Smith, Seattle, Wash
796,613.—TOBACCO PIPE—N. B. Stone, Outlook, Wash.
796,540.—METER—J. Sutherland, Seattle, Wash.
796,541.—HOIST—W. A. Tompkins, Portland, Or.
796,948.—FISHING ROD—J. B Tuttle, Claremont, Cal.
796,477.—THRESHER—R. V. Wallace, Alki, Wash.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS UNITED STATES and FOREIGN PATENT AGENCY, the following are worthy of special mention:

DISK PLOW ATTACHMENT.—No. 797,177. August 15, 1905. W. S. Cook, San Jose, Cal. The main object of this invention is to increase the tread of the plow so as to render the plows very steady in their operation and prevent undue oscillations and movements of the frame. The device consists of a plow beam or frame, a bracket adapted to be bolted to said frame, a horizontal journal box carried by the bracket, a crank axle having long and short arms each turnably fitted to the journal box, and a land wheel fitting and turnable upon either arm of the axle when the other is in the journal box. A lever is fulcrumed upon the journaled arm of the axle having its short arm bolted to the crank portion of the axle, and there is a segment concentric with the journal box having peripheral notches and a pawl carried by the long arm of the lever adapted to engage said notches

DUMP WAGON.—No. 797,164. August 15, 1905. R. E. H. Wurdisch, San Francisco, Cal This invention relates to a wheeled vehicle having a body adapted to carry loose material and connections by which said body may be so disposed as to discharge its load and to again be returned to its normal position. It consists of a main wheel frame, a supplemental frame hinged at the rear, a vehicle body freely movable upon said frames, a winding drum mechanism by which the supplemental frame is raised into an inclined position, means for allowing the body to move rearwardly on said frame to a dumping position and to return the body to its normal position, a tail gate hinged to the upper part of the body and a lever mechanism by which said gate is opened to discharge the contents.

SECTIONAL CENTERBOARD FOR VESSELS.—No. 797,146. August 15, 1905. Viggo L. Ogidinssen, San Francisco, Cal. The objects of this invention are to provide a centerboard which will not require the cutting in two of the vessel along the keel, as is now customary, and which weakens the vessel considerably; to avoid having the large heavy casings in the hold, as at present, and which add to the weight of the vessel and take up so much room as to be a continual detriment in loading and unloading; to add to the efficiency of the used surface of the centerboard to prevent a vessel making lee-way, (with ordinary centerboards only half of their surfaces is available for that purpose) and finally to distribute the strain from the centerboard more evenly over the vessel's keel and body. The various parts are adapted to produce the required result.

MINING SLUICE.—No. 797,168. August 15, 1905. Pierre Bouery, Weaverville, Cal. This invention is particularly applicable to such sluices as are employed to save valuable and precious metals, while allowing the rocks, boulders and heavy valueless material to escape. It consists in a sluice having bottom, sides and transversely disposed riffles, rails mounted thereon with connecting bolts, interspacing bolt protecting blocks, rails fixed along the sides of the sluice and resting upon the riffle rails and living blocks fixed to the sides of the sluice above said longitudinally disposed rails; and other details of construction.

Common Sense

teaches us that **RUBBER** against an article creates friction. In fact, we wear rubber soles—use rubber on steps, etc., to prevent slipping—to create friction.

Why do you use **ENGINE PACKING** with rubber on top—on the bottom—and in between—where it is rubbing against the rod all the time—creating excessive friction—loss in power—fuel—money?

No such mistake in

"EUREKA" PACKING.

The rubber is where it should be—embedded in flax—which takes the wear—the lubricants prevent friction.

Isn't it up to you to try **GENUINE "EUREKA,"** particularly as the price is one-half less?

JAS. L. ROBERTSON & SONS, 195 Fulton St., New York

A. D. COOK,

Manufacturer of Improved

Water and Oil Well Supplies.

Cook's Patent

TUBE WELL STRAINERS, STEAM PUMPS, WORKING BARRELS, PUMP RODS AND PUMP ROD JOINTS

A Specialty.

LAWRENCEBURG, INDIANA, U. S. A.

UNDOUBTEDLY the best results are secured where technically educated men are placed in charge of mining and metallurgical operations, provided the men are otherwise fitted for such positions. Some men go through the college course without giving their studies the necessary thought. They are superficial, and manage to get through in some way, but such men rarely make a success of their chosen profession. It is those who go into the university with one determination uppermost in mind — to make the most of the opportunities presented; to endeavor to understand and to make practical application of the knowledge thus gained. All cannot step from the graduation stage into the position of superintendent or manager. A few, by reason of personal influence of family or friends, may, but the majority find this impossible — nor is it best. There is a period of apprenticeship which must be first served to fit the student for the higher duties and responsibilities of life. There is much of detail to be learned which can only be accomplished by direct application and continued contact with the work, and with the men. There are menial jobs to be done, and one must do them if he is to become a competent judge of the performances of others. The college is but the preparatory school — the beginning of knowledge — not its ending.

The Question of Power for Mines.

A paramount question in the equipment of new mines is what kind of power shall be adopted. This question should be answered by the economic conditions presenting themselves at each particular mine. Undoubtedly the most satisfactory power is that developed by free water—that is a water power, or privilege, owned by the mine. Such a power, if constant in amount, is flexible, in that it may be applied to hoists, compressors, electric dynamos, to mills, and to every description of machinery requiring motive force. The compressed air or the electricity may be economically carried to considerable distances from the generating station and utilized in many ways, in operating drills, running hoists, and variously otherwise. True, steam may be applied in similar manner to all of these various uses, and so also may electricity, as a primary power, but electricity must either be bought from a distributing company or generated by the mine's own power plant. Steam requires a considerable outlay of capital and is a source of constant expense when operating. The water power plant may be far more expensive in first cost, but more economical in operation unless the water must be brought from a distributing company at such a price as to increase the cost. The power question should always be determined in the same manner as any other concerning mine equipment and operation —by careful consideration of all the features having a bearing upon economical result and a selection made accordingly. Occasionally a mine is seen equipped with both steam and water power plants, both of which are in operation at the same time. The conditions are unusual where this becomes necessary, but it is no uncommon thing to find mines equipped with water power plants, with steam as auxiliary, to be used in the event of failure from any cause of the water plant. The breaking of a reservoir, ditch, pipe line or flume may close down a mine for some time if no steam plant is available. Many mines have installed electric plants, buying power from distributing electric companies, but it is always wise to keep the steam or hydraulic plant in readiness in the event of the failure of the electric power. In some mining districts the electric companies have endeavored to entrench themselves the more strongly by buying up the pre-existing water companies and informing the operating mining companies, which have for years been buying water from the ditch companies, that "all the water is now required for the electric plant, and electric power must be substituted for water power." Where the change does not work an apparent disadvantage to the mining companies, there is seldom a serious objection to this change; but, in the event of the failure of electric power, the mines are closed down for a greater or less time until power can be again delivered to them. The right to a continued use of the original water under these circumstances is a matter for the courts to decide. Such irregularities are annoying, but they also occur with private as well as distributing companies. There are so many phases of the power problem, under ordinary circumstances, that the matter should receive very serious consideration and be investigated from every point before being definitely decided. Even when steam is decided upon, the various classes of fuel should be considered with reference to their relative value. In most cases there is a choice between wood, coal and petroleum, and also gasoline or distillate engines, as a means of power. Each must be fully inquired into, as well as the relative efficiency and cost per horse power month, of each of the sources of power available. The matter is not usually a difficult one to decide, but it requires some careful thought.

THE ending of the bitterly fought war in the Orient is likely to result in an expansion of the mining industry in the countries most affected, particularly in China and Korea, where there are known to be extensive undeveloped mineral resources. Japan, too, it is assured, will take immediate steps to enlarge the scope of the mining already being done and to apply the most approved American methods and machinery for the time being, at least. Just how far America and Americans will be benefited by the new regime is difficult to predict, as to Japan, but in both China and Korea, where there are already extensive American interests, additional concessions will be sought and new development undertaken. The mineral resources of the Celestial empire are varied and extensive, and the adoption of American methods, with the native cheap labor, will make propositions of unusually low grade available and profitable.

The Reward of Perseverance.

The success attending the efforts to successfully treat a constantly lower grade of slimes at the Homestake plant at Lead City, South Dakota, is an instance of perseverance and intelligent scientific experimentation rewarded. The Homestake ores are low grade, and the slimes created in the stamping of these ores are of infinitesimal fineness. These, after the several metallurgical operations through which they pass, still contain from 50 cents to $1 per ton in gold. These slimes it is now proposed to treat by a new process, as previously mentioned herein, and a new plant is to be built at Deadwood, where the slimes from all of the several mills of the Homestake Co. may be conducted by gravity, thus reducing the cost incident to the operation of two plants. C. W. Merrill has spent several years in the treatment of Homestake tailings by the cyanide process, and has succeeded in treating at a profit a constantly lower grade of material. It should not be understood that the Homestake tailings and slimes are constantly growing of less value with the passing of the years, but the percentage of extraction has been increased and the cost per ton of operating has been reduced from year to year, until this final result seems to have been accomplished. Whether still further improvements will be made beyond this latest achievement remains to be seen. All of the ores now being successfully treated by the cyanide process in its various modifications in the Black Hills gave much difficulty in the earlier days, but for most part these difficulties have been overcome and the most rebellious ores, with the exception of a single kind—the so-called unoxidized or blue telluride ores—now yield a high percentage of their values at relatively low cost. Chlorination, cyanidation and smelting have each been helpful in the solution of these vexing metallurgical problems. In the southern Black Hills, however, are still some rather annoying and perplexing metallurgical problems. In that region are some mines in which the gold is largely associated with arsenic, and it is these ores which have proven difficult of treatment. The Keystone, Holy Terror and Extreme mines each have had this sort of trouble, and were it not for the unusually high grade of these ores at the mines mentioned, they would probably have proven too unattractive to capital. The Holy Terror early in its history attracted attention by the high grade of its output. Nothing stimulates endeavor to overcome difficulties like abundant reward if success be attained, and the good grade of the base ores generally in the hills will continue to make them a subject for the attention of expert metallurgists until the several problems of their reduction have been solved.

ELSEWHERE appears a report of a lecture recently delivered at the Academy of Sciences in San Francisco, Cal., by a captain in the Corps of United States Engineers, a member of the California Debris Commission, a body that is vested with considerable power and grave responsibility. Seldom does this journal praise or censure, but it is only their just due to say that the members of the California State Debris Commission, from its inception in 1893 to the present hour, have shown a zeal and singleness of intelligent purpose that entitles them to the thanks and commendation of all whose interests are affected by their acts. The task assigned them from the start was wholly without precedent; the conditions were all new and untried, the appropriations inadequate, the expectations both sanguine and immediate. That progress has been slow, and at times unsatisfactory, is to have been expected. Even the ægis of United States authority is not always sufficient to immediately overcome such a stupendous problem as that given the United States engineers in California to solve. With the resources at their command, they have done much, and it is believed that with the experience gained, advance in the solution of the problem will be more rapid.

CONCENTRATES.

THE cost of operating a mine depends much on the character and size of the mine: much on the situation and not a little on the management.

FLUMES are sometimes built on a grade cut into the hillside like a narrow road, and the flume then covered with earth. This is done sometimes in cold countries to prevent freezing.

ASSESSMENT work may be done on a patented claim for the benefit of a contiguous unpatented claim, provided such work is actually a benefit to such jointly owned unpatented claims.

CONCRETE, properly made, cannot, after having firmly set, be picked down. It is as firm as rock and must be blasted. The proportions of materials used in mixing concrete vary, according to the purposes for which the concrete is to be used.

BELL CORDS should always be placed in the shaft within the reach of the men riding on the cage or skip. Nothing in the equipment of a mine requires more careful attention than the bell signal service, for on it the lives of the men depend.

A HEAVY iron gossan does not necessarily indicate a valuable deposit of copper ore below. There is usually, though not always, some indication of copper in the gossan if there be any below. This indication appears in the form of copper carbonates and oxides.

OF primary importance is the size of vein, value of the ore and the method of recovering the mineral, and the cost per ton of the entire operation of mining and treatment. These questions are usually of greater importance than the character of the ore deposit.

WHERE stamp stems cannot be readily driven out of the boss head by blows of the sledge on the wedge, small charges of dynamite may start the stem. This method is usually successful, but should be used with caution, as there is an element of danger in employing it.

THE relocator of an abandoned mine cannot claim the work performed nor improvements made by the former owner when applying for a patent. The new tenant must comply with all requirements of the law, the same as though the ground had never been located.

IF rock drills be tempered very high—straw color in very hard ground—they are likely to chip off at the corners, and sometimes, unless the temper be evenly drawn, the entire bit snaps off. A color between bronze and dark blue is rather better in the hardest ground.

IN Mexico, where it is believed that placers exist at considerable depth below the surface, and no surface discovery is possible, the law gives the miner one year in which he has the exclusive right to prospect his claim by shaft or otherwise, to make the necessary discovery.

THE depth of a gravel channel covered by soil, heavy deposits of gravel or by a lava cap, may usually be determined by boring. Information gained in this manner may save many thousands of dollars, which not infrequently results from running a tunnel too low, the depth of the channel being only guessed at.

LARGE BOULDERS in drift mines are often a source of much annoyance and expense. When directly in the way it is usually the better plan to work around them, though in main drifts and gangways they are sometimes blasted out, the result being a straight drift and uninterrupted grade. Often considerable gold is found to have lodged under boulders of large size.

MINING and milling of gold ore has been done in California, according to official report, for less than 50 cents per ton, at the Dalmatia mine, near Kelsey, El Dorado county. (See Tenth Annual Report of the State Mineralogist, pages 174–175.) Two miners did all the work in the mine under contract, at a cost of 7½ cents per ton. Transportation and milling brought the cost up to about 50 cents per ton.

SUSPENDED earthy slimes may be prevented from entering the zinc precipitation boxes of cyanide plants by placing a filter of cocoanut matting in layers in the head box. The particles of precipitate which may be suspended in the water flowing through the boxes, which are disturbed from time to time through various causes, may be caught on a similar filter placed after the last zinc compartment.

WHERE a crankpin was tightly held by reason of having been shrunk in, the pin was removed, when it became necessary, by drilling a hole through the center of the pin from end to end, tapped each end to fit a ¾-inch pipe thread, and screwing a piece of pipe in the same with cold-water hose attached to one end of the pipe. After heating the crank and pin to a cherry red by means of a portable forge, the water was turned on, cooling the pin, which shrunk sooner than the more massive crank, and the pin was withdrawn by the attached pipe.

INVESTIGATION of the sources of the diamonds found in North Carolina is to be made. Diamonds are found in the glacial drift of Wisconsin and in some of the ancient river channels of California, but the source of any diamonds found in the United States has never as yet been discovered. A species of flexible sandstone, said to accompany the diamonds of Brazil, S. A., is also found in some of California's ancient rivers.

A WATER SUPPLY of fifty gallons per minute is an insufficient quantity to operate an overshot wheel of large diameter, and the power derivable from this quantity of water on a small wheel is not commercially valuable. It would be more economical to employ some form of gas engine if a larger supply of water is not available. Overshot wheels are not advisable with a constant supply of less than 15 cubic feet per second.

IT will pay in almost every case to pump water to a quartz mill, rather than transport the ore a long distance to the water. In California there are several mines where the water is pumped from 1 to 14 miles and raised from 100 to over 500 feet. The cost varies with the size of the plant, etc., but is seldom over 20 cents per ton of ore treated. The water may, in most cases, be settled after passing the mill, and pumped back for reuse.

TOO MUCH CARE cannot be given the locating of a mining claim. The locator should endeavor to comply as fully as possible with the requirements of the law—all this for protective purposes—for if the claim prove to be rich a careless disregard of the legal requirements may result in the loss of the claim to the discoverer, or serious and expensive legal complications. The laws are simple and easily understood, and should be followed to the letter.

GOLD ore which does not show free gold upon panning may still yield a fair percentage of its value to amalgamation. The fact that the gold is extremely fine does not always render the ore refractory nor make it incapable of amalgamation. It will probably be necessary to crush ore of this character, through a fine screen, in order to free the particles of gold. Such ore may also prove amenable to the cyanide process, if there are no base materials present, which prevent successful treatment by that method.

COPPER in solution in the water flowing from copper mines can be precipitated by passing the water through sluice boxes having a low grade and filled with scrap iron, tin scrap, etc., the copper displacing the iron. The tin has no effect on the copper, and small flakes of the tin may sometimes be seen in the precipitates. The acidulated water decomposes the thin sheet of iron which lies between the film of tin on either side of it, and the tin scales off, usually in flakes so small as to be unobserved. Occasionally, where tin cans have been used as a precipitating agent, the gummy substance or varnish with which the can has been covered, causes good sized patches of the tin to adhere, when the tin may be readily seen.

IT is a common feature of large quartz veins to be divided into a series of floors by cracks, which extend from wall to wall, usually at right angles to the dip. The distance between the floors is variable in different veins and also in the same vein. Near the surface these cracks are sometimes several inches wide, the space on the floors or between the blocks being filled or partly filled by granulated quartz, quartz crystals, clay, iron oxide and other minerals, and sometimes also gold. The reason for the separation (particularly noticeable in granite formation) is probably due to the decomposition of the granite, which has resulted in an increase in bulk, causing the vein to be drawn out and the several blocks thus separated.

QUICKSANDS, through which it became necessary to sink, have been hardened by injecting hydraulic cement into the bed of sand. This has been successfully accomplished by driving pipes into the quicksand at varying distances of 4 to 8 feet and attaching a pump to each alternate pipe, leaving the remaining pipes open. When pumping began, a circulation was established between all the pipes of the series. When sufficient sand had been removed, a cement grout was pumped in for some time and the open pipes were capped and the pumping continued, which forced the grout into the sand. The pipes were drawn a foot or more and the operation repeated. The cement sets, causing the ground to become hard enough to be mined out. Flows of water may also be retarded in ditch work or other excavations in wet materials. This scheme can only be operated under favorable conditions.

MUCH of the success of concentrating machines depends upon a proper distribution of the feed at the head of the belt or table. It does not pay to overload a concentrator nor to keep a certain class of the material at an intermediate point, where it neither passes over with the valuable material nor off at the lower end with the tailings. This class of material accumulates to the disadvantage of all the remainder of the pulp being treated. The fact that this middle product does occur proves conclusively the necessity of hydraulic classification before attempting to concentrate on machines of any kind. For the best work the pulp must be first classified, and then the feed and fresh water supply must be regulated and maintained at a stated rate, and the machines must run steadily at a given number of vibrations, for after once having been properly adjusted to given conditions, if these conditions, or any of them change, poor work is the immediate result.

A GOLDFIELD, NEV., MINER has offered the following ingenious theory to account for the rich accumulations of gold found in that district at and near the surface: "The ore occurs on the knolls and not in the depressions, which may be explained by the fact that the ores are more siliceous, and being harder, are better able to resist erosion than the normal rock, which being softer is eroded more rapidly, producing hollows. The soil and superficial rocks of the Goldfield region are impregnated with manganese, sodium chloride, calcium sulphate, fluorite, etc. The decomposition of the sulphides of the veins supplied sulphuric acid which, acting upon the sodium chloride in the presence of the black oxide of manganese, liberated chlorine, and being a solvent of gold, dissolved it, and reprecipitated the metal at favorable places, through the medium of surface waters, thus accounting for the remarkable instances of secondary enrichment found there."

CONTRACTS for shaft sinking, drifting and for other mining work are commonly undertaken by miners, and not infrequently to their advantage. The contractors never put up bonds to guarantee the fulfillment of the contract, for the reason that there are so many unknown conditions and possibilities that he cannot afford to assume the risk. Contracts of this character are not altogether one-sided in their operation. The miner may base his price on hard ground at the beginning of the contract and the ground may become softer or otherwise easier to work, which results in the contractor making more than he anticipated; but if the ground becomes so hard he cannot fulfill his contract without considerable loss, he usually gives up the job. Most contracts stipulate that 25% of the contract price on work completed shall be withheld until the completion of the entire contract; so if the miner throws up his contract he forfeits one-fourth of the amount of money he has earned.

THE selection of a mining method without an opportunity to examine the situation is not an easy matter, but in the case where the vein is described as being 8 feet wide between firm and fairly well-defined walls, with a dip of over 60°, it would seem that the proper method would be the driving of a heading about 15 feet high along the ore shoot, the full width of the vein. This should be substantially timbered with posts and cap sets, and heavy lagging of 6-inch poles laid on the caps. This will bring the floor of the stope within 6 to 7 feet of the back—a good working height for hand or machine drilling. Some shoveling may be saved and lagging protected by running this heading in two sections, the uppermost one several feet in advance; then, if the timbering be kept well up to the lower face, much of the rock blasted from the upper face will fall upon the lagging. Loading chutes should be provided every 30 feet along the length of the stope and unless good air is mechanically provided for the stope a raise should be run to the level above, and in the event of the ore shoot proving to be a long one—200 feet or more—it would be wise to have a raise at either end, and, if in excess of 300 feet, a raise at every 150 feet. When the workings have been arranged as suggested, stoping operations may begin by shooting the rock down upon the lagging, with lightly loaded holes at first, until the poles are protected from heavy blasting. The large rocks must be broken up to pass the chute doors, and only enough ore drawn away to make proper room for the men to work in the stopes without either cramping them for space or allowing the back to get too high for convenient work. A cribbed manhole should be carried up with the ore at one end, both ends, or at intermediate points, according to the length of the stope. The chutes require no cribs, provided no great amount of waste is shot down with the ore. As stoping progresses upward, only about one-third of the ore is drawn off. When approaching the level above the back may be shot down or left intact, according to requirements, and at the discretion of the superintendent. In this system no timber is required except that used in the sill floor sets and in the manways. The ore supports the walls, and as it is eventually drawn off, if any slabs fall or the walls collapse, no particular harm is done. The stope may be entered at any time, and, as the ore settles by reason of being drawn away below, any slabs of wall rock which appear threatening may be removed and broken up, or allowed to remain on the ore. When the accumulated waste of this description reaches the chute it may be rejected and either sent out of the mine, piled up in walls, or allowed to remain in the stopes. In some instances even the timbers may be removed and reused, if still in good condition. In some veins it might be advisable to put up raises every 30 feet along the drift, for a height of 10 feet, placing the chutes directly below the raises. The stope may then be opened out about 10 feet above the back of the gangway, and the work of stoping carried on as described above. This will leave several sections 10 feet thick and the width of the vein to remove after the stope is all mined out, and will save the cost of timbers, framing and placing the same, and also the cost of considerable shoveling at the start.

"Control of Hydraulic Mining Debris in California by the Federal Government."*

Announcement that an address on the above subject would be given by Capt. Wm. W. Harts, U. S. Corps of Engineers, in the Academy of Science building, in San Francisco, Cal., on the evening of Aug. 21, filled the auditorium to hear one of the California Debris Commission give an authentic account of what had been done and what was proposed to do in the great work of such interest to the hydraulic miners of California since the inauguration of the project in 1893.

The lecture was an interesting one and worthy of the source. Seldom is so good an opportunity afforded to learn from a prominent U. S. engineer regarding the history and details of the work in the supervision of which he is engaged, and Capt. Harts' address is a notable contribution to the sum total of knowledge on this important subject.

The first portion of his lecture was devoted to a history of the mining debris problem in California, the situation that gave rise to the creation of a California Debris Commission, and the scope and intent of that body's powers. This was followed by a description of the mining region assigned to the control of the Commission, and estimates of the amount of detritus lodged in the streams, and the duties of the Commission under the federal law. Following this, in speaking of the manner of work done, Capt. Harts furnished considerable further data hitherto unpublished. In the matter of individual dams, he said that various kinds of dams had been tried—those of stone, of earth, brush and rock, log-crib filled with rock, and many others. After twelve years of experience, it has been found that the usual small mine, where impounding dams can be used, will need one of two general types—either log-crib dams or brush dams.

There are special cases, of course, where other kinds of dams are needed; but these two types are most common for the smaller mines, and printed specifications for these dams, with a cut explaining their construction, have been prepared by the Commission.

The log crib is the more common type. It consists of a cob-house crib, with the logs of which it is made notched and bolted together. It is filled with quarried rock and chinked against leakage. This type of dam is seldom built over 40 feet high, this being the limit of safety placed by the Commission for the usual case. These dams are very satisfactory for their purpose when well made. As long as they are kept wet they are practically permanent, and in those locations where the logs rot, due to being dry part of the time, the rock being well bedded in gravel will resist erosion long after the logs have failed to bind the dam together.

The brush dam is less used, as it is permitted usually only when the water flow over the dam is small, or when the river is diverted through a spillway at one end, and only when the slope of the canyon above is slight. These brush dams are not permitted over 20 feet in total height.

In this way the debris from hydraulic mining has been regulated so that very little is added now to the old supply. These restrictive measures have unfortunately been too much to permit the resumption of hydraulic mining on the large scale it formerly was accustomed to; but, on the other hand, they have permitted many mines to operate that otherwise would have to remain idle.

There is now mined nearly a million cubic yards each year which is stored in the canyons and ravines behind debris dams especially constructed for the purpose.

Another side of the Commission's duty is the study of the rivers of the Sacramento and San Joaquin river systems with a view to the preparation of plans for the treatment of these streams and their tributaries, so that the injurious mining detritus may be kept out of the navigable rivers and the streams restored to their former condition of navigability as far as might be needed.

The first step after preventing the operation of mines when debris is not properly impounded was the treatment of the larger tributaries to prevent the enormous quantities now in their beds from reaching the navigable streams.

In 1881 the State of California built a brush dam in the Yuba and one in the Bear river, with a view to impounding debris up to the crest of the dams. They were only a few feet high and were constructed of brush, gravel and sand bags. They were founded on the unstable gravel bed of the river. Neither dam withstood the first high water. Both streams have variable discharges, the Yuba varying from about 500 cubic feet per second in the summer and autumn to about 80,000 to 90,000 cubic feet per second during floods. The Bear river varies from about 10 cubic feet per second during the summer low water to an estimated flood discharge of about 20,000 second feet.

With these flood volumes it is evident that any dam to hold, if built on the treacherous gravel of the river bed, must be of considerable strength.

GENERAL PRINCIPLES OF IMPROVEMENT.—In undertaking the formulation of a plan for these rivers, the engineer officers adopted a general line of work that was believed to be applicable. It consisted of three divisions:

1. Building moderately high dams in the foothills where the rivers emerge into the valleys and where the value of land is not great. These dams being located where the slopes in the river bed are high, were so placed with a view to sorting the heavy material that will stand on high slopes from the fine material that will not, thus storing this heavy material where it will be impounded cheapest.

2. Embankments and basins lower down in the river, forming settling pools, where the slopes are flatter and where practically all of the finer material can be deposited by bringing the flowing water almost, if not entirely, to rest at all except high stages of the river.

3. Training walls in the remainder of the lower river, to confine the flow in selected channels, so that the large quantities of debris now in the river beds, outside these walls, should not be overflowed, and thus could lie undisturbed indefinitely.

After investigating various other plans, it was believed that the application of these principles would hold back all of the debris that could be impounded and would offer the best solution of the problem.

YUBA RIVER.—It was decided to commence with the Yuba river, as this stream has suffered more from mining debris than any other in California, and if the difficulties here could be surmounted, the methods found best adapted for the purpose would likely be more easily applied to the other streams.

After a study of several years and after extended surveys in which numerous borings were made, a plan was adopted by the Commission and submitted to Congress in 1900. The details of this plan were elaborated by Hubert Vischer, assistant engineer, under the direction of the Commission. They have since been modified from time to time as the progress of the work rendered necessary. The estimated cost was $800,000, of which the State of California, under the provisions of the Caminetti Act, agreed to pay one-half. This project was adopted by Congress and funds appropriated therefor.

The project provided for:

1. Barriers across the river just below Smartsville, to prevent the addition of coarse detritus from the upper reaches.

2. A cut at Daguerre point through which to divert the river at high stages, with embankments forming a settling basin for impounding fine material during the remainder of the year.

3. Training walls 2000 feet apart, extending from Daguerre point to the Feather river, to confine the flow to a selected channel.

BARRIERS.—The barriers were to be a system of weirs extending across the river, where the banks are high enough to afford large impounding capacity, the first located a few miles below Smartsville. This first barrier was the only one estimated for in the present project, but it was to be supplemented by others as soon as it was filled, the others to be located and built in the future when necessary.

A dam of brush, rock and gravel was first proposed, with a row of Wakefield sheet piling 20 feet deep to protect the toe. It was found impracticable to drive the sheet piling on account of the coarse and heavy material of the river bed, and this type was therefore abandoned after several hundred feet of it had been placed with much difficulty. This portion built afterward washed out during a flood in the winter of 1903–4.

A modified brush barrier was then tried by the Commission. It was a "cob-house" construction of brush fascines, forming pens 5 feet square, with an elevation of 4 feet above the river bed. These pens were filled with heavy rock. An apron 20 feet wide was made of a mattress of brush fascines fastened together with cables. This dam was destroyed by the first high water. The large amount of drift carried by this freshet broke apart the fascines and the dam soon disintegrated.

The design next tried was much stronger. It was anchored to the river bed with piles, the dam, 6 feet high above the river bed, being comprised of rock fill held in place with concrete blocks weighing about 10 tons, molded in place over the rock fill, and connected together with wire cables imbedded in the concrete. Leakage was checked by timber bulkheads. A broad apron, 20 feet wide with a 6-foot extension, diminished the scour at the toe, that otherwise would have undermined the dam. A sloping upstream face prevented damage from drift.

It is thus seen that most of the weaknesses of the previous dams had been remedied in the new type. This dam has just passed successfully through its first high-water season and is the first to withstand a single freshet in the lower Yuba river.

The dam consists of four rows of piles, the two upper intervals between rows being 10 feet, and the interval between the third and fourth rows being 18 feet.

Piles were 6-feet centers in the uppermost row, 12-feet centers in the two middle rows, and 3-feet centers in the lowest row. Every 12 feet the piles in a tier up and down stream were connected at their upper ends with 1-inch galvanized wire cable. A timber bulkhead 3 inches thick was spiked to the upstream and another to the downstream row of piles, and was carried as deep as the water in the river would permit.

Between the first two rows of piles was placed a fill of rock which was brought up to a subgrade, so that when covered by the concrete blocks, 1½ feet thick, the height of the barrier would be 6 feet above the average level of the river bed. Concrete blocks about 10 feet square and 1½ feet thick were built in place over all this fill, connecting by means of a rollerway with an apron 20 feet wide resting on the river bed below the dam.

The upstream slope was protected with an inclined layer of large rock laid in Portland cement

Brush and Rock Dam on Yuba River, Cal., Later Destroyed by High Water.

Down Stream Face of a Log Crib Dam.

*See illustrations on front page.

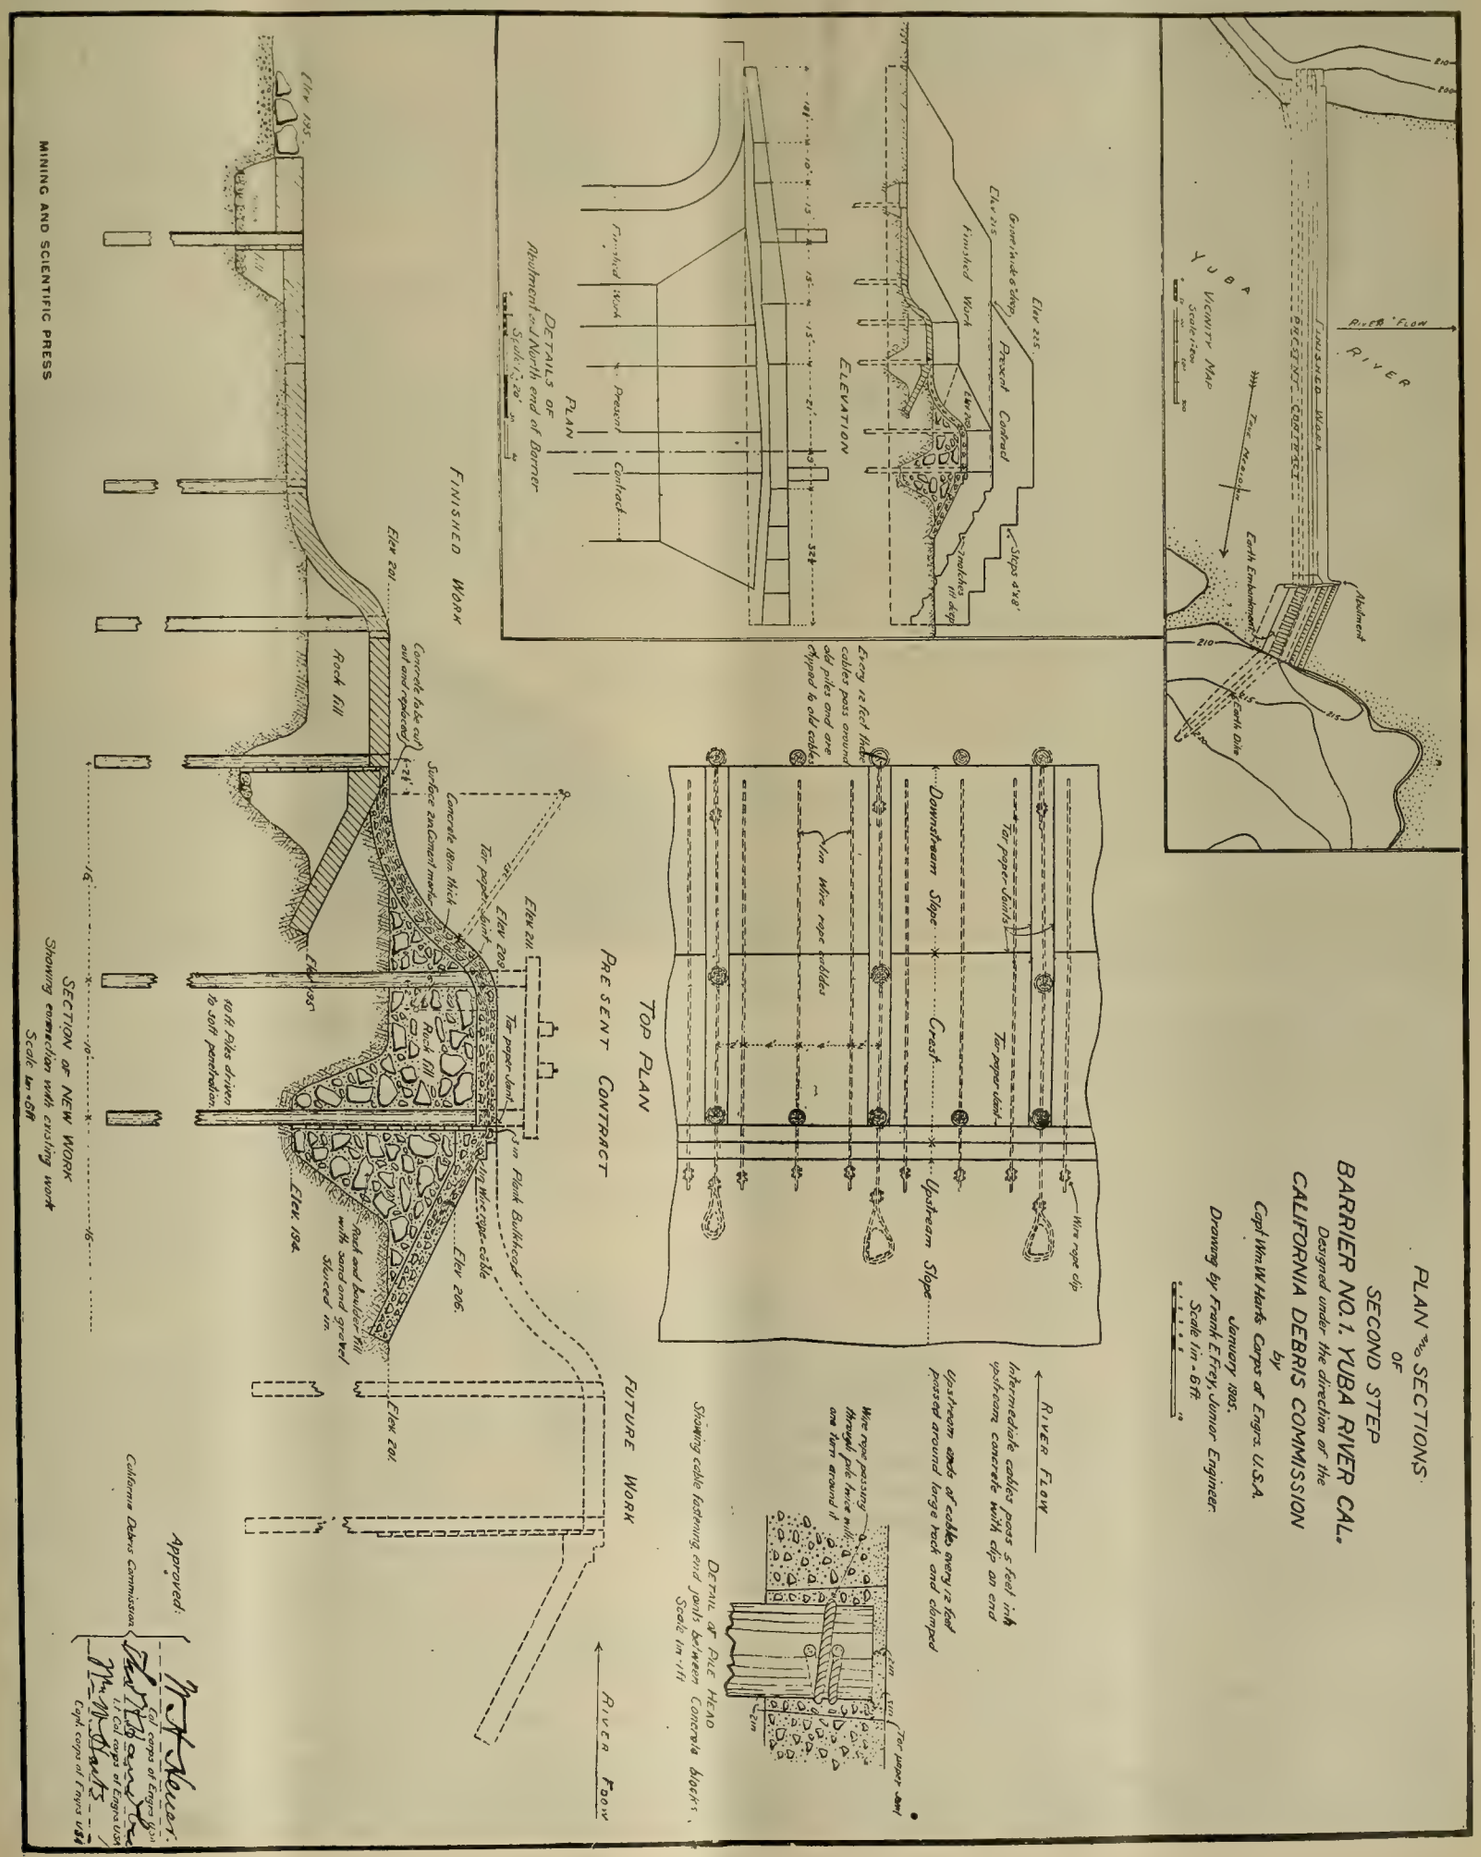
mortar. The concrete slabs of the top surface of the dam and those of the apron were separated from each other by tar-paper joints, and, to prevent dislocation by the river currents, were connected in the direction of the stream flow with 1-inch galvanized wire cables, 3 feet apart, imbedded in the concrete. The cables connecting the piles referred to above were also imbedded in a narrow strip of concrete 18 inches square, which helps bind the heads of the piles together in each tier and separates the large blocks.

Excepting these narrow strips, the concrete slabs rest on the river bottom only and are not supported on the piles. They are jointed so that they are free to move vertically, the cables acting as a hinge.

This, it was designed, would permit the concrete blocks to follow down any considerable scour under the apron, should it occur, and thus prevent any serious damage to the dam due to back-lash.

The weak place in all over-fall dams on poor foundations is, of course, the toe. The rollerway and apron it was hoped would protect the river bed from excessive and dangerous scour. In addition, an extension or lip of masonry 6 feet wide was placed below the apron to carry the water farther away from the toe, and if underscoured it would break up, fall in the hole and offer protection against further action. In addition, for about 600 feet the dam at the south end, where the scour was believed to be strongest, was further protected by large rock or rip-rap placed at random.

The south end of the dam was joined to the bedrock of the river bank, but at the north end a concrete abutment was built, founded on piles, to act as a retaining wall for the earth embankment which was later built to connect the dam with the shore. The north shore is composed of compactly cemented



gravel, through which it was originally planned to have a spillway constructed to carry the river at all stages except flood. During construction the entire river was permitted to pass between this abutment and the north shore before building the embankment, so that the concrete dam could be constructed entire on the dry river bed. When it came time to close this gap through which the river flowed, it was found to be an undertaking far greater than was anticipated, as there were about 1200 to 1300 cubic feet per second flowing around the end of the dam. This flow had to be lifted upwards of 8 feet over the completed structure.

The first pilework placed to close this gap failed with the pressure of water, and through the serious scour in the bottom which took place while trying to close the opening. Later more piles were placed in the opening, and by the liberal use of brush and sand bags the gap was finally closed.

Much assistance was afforded by an auxiliary dam or levee in the river ¼ mile upstream, hastily built to divert the flow over the dam and away from the cut. Over 20,000 sand bags were used in closing this gap, as no rock was available. As soon as closed the gap was filled with an earth embankment. The experience with the north bank near the end of the dam has decided the Commission to change the location of the spillway from the north end to the south bank, where the cut will be in rock.

This spillway will be 400 feet wide on the lip and 4 feet deep, taking a flow of 13,600 second-feet before the dam comes into use, so that the river will be carried around the south end of the dam at all stages except for a short time each year at flood stages. This will make the dam when completed practically permanent and easily maintained.

The first step of the permanent dam having been completed as above described, it is now proposed to build in accordance with the project a similar step 8 feet higher, lying upstream of the present work and connecting with it. Contracts are already let and work has been commenced on this second step.

In the same way it is expected to put a step 8 feet high on the dam each working season. In this way the ultimate height of the dam will be reached by successive steps. This method was found advisable, as the amount of work possible in the river bed during the low-water season is limited and time must be given the river to fill each step with gravel.

The first step, already built, has been filled with gravel to its crest since the first heavy freshet, and gravel as large as pigeons eggs have been rolled over the top of the dam for several months.

It is thus plainly seen that the dam as a whole is a gravel fill dam sluiced into place by the river itself, the downstream slope of which is composed of a layer of concrete blocks having a general inclination of about 1 vertical to 3½ horizontal. The concrete overlies a rock fill held in place by a framework of anchor piles and timber bulkheads.

The first piling were driven by the United States, because it was not believed advisable to contract for this work at first, as the risk was considerable and it was freely predicted by some engineers that no piles could be driven in the Yuba river bed at that place.

This work, however, was carried to completion without notable difficulties, 888 piles being driven with an ordinary land driver equipped with a 20 H. P. Lidgerwood engine and a 3500-pound hammer working in 45-foot gins. The driving was difficult, each pile requiring from 150 to 250 blows. The piles cost from 19 to 23 cents per foot delivered in Marysville, and 10 cents per foot to haul to the site of the work, 17 miles farther. This made each pile cost about $12. The driving cost $5.02 per pile, making the cost of each pile in place about $17. Including experiments with water jet and accidents, the cost was $19.74.

This price was considered high at the time, but the work under the contractor thus far this spring on the second step, it is believed, has exceeded this price. Under contract, the new piling has cost 31½ cents per foot per pile delivered at the site of the work, making each pile cost $12.60. The contract price for driving is $7.60, making each pile under contract cost $20.20 in place.

Portland cement costs $2.785 delivered at the site of the work. Concrete was mixed by hand and was made from gravel and sand taken from the river bed and screened. It was mixed in the proportions of 1 cement, 2 sand, 2 gravel and 4 cobbles passing a 2-inch ring.

The work on the first step, including the abutment, cost as follows, prices including placing:

Excavation, 6,470 cubic yards at 30 cents	$ 1,941 00
Lumber, 61,655 feet, board measure, at $40	2,466 20
Loose brush, 95 cords at $3 50	332 50
Large rock, 2,411.75 tons at $2	4,823 50
Large rock in cement, 1,621.367 cubic yards at $7	11,349 15
Small rock fill, 4,251 tons at $1	4,251 00
Cable, 30,300 linear feet at 18 cents	5,454 00
Concrete, 3,754 2 cubic yards at $7.50	28,156 50
Extra work	1,300 10
Total	$60,073 95

The entire dam, including piles and excluding abutment and embankment, cost in round numbers $78,613, or about $63 per linear foot.

DAGUERRE POINT SECTION.—The plans for the treatment of the intermediate section of the Yuba river involve the construction of high embankments across the river in a V-shape, with the apex upstream, the ends connecting, one with Daguerre point on the north, and the other with a high knoll on the south bank.

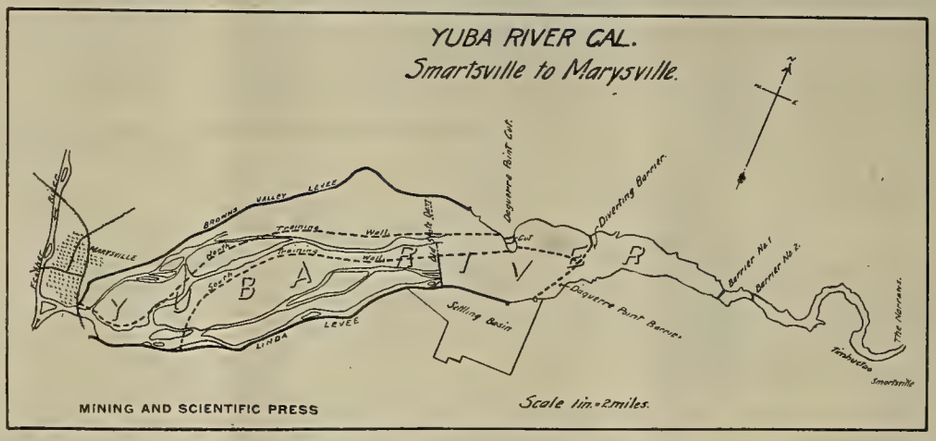
A diverting barrier connects the apex of the V with the north shore, diverting to the south all water below the elevation of its crest. Through Daguerre point is being cut a channel 600 feet wide and 25 feet deep, through which all the river flow at high stages will pass.

On the south bank, regulating works will admit all the water diverted by the diverting barrier below a limit of about 6000 to 7000 second feet, passing it into a natural depression of about 2 square miles and lying adjacent to the river on the south. These works will exclude all flow above what is considered safe, compelling the excess to pass to the north over the diverting barrier and through the cut.

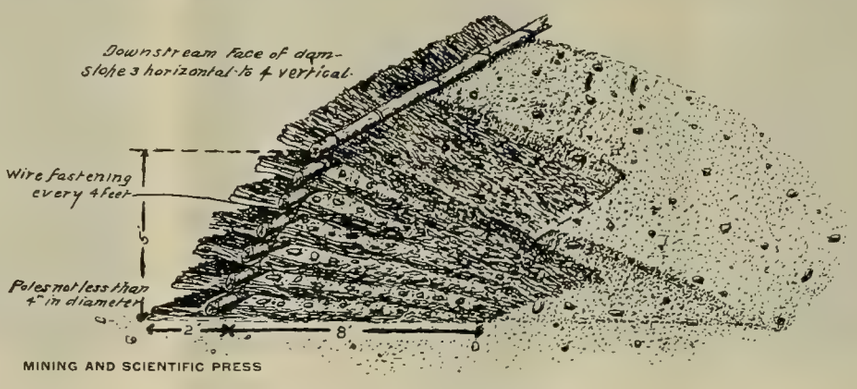
This plan is simply taking advantage of the natural regimen of the river.

All rivers have their sections of active erosion, usually where slopes and velocities are highest, their sections of transportation where slopes and velocities are sufficient to carry sediment but not to scour, sections of sedimentation where the reduced velocities permit the sediment to fall and form deposits, and the section of discharge.

The construction of the embankments and the use of a large settling basin only increase the natural area of the section of sedimentation. The river is passed into an area where the velocities are checked, although not entirely overcome, so that practically all their load of sediment is dropped. The water passing back into the river at the lower end of the basin is practically clear. At stages of the river occurring for a short time only each year, where the flow of water through the settling basin would be more than could be settled, the regulating devices will exclude the excess, causing it to pass into the cut. This will happen only in such high stages that the velocities are thought to be sufficient to carry whatever fine sediment is in suspension into the Feather and Sacramento rivers, which, being in flood at the same time, will carry the sediment into the tidal currents of the bay and thence into the ocean. The solution of the extreme high water part of the problem is not thoroughly satisfactory, in view of the fact that adequate levees are not yet built on the Sacramento to control its flow; but as the periods of such high water are short, the damage, if any should result, will be limited and will vanish when the Sacramento is regulated—a vast problem now receiving attention.



Sketch Map of Yuba River Near Marysville.



Method of Constructing Brush Restraining Dam.

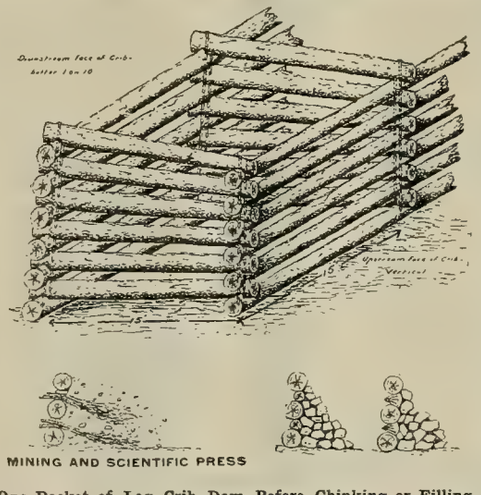
Work in the vicinity of Daguerre Point has been in progress for considerably over a year. Of something over 700,000 cubic yards excavation, about 504,000 cubic yards have already been removed.

A steam shovel having a 1½ cubic yard dipper is used, the excavated material being removed by two trains of about ten cars each to the dump at the north side of the entrance. An average of 30,000 cubic yards per month is required under the contract, which should be completed by the close of the calendar year. The contract price of excavation is 23½ cents per cubic yard of earth and 90 cents per cubic yard of rock removed. The total cost of this cut will be something over $160,000.

It was originally intended that the United States should build the embankments across this part of the river; but before operations could be begun it was found that a gold dredging company had secured extensive mining rights in the vicinity that promised to conflict decidedly with the plans of the Government. It was also learned that the company, in the exercise of its rights, proposed to dredge for gold in the river bed just where the original settling basin had been located. After considerable controversy, an amicable agreement was reached by which the Commission was enabled to obtain a larger settling basin on the south side of the river in exchange for the first adopted location; certain deeds to property were secured which were essential to the project, and the company also agreed to build the embankments necessary free of cost to the United States and give them back their originally located settling basin when it had been mined.

These terms were distinctly advantageous to the United States and made a considerable saving in the cost of the work.

Under this agreement about 2000 linear feet of embankment, about 30 feet high and about 300 feet wide on the base, have already been built near the apex of the V. These embankments are made while mining by stacking the dredged material in a mound



One Pocket of Log Crib Dam Before Chinking or Filling.

behind the dredger as it digs ahead through the river bed.

It is expected to have the cut through Daguerre Point completed by the end of 1905 and the embankment connecting Daguerre Point with the south shore by the end of 1906.

TRAINING WALLS.—In the section of the river between Daguerre Point and Marysville the project calls for training walls to confine the channel to one location. Whether these walls shall be high dikes or levees throughout to positively control the river even at high water, or whether lower and partially permeable dikes, partly built of living brush and thus to act only as guiding walls, shall be adopted, has not been fully decided for the lower sections. The result of the first high sections now being built near Daguerre Point will likely determine this question when their action at high water is learned.

Already considerable has been accomplished beside obtaining rights of way from the owners. Securing these rights was a first consideration and has been exceptionally hard in some places on account of the gold dredging fever, which has made each owner believe that he has a valuable mining property. The necessary rights have, however, been all secured, with some minor exceptions.

In addition, agreements have been made with two gold dredging companies to build free of cost to the United States the south training wall from Daguerre Point west for a total length of about 2 miles, and dredgers are now being built for this work as an incidental to their gold dredging operations.

Contract has been made for the north wall along a parallel line for a total length of about 2 miles. This work will be commenced this summer and completed within a year by scraping. The contract price is 12.4 cents per cubic yard in place for about 200,000 cubic yards. This wall, with the south training wall, to be built without cost, will control the floods of the Yuba river for their length of 2 miles, confining the river to the 2000-foot space between the walls. They will be 11 feet or over in height and will not be overtopped.

It is, of course, too soon to prophesy what success will attend this work; but the encouraging start made and the good results obtained as far as work has proceeded are certainly encouraging.

BEAR RIVER.—As stated before, the Yuba river was the first to be studied and the first to be taken up for treatment. The Commission are now planning to take up the work on Bear river, and a survey is authorized and is now being arranged on which to base plans for the future improvement of this stream.

Should the Bear river work be approved by Congress and by the State of California, and funds provided, the work will be extended to the American river and other sediment-bearing streams until the entire problem is solved.

Captain Harts illustrated his lecture by photographs projected on a large screen in front of his audience, graphically portraying the salient points of his discourse. The accompanying illustrations and those on the front page aid in furnishing an intelligent understanding of the present phase of this great work. For opportunity to use them the MINING AND SCIENTIFIC PRESS takes pleasure in acknowledging the courtesy of Wm. M. Harts, Capt. Corps of Engineers, U. S. A., and Mr. Otto Von Geldern, vice-president Academy of Sciences, in furnishing the photographs from which they were engraved.

Spitting and Snuffing of Fuses.

In view of the increasing number of fatal explosions in mines at Bendigo, Victoria, the relative merits of the methods of "spitting" and "snuffing" of holes have been discussed at some length and the Mining Managers' Association have seriously considered the matter, says the Australian Mining Standard. The practice in vogue is to charge several holes at one time, and either "spit" or "snuff" the fuse. The former system is to merely ignite the ends of the fuse, while "snuffing" consists of placing a small piece of lighted candle, called a "snuff," under the fuse, thus requiring the outer covering of the fuse to be burned through before the powder catches. In coal mining this is called "smift" or "snift," and consists of a bit of touch paper, touch wood, etc., attached by a bit of clay or grease to the outside end of the train of "gunpowder" when blasting. It appears that six fatal accidents have occurred in the Bendigo district within the past five years from "missed" holes. At the recent inquest on the bodies of the miners who were killed at the Virginia mine, Bendigo, Mr. Abrahams, Inspector of Mines, made strong objections to the practice of "spitting" holes. The representatives of the A. M. A. held different views on the methods of firing. Miners of forty years' experience contended that "snuffing" was the only safe way; others of less experience maintained that "where a man could get away easily 'spitting' was equally as safe as 'snuffing.'" Eventually, however, the following recommendations were adopted: "(1) That the safest method of firing is by using snuffs to fire all holes; (2) that four holes be the maximum amount fired, and not more than three holes when they are dependent one upon another in any one stope or place; (3) that not less than 6 inches lead of fuse shall be given to each hole fired; (4) that these recommendations be forwarded to the Minister of Mines, and also to the Mining Managers' Association." W. Curtis took exception to these proposals, and said that, in view of the fact that the fuse used in the Bendigo mines was about the best in the world, a far greater number of holes than that recommended could be safely fired. At the meeting of the Mining Managers' Association, J. Veale said that he had found the practice of "spitting" holes preferable to "snuffing." Mr. Rodgers said that he had frequently reprimanded miners for firing too many holes at one time, and they had replied that they were saving time. The Association decided to take no action in the matter. It is generally recognized that most of the accidents have been due to the carelessness of the miners themselves, for they have been known to carry pieces of dynamite about in their waistcoat pockets down below. Only last week a tributor at Bendigo had his house blown to pieces through using it as a magazine, there being twenty sticks of nitro powder, dynamite caps and fuse stored in a box in one of the rooms. Referring to the risks which miners accept, W. Abrahams says, in his annual report for 1904: "In the three fatal accidents, two men were killed while boring into the bottom of old holes with rock drills. This shows how careless miners are; in either case there was no necessity to bore into the old holes, and until miners exercise more care there will be accidents. Another man lost his life using an old rope, absolutely rotten, for a swing stage to repair a small alluvial shaft. These lives were carelessly thrown away."

International Atomic Weights.

The following from the Journal of the London Chemical Society is the list of atomic weights as issued by the International Committee with their report for 1905:

		O=16	H=1
Aluminum	Al	27.1	26.9
Antimony	Sb	120.2	119.3
Argon	A	39.9	39.6
Arsenic	As	75	74.4
Barium	Ba	137.4	136.4
Bismuth	Bi	208.5	206.9
Boron	B	11	19.9
Bromine	Br	79.96	79.36
Cadmium	Cd	112.4	111.6
Cæsium	Cs	132.9	131.9

Zirconium	Zr	90.6	89.9

Responsibilities of Australian Mine Managers.

Written for the MINING AND SCIENTIFIC PRESS by R. B. LAMB.

The law regulating mining operations in Australia is very strict in all States of the Commonwealth. Although the Eastern States do not labor under the stringent legal disabilities of the West, the laws in relation to the operation of underground workings and surface equipment are almost uniform throughout the continent. Inspectors of mines are appointed by examination, the successful applicant holding the position for life, if he strictly carries out his official duties. His power is fixed by the Mines Regulation Act, and he is directly responsible to the Minister of Mines for the time being, to whom he reports. He makes regular visits to all mines throughout his district, and during his stay on the mine he practically is the general manager of the mine, any workman or employe being compelled to answer his questions or carry out his directions. His jurisdiction underground is very great. Stopes, etc., which he considers unsafe must be secured. He may direct that all mining elsewhere in that mine shall cease until the part has been secured to his satisfaction. Any order he may give in regard to hand rails, covers over winzes, etc., must be promptly carried out. Should the manager fail to comply, the inspector prosecutes before the warden's court to enforce his directions. In the matter of explosives the law is very rigid. Should the inspector see explosives in a stope, or in or around a mine, outside of a magazine, not in the regulation canister, the manager is liable to be heavily fined. The surface equipment must be rendered safe as the law directs. Belts, etc., must have hand rails. Should the manager fail to provide these things, the plant would be closed down until it is accomplished. Boilers are inspected twice yearly, and may be condemned if considered unsafe, or the steam pressure lowered. Should a manager work a condemned boiler, he is heavily fined and the plant may be closed down. Should a fatal accident happen from a condemned boiler, the manager is guilty of manslaughter. In Western Australia, in addition to the inspector of mines, inspectors of boilers and machinery are appointed, whose duties consist of testing and examining all boilers and machinery, and the same cannot be started without their certificate. In no part of Australia can any plant be started to operate until passed by the inspector.

Cages and wire ropes are regularly tested by the inspector and may be condemned by him when considered unsafe, and they cannot be worked when condemned.

In Western Australia wire ropes are not allowed to become covered with thick grease; every strand in the rope must be visible to the eye. The inspector can direct the testing of ropes or cages at any time, and the manager in all cases is bound to carry out his orders. The disinfection and sanitation of the mine are thoroughly looked into by him, and the manager must see to it that any recommendations or orders are promptly carried out as he directs. Certificated men only can be employed on hoists, boilers and stationary engines. The manager must see their certificates. Should a fatal accident happen with an uncertificated man at the hoist, the manager is guilty of manslaughter. Work at mines is not permitted on Sundays, except in special instances, such as on pumps, necessary repairs, etc., to do which a permit from the inspector is necessary. The Australian law is uniformly strict in the matter of accidents, either underground or on the surface.

Should an accident happen, fatal or otherwise, no matter how trivial, the inspector must be immediately notified. In case of fatal accident, the place where it occurred must not on any account be disturbed. If underground, no work must be done until he orders it. If on the plant, it must remain stationary until after his examination The inquiry into serious or fatal accidents is very rigid, and in Western Australia a fatal accident renders the manager guilty of manslaughter. In east Australia, if any part of the Mines Act has not been carried out, a fatal accident would mean that the manager is guilty of manslaughter. In all cases of fatal accidents the manager must appear before a jury and must, if any negligence has been shown, stand trial for manslaughter. He may further be sued under statute law by relatives of the injured or dead person for damages, which, if negligence has been shown, will be awarded. In cases of serious accidents the manager, if regulations have not been carried out, will be heavily fined and may be further sued by the injured man for damages.

In all cases of accident the manager must promptly secure medical attendance and relief for the sufferers, regardless of cost.

Should any workman or others report to the inspector any non-observance of the mining regulation on the part of the mine manager, the inspector must immediately examine the same in company with the manager.

Two or more miners, if they consider the mine unsafe to work in, may report the same to the man-

ager, who is bound to notify the inspector and have him examine the same.

Should any miner report an unsafe place to the manager, and an accident occur, the manager is guilty of an offense against the Act and punished accordingly.

In Western Australia compulsory arbitration is in force, and both workman and manager are bound by its awards. The workmen cannot strike, or they commit an offense against the Act and are punished. Neither can the manager go outside the award, or he commits an offense against the Act. Australian mine managers, therefore, are compelled to operate their mines in accordance with the mining Act, and any failure to do so renders them liable to severe penalties.

The Ventilation of Mines.

NUMBER III.

MEANS SUGGESTED FOR IMPROVEMENT OF VENTILATION.—In this State the main problem is the bettering of the ventilation of the metalliferous mines, especially those which are large and deep. As regards the collieries we need add very little to what has been said in a preceding section, the need being for the application of well-known practices rather than for any new or less usual expedients. The provision of better designed and more powerful fans, and more attention to keeping stoppings, air doors, and brattices in good order, and to carrying the brattices well up to the faces of the bords, are all that is necessary to make the ventilation as nearly perfect as possible, except that in long headings, slants, and inclines driven for exploration purposes ahead of the main work, the same devices must be used as in long drives and crosscuts in metalliferous mines, in order to carry air to the working faces. The blasting being as a rule much lighter than in our gold mines, it is usually possible in the collieries to thoroughly ventilate such workings by the use of bratticing; in other cases ventilating pipes may be preferable. In some parts of the Collie mines also, the ventilation would be much improved by greater attention to draining the traveling ways, so as to prevent them from becoming exceedingly muddy and filthy, as at present, as the trampled dirt, especially on the horse roads, is often very foul-smelling.

In the metalliferous mines the practicable means of improving the ventilation may be divided into—(1) Connections between workings to bring about circulation of the air; (2) Appliances for systematizing and regulating the air currents; and (3) Devices for mechanically ventilating the whole or any portions of the mines.

Connections Between Workings: The best means of securing thorough natural ventilation is without doubt the use of two (or more) separate shafts, one of which is an upcast and the other a downcast. When the workings of adjoining mines can be connected, the same effect may be secured, the air passing down one shaft and up the other. In the shallower portions of mines it is usual for at least two shafts to exist, but as they get deeper the workings are apt to become concentrated more and more round a single shaft. The sinking of a second ventilating shaft of equal depth to the main working shaft would often be so expensive as to be quite out of the question, and in deep mines it is only when there is a very large quantity of mineral to be raised and the workings are very extensive that it is possible to provide two main shafts. The adoption of the colliery rule that all mines must have two shafts is, therefore, quite impracticable in a great many metalliferous mines. It is generally quite practicable, however, to have a second connection from the lowest workings to the surface through winzes and worked-out ground, and where these openings are of sufficient area and are kept sufficiently clear to constitute a good air passage, they have the same effect as a second shaft in bringing about good ventilation. Care should be taken in all mines that such air passages are made of sufficient size in the first place, and are kept open constantly afterwards. It very often happens in this State, as elsewhere, that they are much too small, and also that they are used as ore and mullock passes, so often becoming blocked. In every important mine there should be at least one air way, in addition to the shaft, of large size, maintained quite unobstructed from top to bottom of the workings, and kept for ventilation and traveling purposes only. In sections of mines where the ventilation is defective, care should similarly be taken to have one or several clear air passages from level to level. The system of using "rearings" when filling stopes with mullock, so as to leave a space between the filling and the unbroken reef, is very commendable from the ventilation point of view, besides being an excellent practice, for other well-known reasons.

The construction of winzes to enable the ground to be blocked out, and the formation of ore passes as the stoping proceeds, usually cause the ventilation to improve very much as the mines become better opened up, but during the development period, before the connections are completed, it may be very defective. To remedy this by connecting at the earliest possible moment is, then, the only practicable course if natural ventilation is relied on entirely, and in the meanwhile the men may suffer considerably. To minimize this, the levels should not be too far apart, and connections between them should be as frequent as the nature of the mine permits. This is readily enough attained when the levels are in good ore, but when they are passing through poor or valueless portions of the lodes it is impracticable to insist on frequent connections. The distance between levels is governed by several considerations, such as size, value, and underlay of the ore bodies, their length and relative position, and the hardness of the rock to be driven through. It may be most judicious and economical to drive the levels 60, 80, or 100 feet apart vertically, or it might pay best to have them 150, 200, or even 250 feet apart. So also in one case the levels might be connected by winzes or rises every 100 feet apart, while in another, owing to small size of the lode, or poorness of the ore, it might be necessary to have them a long distance from one another. It is therefore impossible to lay down any hard and fast rules regulating the permissible distance apart of levels and winzes, and great discretion must be allowed to mine owners in deciding what they had best do. In some cases it may be necessary to carry down a main shaft several hundred feet before again opening out, in order to pass through an unprofitable zone in the lode, and the question of connections then becomes a very serious one. It may then be better to install some mechanical means of ventilating the lower workings, instead of attempting to maintain natural ventilation. We are of opinion, however, that even in these extreme cases, if the ore developments are at all extensive and valuable, it will usually be economical to make a winze to secure another air way independent of the main shaft. Besides being advantageous for ventilation purposes, a connection separate from the shaft, which can be used as a traveling way, is a great safeguard for the workmen in the not impossible event of the main shaft being wrecked by explosion, accident, or fire. The sinking of winzes is, of course, also a well recognized means of prospecting the ground, and valuable from that point of view. In order to have the connections available at the earliest possible date, we would recommend that the sinking of winzes should, whenever practicable, be carried out simultaneously with the sinking of the main shaft, and the driving therefrom, so that the drive may connect early with the bottom of the winze.

The ventilation of deep mines from a single timber-lined shaft is attended with many difficulties, it being nearly impossible to line the compartment so closely as to prevent leakage from the downcast into the upcast one. At the chambers where the levels join the shaft, also, it is very difficult to prevent short circuiting of the air. It is obvious that unless the downcast current is led into the level and the upcast one out of it quite separately from one another, no considerable circulation can be relied upon. By putting a door on one or other compartment of the shaft and leading the air from or into it by a large box under or over the plat, which in turn communicates with an air way formed in the level by bratticing or boxing, it is possible to keep the ingoing and returning air currents separate from one another, but the method is rather cumbrous, the air boxes are difficult to maintain free from leakages, and, if the door is placed on one of the winding compartments, the constant opening and shutting of it when using the cage interferes very much with the air currents. It is best to have the winding compartments both upcasts or both downcasts, and to make the pump or ladder shaft the other air way, as a door on it need rarely be opened; but the state of wetness or dryness of each compartment often has a great deal to do with its being an upcast or a downcast, and without the aid of an artificially produced draught it is frequently not possible to insure that the air will travel in the direction it is wanted to go. The pump shaft may be closed at the top, only leaving room for the rods to work through the cover, and connected with a tower or stack on surface of height sufficient to cause a constant draught. Sometimes a fire is used in the bottom of a stack to increase its natural draught. An exhaust fan at surface would obviously be an even better solution of the problem.

When the pump shaft is used as a downcast and the winding compartments as the upcast, a convenient way of leading the air into each level is by the old and well known method of a deep covered drain under the plat and floor of the level, by which the intake air may be carried right up to the ends of the drives. These air sollars, to be effective, must not be too small, and the method involves a good deal of expense in extra excavation and in the close planking required to cover the drains. They are, however, much less liable to be destroyed than boxes along the sides of the drives or sollars along the roof. Many of our witnesses mentioned the floor sollar system with approval, as having been successfully used elsewhere, especially in Victoria, but we did not see an instance of its use in any of the mines visited. The system of taking out leading stopes along the backs of the levels, and at the same time timbering the levels so as to divide the air way, was also very properly regarded as commendable in cases where circumstances rendered it applicable, the air travelling in along the level and back through the stope. In all the cases examined by us, however, where one shaft was the only entrance and exit for the air going into a level, no trouble was taken to separate the currents, and the circulation was confined to an almost imperceptible flow of the cooler air inwards along the floor, and a corresponding return current along the back of the level. The ventilation was generally poor in consequence, and the air from the rock drills was greatly relied on to keep the faces in a workable condition, and to blow out the smoke. Haste should always, therefore, be made to obtain connection with higher levels by winze sinking and rising, which, when completed, furnishes a separate air way to the surface, and does away with the need for having both ingoing and outgoing air passing in opposite directions through the same shaft or drive. Ventilation from a single shaft alone is, therefore, rarely expected to be more than temporary. An instance of somewhat extensive workings was, however, seen in Bayley's mine at Coolgardie, where there is no opening, except the main shaft, between the 600 and 800 foot levels. The three lowest levels are connected by winzes, but no attempt was made at the highest of the three to confine the return air to the upcast compartment of the shaft, and there was nothing to prevent it going down the downcast shaft again back into the workings. The generally bad state of the air in these levels, disclosed by Mr. Mann's analyses, and very appreciable to visitors by a sensation of great heat and stuffiness, was doubtless due to the same air being circulated over and over again. In this instance it seemed to us easily possible to allow only the downcast air from surface to go into the bottom level, to cut off its return to the shaft at the next higher one so as to compel it to go up to the next one, and to lead the whole of the return air into the upcast by the use of a fairly simple system of doors.

The question of connections between different mines to aid the ventilation is one that has a good many aspects. There is no doubt that they bring about a great improvement in the mine which happens to be the downcast, and often also in the one which is the upcast, but there are cases where the latter may be detrimentally affected by receiving the smoke and vitiated air from the first. A mine which is itself well ventilated may reasonably object to becoming the upcast for its neighbor. It is therefore a question how far it is fair in such a case to force on a mine, which does not desire it, a connection which will benefit only its neighbor.

Cases were mentioned to us by witnesses who had been at Charters Towers of men in some of the upcast mines being much incommoded by the smoke from mines below them. There are also instances at Kalgoorlie, and more than once the connections have been closed by the mines who were receiving their neighbor's smoke. There are now a great many of the principal mines at Kalgoorlie connected one with another, and the general result has been undoubtedly a great benefit in the ventilation on the whole, but it is unquestionable that there have been occasional cases of hardship inflicted thereby. The benefits so far outweigh the disadvantages, however, that we are of opinion that connection should be permitted whenever a reasonable case is made out for it, and so long as the neighboring mine cannot show strong grounds for objecting. In case of such objection the mine benefited might reasonably be required to go to the expense of diverting its fumes through the neighbor's workings so as to keep them away from the latter's men. This could often be done by leading them through rises and the ends of stoped ground so that the ventilation of the working faces would not be interfered with. When a boundary between two owners crosses a payable lode a winze or pass on the intersection, made at the joint expense of both, would be one of the best solutions of not only ventilation difficulties, but some others also which do not concern the present question. The decision as to when connection between mines may be made compulsory, in the event of amicable arrangement between the owners being impossible, and as to the terms on which it may be made, can hardly be the subject of fixed regulations, the circumstances of each case demanding separate inquiry and adjudication. An independent board to consider and settle such disputes seems to us the best solution of the problem. The guiding principle should be, according to the theory of mine tenure in this state, that, the mines being the property of the Crown, it may demand that the lessees work in such a way as will be for the general advantage of the public estate, and consequently may insist on the connections being made if the mining industry in the district is thereby benefited. At the same time the recipient of immediate benefit should do the utmost possible to protect his neighbor from any evil consequences of the connection, and compensate him for actual damage.

(TO BE CONTINUED.)

IN mine examination the expert is constantly devising means for the detection of salting his samples, should this have been done, and many and ingenious are the ways by which he attempts to determine this important point, but it should always be remembered that it is even of greater importance to prevent being salted. This is far more difficult than the detection of the fraud after it has been accomplished. There are several reliable methods by means of which salting can be detected, but to absolutely prevent it requires constant vigilance at every step in the process.

Cyaniding Silver-Gold Ores of the Palmarejo Mine, Chihuahua, Mexico.*

NUMBER VI.

Written by T. H. OXNAM.

Each agitation vat was originally provided with a 6-inch discharge opening at the center of the bottom casting. This opening was bushed down to 4 inches and was provided with a nipple and a straightway valve. The first few vats were discharged from the bottom by this means, but a great deal of trouble was experienced, due to the fact that though all the slimes entering the agitation vats were passed through a grizzly having 1.25-inch openings, the bottom valve would frequently become choked with small rocks and other solid material which seemed to become unavoidably mixed in with the first slime treated. This bottom discharge was therefore discontinued and a hole was bored in the bottom staves, about 10 inches from the bottom casting, and a 3.5-inch iron service cock was secured to the vat by means of a short nipple and iron flanges. The vats are discharged through this valve into a wooden launder which conveys the material to the corresponding decantation vat. This launder is provided with rows of 6-inch wire nails, which serve to remove any small pebbles or other foreign matter.

The four decantation vats, made of 3-inch redwood throughout, are of the same dimensions as the agitation vats, with the exception that they are provided with conical bottoms, slanting at 20°. Each one is connected with an ordinary 3-inch centrifugal pump. Fig. 7 shows in detail the connection of the pump

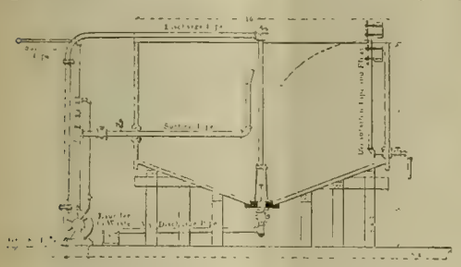

Fig. 7.—Decantation Vat and Pump Connections.

with the vat, which is practically identical with that of the agitation vats and pumps. The vat is discharged through a 3.5-inch bottom discharge vat and pipe into the residue launder, from which the discharged material flows to the river. Removal of the clear solution is effected by means of a 2-inch decantation pipe and float. This pipe enters the side of the vat, about 6 inches above the bottom staves, and is provided with two loosely threaded elbows, which permit of the free raising and lowering of the portion within the vat. The float proper is made of two ordinary 5 gallon oil cans, soldered water tight and painted with paraffine paint. The rate of decantation is controlled by means of a 2-inch valve just outside of the vat.

It frequently happens that the solution drawn from the decantation vats is not perfectly clear and two filter boxes are provided (see Figs. 4 and 5) for the, at least part, clarification of such solution before it enters the solution tanks at the head of the zinc boxes. Each compartment of these filter boxes is provided with a discharge valve, by means of which the sediment deposited from the solution can be washed into a discharge launder and run to waste. In practice, however, it is found that these boxes are not sufficiently large to carry all the solution and, therefore, that portion coming from two of the decantation vats is run directly to the solution tanks.

The solution tanks at the head of the zinc boxes are two in number—one being used for the weak and the other for the strong solution. They are made of 2-inch redwood throughout and are each 11 feet 8 inches in diameter and 7 feet 7 inches deep, inside measurements, having a capacity of 25 tons. Each solution tank is provided with a 2-inch floating hose, by means of which the clearest solution in the tanks is always supplied to the zinc boxes. A 3-inch opening in the bottom of each of these solution tanks provided with a valve permits of the periodic discharge of the accumulated settled slimes into a waste launder.

Fig. 8 shows the timber foundations supporting the decantation vats, the conical bottoms resting on the three beveled rings shown. The supports for the agitation vats are built in the same manner, the supporting rings, however, being placed to line at 45° instead of at 20°. Fig. 9 shows the decantation vats in course of erection.

There are four sets of zinc boxes, each set being composed of six round individual boxes or compartments, each compartment being 28 inches in diameter and 2 feet deep, and having an available zinc capacity of approximately 5 cubic feet. One of the boxes is used solely for strong solution and two for weak solution, the fourth being so connected up that either weak or strong solution may be run through it. The solution leaving the zinc boxes passes to three sump tanks, made of 2-inch redwood throughout, each 11 feet 8 inches in diameter and 9 feet 7 inches deep, inside measurements, and of a capacity of 32 tons of solution. Two of these tanks are connected together and serve as a weak solution sump, the other being used for the strong solution.

Fig. 10 gives a good view of the plant shortly before its completion and shows its general arrangement. Fig. 11 gives a nearer view of three of the agitation vats and shows the tops of two of the decantation vats. The 4-inch centrifugal pump connected with No. 1 agitation vat is seen partially connected up. Protruding from the top of the decantation vat, a little below the center of the picture, is seen the end of one of the 2-inch decantation pipes.

METHOD OF TREATMENT.—The accumulated slimes, after having been allowed to dry in the slime pits as much as practicable, are conveyed to the agitation vats in ordinary half-ton ore cars by means of the small, friction-geared hoist already mentioned. Each agitation vat is provided with an iron grizzly, measuring 3 feet 3 inches by 9 feet, and having 1.25-inch openings, which is suspended over the vat, to one side of the center. The content of the car is dumped onto this grizzly and the portion that does not pass through of its own weight is trampled, or otherwise forced through, by one or two boys. For some time the material treated averaged from 20% to 25% of moisture, and in this condition was rather lumpy and extremely cohesive. During this period the agitation was very unsatisfactory and the percentage of extraction was consequently lower. A great deal of difficulty was experienced in discharging the vats, as the unagitated portion of the charge would remain in the pointed bottom of the vat as a tough, putty-like mass, after all the liquid portion had been discharged, and could only be washed out by means of a stream of solution or water under pressure. In such cases the most effective procedure was to attach a 2-inch hose to one of the valves on the solution line and sluice the material out under pressure furnished by the pump, into the launder leading to the corresponding decantation vat. The experience so far seems to have demonstrated that the best condition of the material, in order to obtain the most satisfactory results under the present practice, is to have the major portion of it, when dumped on the grizzly, run through of its own weight. In this state the slimes will usually carry from 30% to 35% of moisture. It is desirable that the percentage of moisture contained in the slimes when charged shall be as low as possible, compatible with satisfactory agitation, since it is obvious that the greater the percentage of moisture contained in the slimes the greater will be the mechanical consumption of cyanide resulting from the loss of cyanide present in the solution contained in the pulp as finally discharged, when the treatment is finished. It is true that a certain quantity of water must be added to counterbalance the loss of solution due to the fact that the discharged pulp carries a higher percentage of moisture than the slimes charged. It is true, however, that any addition of water that may thus be rendered necessary is most advantageously added to the charge in the form of a final wash of water. It seems that the complete drying of the slimes by some cheap, appropriate process, followed by the powdering of the dried slimes before charging them into the agitation vats, should be productive of improved commercial results. The net dry tonnage of slimes constituting a charge varies, but thus far a charge equivalent to about 15 tons of dry slimes gives more satisfactory results than does a heavier one. Before commencing to charge the slimes, about 35 tons of solution from the strong solution sump, usually of a strength between 0.12% and 0.15% of KCN, is pumped into the vat and the attached centrifugal pump started. From 75 to 100 pounds of slaked lime are then added and the charging of the slimes commenced. After the required quantity of slimes has been added, a sample of the material passing through the pump is taken, filtered and the clear solution titrated. The necessary quantity of cyanide to bring the solution up to the proper strength is then added. Experiments have been made with various strengths of solution in the agitation vats, the results thus far showing the use of 0.2% solution to give more satisfactory results than the use of a weaker solution. The cyanide is placed in perforated buckets or cans and suspended in the charge. It is found, however, that unless the receptacles containing the cyanide be frequently agitated about in the charge, the cyanide dissolves exceedingly slowly. It has been found on different occasions, when this point has been overlooked for any reason, that cyanide broken up in pieces about the size of 6-inch cubes and suspended in the charge at about 6 P. M. had not entirely dissolved by 6 A. M. of the next morning. The lesser the proportion of solution to solid matter present, the more noticeable is this tendency of the cyanide to dissolve very slowly. It is also noticed in this connection that the thicker the charge the slower is the action of the cyanide on the silver and gold contained in the slimes. During the agitation it is found best to keep the screen at the end of the suction pipe just as near the surface of the charge as possible, without allowing the entrance of air. By so doing, the material passing through the pump always contains a minimum quantity of solids, and the wear on the pump is consequently lessened. In addition to this, the movement or circulation within the charge is then the greatest, since the suction and discharge points are then the farthest separated. It is quite probable that a considerable portion of the heaviest and coarsest part of the material treated does not pass through the pump at all, as owing to its greater weight it may never be raised to the height of the suction screen. The agitation of the mass seems to depend chiefly on the fact that the discharge issuing from the drop pipe

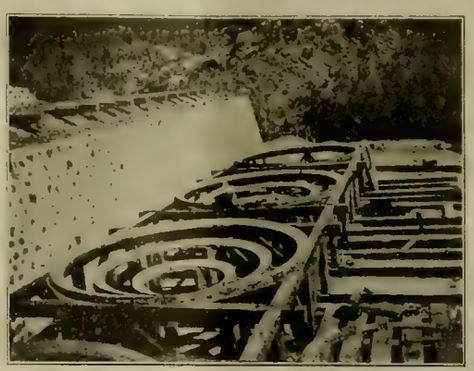

Fig. 8.—Timber Foundations Supporting Decantation Vats of Slime Plant.

Fig. 9.—Decantation Vats of Slime Plant in Course of Construction.

Fig. 10.—General Arrangement of Slime Plant, Palmarejo, Mexico.

Fig. 11.—Agitation Vats and Tops of the Decantation Vats.

*Trans. Amer. Inst. Min. Engrs.

tends to keep the point of the conical bottom free from any settled deposit of slimes, and the thickened material constituting the lower portion of the charge keeps constantly sliding down the inclined sides towards the bottom point. The product issuing from the discharge pipe, being drawn from the surface of the charge, must pass upwards through the entire mass above before it can again pass through the pump.

The percentage of solid matter contained in the material passing through the agitation pumps is determined from samples taken through the bibb-nosed pet-cock tapping the discharge pipe a few inches above the pump shell. The results usually show this percentage to be a little less than the percentage of solids contained in the charge as a whole. The average of a number of these samples shows that the pulp ordinarily passing through the pumps will carry about 25%, by weight, of solids.

A thorough oxygenation of the mass is found to be an essential feature, and becomes more necessary as the proportion of solid matter to solution present increases. At the commencement of operations, the small air cock, e (Fig. 5), was used to permit the continuous admittance of air to the suction pipe of the pump. This practice, however, was soon abandoned, because the agitation was seriously affected by it. The entrance of air into the suction pipe had a detrimental influence on the capacity of the pump, and though the reduction in capacity was not very marked—due to the fact that, owing to the manner in which the pumps are connected up with the vats, the suction side of the pump is, of course, continually under pressure from the pulp in the vat, and no suction on the part of the pump is necessary—nevertheless the effect was found to be injurious to the best agitation. Perhaps the chief trouble was due to the rapid rise to the surface of the imprisoned air immediately on being expelled from the discharge pipe, following closely the sides of the central drop pipe. The air bubbles, breaking on reaching the surface of the charge, caused a splendid surface movement that was easily mistaken for the thorough agitation of the entire mass. The current of pulp expelled from the discharge pipe appeared to follow the line of least resistance established by the rising bubbles of air, also rising towards the surface along the central drop pipe, without effecting a proper scouring of the bottom point of the vat. The present practice is to allow the entrance of a smaller quantity of air into the mass, through the small air cock l (Fig. 6), and the effect on the agitation is very much less detrimental. In addition to this, a certain small quantity of air will be drawn into the pump almost continuously through the stuffing boxes, which are seldom kept absolutely tight. The quantity of air added in this way is so small that it affects the agitation but little, if any.

For experimental purposes, one agitation vat was so connected that the suction of the pump drew directly from the bottom of the vat, while the discharge pipe entered through the side of the vat at a point about 6 feet from the top and terminated in a movable curved pipe which imparted a circular motion to the discharging pulp. Owing, doubtless, to the physical condition of the slimes charged, this method of pump connection was a failure, since the tendency to clog the suction at the bottom of the vat was very marked, and the charges so agitated never completely discharged from the vat of their own accord, but always left a more or less quantity of unagitated material remaining, which had to be subsequently sluiced out.

Ordinarily a charge is agitated in the vats from 40 to 44 hours, after which it is discharged into the corresponding decantation vat, where it is usually given a two days' treatment. Should the charge from the agitation vat not fill the decantation vat, enough precipitated solution is pumped up from the strong solution sump to fill it, and after agitation for half an hour, the charge is allowed to settle. Should the addition of this extra solution be unnecessary, the charge is not agitated, but allowed to settle as long as practicable, the clear supernatant solution being meanwhile decanted off. After the first settling and decantation, the vat is pumped full of weak, precipitated solution, which is usually of a strength approximating 0.1% of KCN per ton, and the charge is agitated for from 1.5 to 2 hours by means of the 3-inch centrifugal pump connected with the vat, about 25 pounds of slaked lime being added during the agitation. The pump is then stopped and an additional quantity of slaked lime, usually about 10 pounds, is sprinkled evenly over the top of the charge. After settling a few hours, the decantation pipe is lowered and the settling and decanting of clear solution continued as long as practicable. As many washes and decantations as possible within the time limit of the treatment are given in this manner. When permissible, the last wash given is of clear water, though in order to avoid too great an accumulation of stock solution a few of the charges have to be washed entirely with weak solution.

(TO BE CONTINUED.)

THE distance between levels of a mine should be determined by the size of the vein, or ore body, and its dip. If flat, below 35°, the levels should not be more than 60 to 75 feet apart. If steeply inclined they may be from 100 to 250 feet apart.

Placer Mining in Alaska.*

NUMBER IV.

TRACKS AND INCLINES. — The track and incline working at No. 8, Anvil Creek, Nome district, is fairly representative of open-cut work by this system. (See Fig. 7.) A special feature of the plant, however, is the removal of the overburden, in all 7 feet of muck and 5 feet of barren gravel, by hydraulicking. Seven hundred miner's inches are used through a giant, under a pressure of 200 feet obtained by pumping. After the barren ground has been removed the remaining gravel, averaging about 6 feet in depth, is shoveled into cars, pushed to the foot of an incline, elevated, and washed. The tailings are impounded on the claim, being scraped from the end of the sluices by two-horse scrapers.

At the time of observation six cars were in use, though this number can be varied to suit the conditions in hand. Two men are employed with each car. They take turns in shoving the car to the incline, one remaining at the bank with pick. The cars at this plant were of a capacity of 22½ cubic feet, though larger ones might be found more economical. From 250 to 300 cars are run up each ten-hour shift.

The material is lifted 30 feet to the mud box and there dumped by hand. A man is continually employed for this duty. He also watches large bowlders and prevents jamming in the flume. However, very few large stones are allowed to pass through, for in the work of excavation the larger rocks are piled at one side of the track.

One man is employed at the hoisting winch and does his own firing. Three 114-pound sacks of coal are consumed each shift. A 15 H. P. boiler is used with vertical engine, and a ⅜-inch cable hauls the cars.

The dump box is 24 feet long, 4 feet wide, and 3 feet high, and has a grade of 1 inch to 1 foot. Following this are 240 feet of boxes with a grade of ¾ inch to 1 foot. The boxes are 16 inches wide and 14 inches high, and are supplied with cast-iron grate riffles. These are 16 inches square and can be used either as Hungarian or longitudinal riffles. In washing, 125 miner's inches are used, all obtained by gravity from a claim above. After being used the water is caught in a retaining dam, settled, and carried by flume to a lower claim, where it is sold. Two two-horse scrapers are used to keep tailings clear, and all gravel is impounded by a brush dam upon the claim.

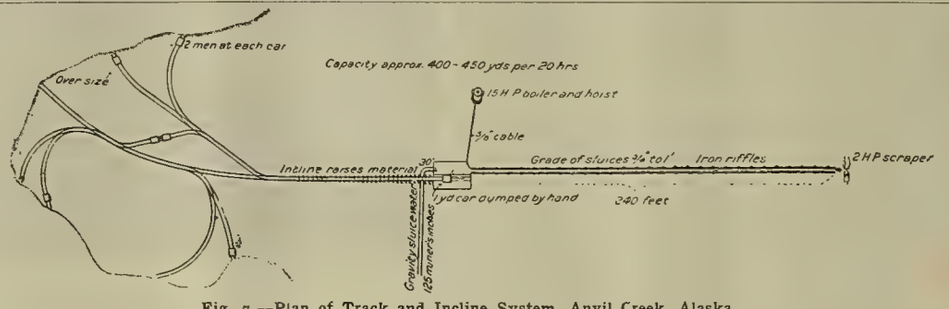
A little gold is caught in the entire string, though by far the greater proportion is retained in the mud box and that following. In the mud box a perforated iron sheet laid over the riffles aids the moving of material and prevents clogging. In the center of this sheet is placed a heavy iron plate which receives the heavy fall from the cars and saves the bottom of the mud box.

Bedrock on this claim is mica schist, though in places the pay is underlain by a stiff clay. The gold sinks in the broken schist about 2 feet, but not at all in the clay.

A bedrock drain, 250 feet long, has been cut nearly level, which is joined by small drains from various parts of the pit. Only about 15 miner's inches of water were running from the drain at the time of observation. Men are paid $5 a day, with board.

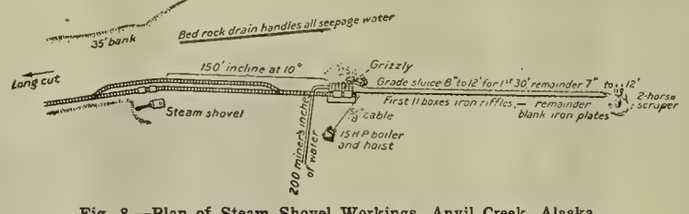
The advantages of the car-and-incline system are not especially pronounced. The method of stripping used in the above-described plant, or at any plant where water under pressure is available, can hardly be improved upon. Where the overburden is thawed or where frost is encountered only in spots, as in the claim under discussion, hydraulicking has been found the most economical and efficient means of removing material. The car system, however, has little of solid economic advantage to recommend it. In order to increase capacity more men must be employed to shovel. In this system an undue proportion of time is consumed in tramming the cars to the top of the incline. A mechanical system, such as derricking or steam scraping, has many advantages over the track-and-incline. In the Klondike, so far as could be learned, the track-and-incline system does not make so economical a showing as other methods of working open cut, although the opportunity for comparison of efficiency was limited.

THE STEAM SHOVEL.—When the ground exceeds 12 feet in depth and is unfrozen, certain conditions justify the installation of a mechanical excavator of large capacity, say 1000 cubic yards or more in twenty-four hours. It will seldom be found advisable to install so large and cumbersome a machine as the steam shovel in the creek diggings of Alaska, for the ground is rarely deep enough to justify the expense of installation. On bench diggings, however, where the pit can be drained by gravity, the steam shovel has a value which has probably been underestimated. The fact that water under pressure is difficult or impossible to obtain for the hydraulicking of benches raises the question whether these bench gravels cannot be excavated by other means. The value of the steam shovel lies in the fact that it performs for the earth worker that portion of his work which would otherwise be most expensive.



2 men at each car
Capacity approx. 400 - 450 yds per 20 hrs
Over size
15 H P boiler and hoist
⅜" cable
Grade of sluices ¾" to 1'
Iron riffles
2 H P scraper
Incline raises material 30'
1 yd car dumped by hand
240 feet
Gravity sluice made of 125 miner's inches

Fig. 7.—Plan of Track and Incline System, Anvil Creek, Alaska.



35' bank
Bed rock drain handles all seepage water
150' incline at 10°
Grizzly
Grade sluice 8" to 12" for 1st 30', remainder 7" to 12'
Lang cut
Steam shovel
First 11 boxes iron riffles,— remainder blank iron plates
2-horse scraper
⅜" cable
15 H P boiler and hoist
200 miner's inches of water

Fig 8.—Plan of Steam Shovel Workings, Anvil Creek, Alaska.

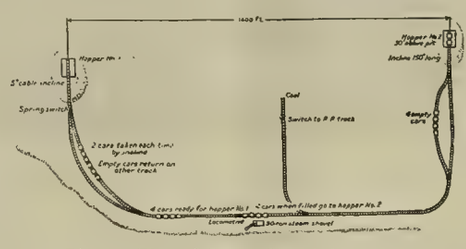


Fig. 9.—Plan of Steam Shovel Operations

The ground which the shovel is to move must possess certain favorable conditions. In the first place, it must be entirely free from permanent frost when the dipper lip of the excavator attacks it. If the ground holds a certain amount of permanent frost and this can be thawed by ground sluicing the muck off at a period far enough ahead, the shovel may still have a profitable field, but its operations are likely to be more expensive. Heavy gravel and bowlders are easily handled by the mechanical excavator. It is safe to say that no quality or state of the Alaska gravels makes them unfit to be dug by the dipper except the frozen condition.

The bedrock must be of sufficient softness to allow the dipper lip to dig far enough into it to recover all the gold; otherwise a gang of men will have to follow the shovel to clean bedrock, and a large part of the value of the shovel will be lost. In one attempt to operate with a steam shovel in the interior of Alaska it was found that as many men had to be employed in cleaning the bedrock as in the remainder of the plant.

A prime essential to success, as has been proved by experience, is that the washing plant shall be isolated, the gravel being conveyed from the dipper to the sluice by some form of tramming. If cars are used, they should be large—2 yards capacity, or even larger. Under ideal conditions the dipper will dump into cars which run by gravity to the hopper of the washing plant, the water being brought to the sluice also by gravity. The full cars would in this case carry the empties back to the pit. It is rarely possible, however, to find an auriferous gravel de-

*Bulletin 263 U. S. Geological Survey.

posit in which such eminently fit conditions exist for work. The tramming, even when it must be up an incline to a height of 35 feet above the pit floor, adds proportionately little to the expense, as will be seen by figures following. It is a common fault in all steam shovel operations that the shovel is ahead of the car discharge. A partly idle steam shovel, however, is not so serious a fault as idle men, since the shovel draws no pay.

As to capacity, it is likely that a 2-yard shovel, fitted with extra long boom and 1¼-yard dipper, will be found most economical. A 25-foot bank can be dug and caved. If the sluice and tramming capacity is 700 cubic yards a day, the shovel will easily supply the material if no frost is encountered.

The work done by a shovel on Anvil creek is considered satisfactory, though its installation is experimental, and a larger one is planned. The 25-ton shovel (¾-yard dipper) is working on an 18-foot face. It has not reached the bottom of the gravel, and must make another cut 7 feet lower vertically before all the pay is extracted. It is said that from July 23 to September 1, 1904, 25,000 cars of 1¼ cubic yards capacity were dug and moved to the sluice boxes at a working cost of 12 cents a yard. The low bench is sufficiently above the level of the present creek to permit the pit to be drained, the seepage water being handled by bedrock drain. The workings were visited a second time three weeks after the present cut was made. A complete section of the bank to bedrock is given below:

	Feet.
Muck	3
Fine gravel and sand	5
Fine subangular gravel	5
Large subangular schist and limestone fragments, stained with iron oxide, with a few bowlders up to 3 feet in diameter	15

The upper 3 feet of muck was ground sluiced; the remainder was moved by the steam shovel.

This frozen ground illustrates the peculiarly trying conditions with which the Alaska placer miner has frequently to deal. None of the ground encountered in 1904 was frozen. In the early part of the season of 1903, however, on account of the light snowfall during the preceding winter, the sides of a cut operated on were frozen to a depth of 8 feet and to a distance of 15 feet into the bank. This was annual and not permanent frost. Had the attempt been made to work the ground at that time with the shovel the operations would have been greatly delayed. In this plant, after the shovel had worked to a considerable distance from the bottom of the incline, the 1¼-yard cars, three in number, were trammed to the bottom of the incline by horses and hoisted to sluice by a 15 H. P. hoist. The tramming may be more cheaply accomplished, where there are several years' work ahead, by a small locomotive in the pit running to the bottom of the incline or, under favorable conditions, directly to the washing plant. Fig. 8 shows a plan of the operation under discussion.

The tramming system illustrated by Fig. 9, used at Galesburg, Ill., in a shale pit, is considered highly economical in steam shovel work. As may be seen, the locomotive occupies a position intermediate between the two trains of cars, which deliver two ways to the bottom of two inclines leading to the hoppers of the clay machines at each end of the pit. In placer operations, if conditions admit of dividing the water to two washing plants, this system is to be recommended, as it allows of rapid delivery of the cars from the shovel. In this plant the locomotive keeps twenty cars going, each of two yards capacity, tramming them alternately in trains of six and four, two ways to the ends of the pit, whence they are hauled two at a time to the hoppers. When empty they run down and are switched automatically to the empty tracks. The 90-ton shovel, of 5-yard dipper capacity but fitted with 2-yard dipper, is ahead of the capacity of the clay machines, but must be used, owing to the difficulty of digging the firm shale which composes the bank. The actual yardage moved, working nine hours a day, is 670, or at the rate of 1488 yards in twenty hours. It is estimated that this is less than one-half the amount that could be handled were the shovel digging loose gravel. As it now works, the shovel is digging only one-third the time.

The Transvaal Gold Mines.

NUMBER III—CONCLUDED.

Written for the MINING AND SCIENTIFIC PRESS by THEO. F. VAN WAGENEN, E. M.

Management expenses are abnormally high, mainly because the English Company Act compels a very elaborate system of accounting and auditing in all public corporations, and also because the written and unwritten laws and customs of the country have induced a very coventionalized way of doing business, the net result of which is that the staff of officials and clerks in every line of activity, and particularly in that of mining, is unreasonably large. This is well recognized in both London and at the goldfields, and efforts are being made to bring about changes, but the system is so deeply rooted, and English conservatism is so great, that it will be some time before improvements can be secured.

In spite of these drawbacks, production will not only continue but will increase. For the goldfield is a genuinely meritorious one, is of enormous extent, and the capital has been raised to develop and equip a very large part of it. These factors may be considered as definitely settled. The mines will be worked as long, at least, as actual costs can be recovered from them, and in many cases, if necessary, at a loss, in the hope of a change in the results. The output of metal from the camp will amount to nearly $90,000,000 during the current year, and will grow at the rate of not less than 5% per annum for many years to come. This means that between now and 1913 (for example) the Transvaal will add over $1,100,000,000 worth of gold to the existing world's stock of the metal, and will then be producing at the rate of nearly $140,000,000 per annum. By 1920 the annual output will have almost reached the enormous figure of $200,000,000, and its contribution of new gold since the close of the year 1904 will exceed a value of $2,300,000,000. As the existing stock at the present time in the shape of coin and bars is figured by statisticians at not over $11,000,000,000, the Transvaal alone, if these anticipations are realized, will be responsible for an addition of more than 20% during the next fifteen years, to say nothing of the increments that will come from the other gold fields of the world, and which will at least amount to twice as much or more. Just what is going to happen in international trade and commerce through this enormous expansion in the next few years in the mass of the only legal money metal, is hard to say.

The Transvaal is an ideal mining region in many respects, and particularly that part of it known as the Rand. There the altitude is over 6000 feet, and the climate superb. The American, accustomed to the extremes of temperature in all parts of his country, will revel in the very moderate range which the thermometer shows in Johannesburg. In June and July thin ice forms at night in exposed places, and in December and January it is uncomfortably hot in the sun during the middle of the day. But that is all. In no possible sense can the climate be considered even as sub-tropical, or one in which the white man cannot labor with the same continuity and vigor as in Europe and the United States.

At the end of 1904 there were 285 mining companies operating on the Rand whose combined capitalization amounted to $412,337,357. The gross output of gold in the district for the year was $76,523,481, and the dividends declared and paid totaled about $25,000,000, two-thirds of which came from the outcrop mines and the remainder from the first series of "Deeps." Thus, considering the whole field, a net profit of 6% on the gross capital was obtained. This is not a bad result, but of course is much below what a gold mining adventure is expected to yield, considering the assumed extra hazardous nature of the business. But further investigation displays the fact that only forty of the companies paid dividends in 1904, while the other 245, either because they had not yet reached the producing era or were not capable of it, yielded nothing at all to their shareholders. If we apportion the entire capitalization pro rata among all the corporations—which will be at least fair in the present calculation, for the most of the paying ones are the outcrop mines with comparatively small capitals—it appears that about $50,000,000 of the investment is paying about 50% per annum to its holders, while the remaining $362,000,000 is as yet unproductive. This is really a very fine showing, for of course most of the non-productive mines are in the developing era and are simply spending the capital that has been raised for their equipment and, one by one, will in the majority of cases and in due time reach the stage of production and profit.

It is necessary to admit, if one gives the great camp a fair and impartial study, that nearly all of the developing mines have good business prospects for becoming large producers and dividend payers. In all cases before shaft sinking has begun the ground has been well tested with the diamond drill, the reef has been located at a number of points and its value has been ascertained. There is much more certitude in operating on the Rand banket than is usually the case in the business of gold mining. And in any event, even if dividends do not quite come up to expectation, production will continue, so that the business world is bound to experience the stimulus of the new gold that will be poured into the channels of trade. Personally, however, my view is that the Rand will meet the expectations of all but the very wildest of the optimists.

It is a fact that the reef slowly but steadily loses its dip as it is followed downward into the earth, and there is every reason to believe that it ultimately becomes horizontal and even may show an upward trend. But it is not thought that it comes to the surface again, for the indications of extensive faulting of the formation to the northward are too numerous and positive to allow of such an outcome. As to the depth to which mining upon it can be prosecuted, there appears to be no insurmountable physical or mechanical obstacles short of 10,000 feet vertical, though unless the present range of costs in the items of labor and management are materially reduced, the ore from such depths, and a considerable way this side of it, assuming no decrease in the grade, will not pay for its extraction.

Market Place, Johannesburg, S. A

Headframe, Crown Reef Mine, Johannesburg, S. A.

THE PROSPECTOR.

The brown sugar-like mineral in the ore from the Mount Hope mine, El Dorado county, Cal., is quartz, which occurs in the form of rounded, sand-like grains.

The dark-colored rock samples from Cochrane, Ariz., are diabase, but considerably altered.

The mineral sample from Placerville, Cal., is platinum and iridium. These metals usually occur together in regions of serpentine rocks and peridotites.

The rocks from Keeler, Cal., are: No. 1, rhyolite; No. 2, rhyolite tuff; No. 3, mica schist; No. 4, limestone. The green mineral is chrysocolla (a silicate of copper).

The rock sample from Cochrane, Ariz., is a much altered dike rock. The rock now consists chiefly of quartz, kaolinized feldspar, chlorite and talc, with microscopic flakes of secondary mica. It was probably a granitic or dioritic rock originally. It is sheared and so much altered as to make positive identification impossible.

Gold Dredging in California.*

NUMBER III.

BUCKETS.—The buckets at Folsom, Oroville and Yuba vary in size from 3 cubic feet capacity up to 8½ cubic feet, and it is proposed now to build a dredger at Folsom with buckets of 13 cubic feet capacity. They vary considerably in shape, and in the material used, but some of the best are those that are made with a cast nickel steel bottom piece, with sheet steel hood and manganese steel lips, and reinforced cutting edges. If a comparison could be made as to the breakage and consequent extra cost between the earlier buckets made and those now being turned out, a great advance would be shown, and greater advances are possible. This is a matter for the consideration of the manufacturers and the engineers in charge of the plants.

As to the difference in cost of operating under favorable and similar conditions with the different sized buckets, it may be said that the cost for labor is nearly the same for the small as for the large dredger, and much smaller per cubic yard for the larger; that there is a proportionately smaller cost for power and for repairs. Management and all other expenses are reduced in the larger dredgers, provided, of course, that in their construction there is given, by the strengthening of the parts, as little loss by breakdowns. Then, it may be said, that the larger buckets will handle larger bowlders and so decrease the breakage in the bucket line. The parts being heavier, it is possible to dig harder ground. The increased yardage handled will mean a decrease in the interest cost on the original investment. As against this, it may be said that the first cost is much larger, and that better equipped repair shops are required.

The weakest portions of the bucket bottom are the eyes and the parts coming in contact with the manganese or nickel steel wearing plates of the upper and lower tumblers. As these wear there is an increase in danger of breakage, and it is to the manufacturers that we must look for remedies in this respect, by the addition of more metal to add strength and compensate for wear, by improvement in the character of the steel used, and by changes in the faces of the tumblers in order to give better bearing and reduce the strain. Simpler and stronger parts of the best materials must be used to remedy the present evils.

SPUDS AND HEAD LINES.—To keep the dredger in place, move it about, and hold it against the bank, there are two methods in use: (1) Two spuds, one of steel, and one of wood at the stern of the boat—the wooden spud being used when the steel spud is lifted and it is desired to "walk" the boat ahead. At the forward end of the boat are two steel-wire rope lines fastened to the shore to move the boat to right and left through an arc of a circle, and two at the stern. (2) Instead of spuds and lines, five lines are used—two at the stern, two forward, and one ahead to hold the boat against the bank.

In the lighter and softer ground in New Zealand, the guy method seems to be preferred, but in Oroville both methods are in vogue.

Where the surface of the ground is level, and the ground to be dug is soft and shallow, some of the dredger owners prefer the lines. An uneven surface of the ground, hard gravel or deep gravel makes the spuds preferable. Most of the largest operators in Oroville equip boats with both, but use the head line only in emergencies. When using guys only, the digging must be done only from the bottom; while with the spuds the bank may be cut in terraces, and this is sometimes preferable in deep ground.

In deep ground when cutting the bank by digging from the bottom up in terraces, or down, there is less danger of injury to the bucket line and cleaner lifting of all gravel if spuds are used. This means that there would be less loss of pay gravel caved down behind where the digger is working, and less loss of time and consequent less loss of capacity in yardage. However, several operators state that with a head line instead of spuds in digging deep ground, the dredger may be moved more quickly in case of heavy caving of the bank, and so save accidents. Then, again, the use of the head line gives an easier and more even distribution of the tailings, and, it is claimed, makes the sand pump unnecessary.

THE STACKER.—There are two types of stackers in use in California—one the ordinary belt conveyor, and the other an endless chain of buckets. Usually, the Bucyrus dredgers, and other makes except the Risdon, are equipped with belt conveyors, while the Risdon is equipped with bucket conveyors. The belt conveyor will not work at a higher grade than 18% or 20%, while the bucket conveyor works usually at 35°. The belt of the former must be renewed every six or nine months. This makes the cost of "repairs" considerably more than for the bucket conveyor. However, to offset this, there is considerably less loss of time with the belt conveyor from this cause, for practically the only wearing part is the belt, and when this wears out, a new one can be put in in a few hours. Some of the tables of loss of time and cost of repairs of conveyor give figures so that comparisons can be made, but hardly enough data have been kept to figure closely on the differences.

In New Zealand a number of dredgers equipped with centrifugal stackers are in use. It is claimed for them that the original cost is less, that the weight saves several tons on the boats, that the cost of repairs is less, and that the efficiency is as great as for the belt and bucket conveyors. However, none have been built in California and no definite data are at hand.

SAND PUMPS.—In order to prevent the filling up of the basin in which the dredger floats and consequent interference with its flotation, in many cases in Oroville it has been found necessary to pump the fine tailings that come from the sluice box up to the top of the rock pile made by the stacker. As this requires considerable power, it is discarded wherever possible. In deep ground with deep water, it is not required.

SCREENS, SLUICES, ETC.—The conditions that are most important to be considered in order to determine the kind of appliances to use in saving the values are: (1) Size of particles of gold; (2) Shape of the particles, whether nuggety or flaky; (3) Presence of clay; (4) Will the gold amalgamate readily? (5) Amount of black sand; (6) Amount of platinum; (7) Hardness of gravel.

Screens: Two kinds of screens are used in California—the shaking and the revolving. The purpose is to disintegrate the gravel and clay in order to permit the fine material, the values and water to pass through the holes along the length of the screen to the gold-saving tables or sluices below, and convey all coarse material to the stackers, to be carried to the dump piles. As to screens, two main questions must be determined: (a) Whether to use a revolving or a shaking screen; (b) Size of holes in the screen.

As to (a) the hardness of the gravel and the presence or absence of clay are main determining features. If the gravel is a clean wash, comparatively free from clay, such as that at Oroville and Folsom, the shaking screen is generally preferred to the revolving screen, mainly because the first cost and the cost of repairs are less. However, there are cases, even in these districts, when some hard pieces of gravel are not disintegrated and the values lost. In case there is any clay present, it will adhere to the gravel or pieces of bedrock, especially if blocky, or will "ball up" and so carry off the gold. In a shaking screen, boulders and larger pieces of bedrock will not be turned over so that the water jets will have free play. This is the case especially in such bedrock as most of that along the Yukon, which is often blocky, and carries much gold in clayey seams down to a depth of from 1 to 6 feet. Where the gravel is hard it has little opportunity to disintegrate in the length of the shaking screen. A revolving screen with flanges and rods across the screen will turn the material over and over, subjecting all sides of it to the force of the water from the jets, and will afford a sort of milling process by which the boulders and smaller stones are lifted up and thrown down on the lumps of gravel and clay.

Under the favorable conditions existing in the Sacramento valley districts the shaking screen is preferred for the following reasons: (1) The effective

A Modern California Gold Dredger.

*Bulletin 36, California State Mining Bureau.

screening surface is larger; (2) It is easier kept in repair, because the plates are small and conveniently replaced; (3) The gravel drops over a larger surface on the plates below, and so comes the better in contact with the quicksilver. Then the water from the jets playing down on the screen plays over a wider and thinner surface.

In some cases a combination of the revolving and shaking screens would be preferred. In this way two screenings could be had.

The revolving screen varies in diameter from 3½ feet and in length up to 24 feet. The shaking screen for a 5-foot bucket dredger is in some of the later dredgers built in two parts — the first part 7 feet wide and 16 feet long, and the second, or lower part, 7¾ feet wide and 16 feet long. This enables, of course, a much larger sluicing table space to be employed below the shaking screen.

The size of the holes in the screens will be determined by the size of the largest particles of gold. At Oroville and other districts in the Sacramento valley, where all the gold is fine, $\frac{5}{16}$ and $\frac{3}{8}$-inch holes are generally used. Where there is both coarse and fine gold it must be remembered that with the larger holes coarse material will have to be sluiced, a greater depth of water will be required in the sluices, and there will be a consequent greater loss of fine gold. To obviate this, it is suggested that smaller holes be used in the upper part of the screen and larger holes in the lower part, and that the finer and coarser material be run into separate sluices. It would not be necessary to have the larger holes in more than 4 feet, or even less, of the length of the screen.

Sluices: On the dredgers in the Sacramento valley districts, such as Oroville, Yuba and Folsom, the gold is saved on what are called gold-saving tables and a sluice running out astern of the dredgers where the tailings are dumped into the water. The area of these tables is for a 5-foot dredger with shaking screen about 750 square feet and for the sluices about 300 square feet, and somewhat less with revolving screens. This area is somewhat less for the smaller dredgers and more for dredgers of larger capacity. As it is, generally speaking, all the surface possible is made, and it is limited, of course, to the size of the boat. There can be no question but that much of the finer gold is lost. How much this may be has not been determined, for, no matter how careful the rocking and panning of the drill samples, the finest gold is not saved.

It may be said that if some of the finest gold saved at Oroville were shaken up in a bottle of clear water it will take two hours' time to settle again. Therefore, neither panning, nor rocking, nor any of the present gold-saving devices can save all the gold. One of the best informed men at Oroville, who has been in the industry since the beginning, says that, with the improvements that may in time be made in the gold-saving appliances, it would be possible to save more gold in the dredgers than could be shown by the most careful and exact sampling with pans and rockers.

In most cases at Oroville and Folsom the tailings are sampled in order to determine how much gold is being lost. But this sampling is of no value except to show that the sluice boxes and tables save a large per cent of what could be found by panning or rocking. In other words, very little is found in the tailings, and in most cases practically none at all, by panning or rocking.

The quantity of fine gold which goes off in the water should be determined by test, and if it amounts to as much as seems probable, there should be devised a scheme, in connection with the sand pump, for an auxiliary saving appliance that would enable a larger proportion of the finest gold to settle. The amount of extra power that would be required and the cost of extra equipment need not be much. Of course, the larger the dredger, the greater the opportunity to save larger proportions of the gold now being lost.

(TO BE CONTINUED.)

Proposed Prize Competition.

The international labor office, of Basel, Switzerland, has invited an international prize competition for the prevention of lead poisoning and want to make the fact known to every one engaged in mining, milling, smelting and refining lead. The competition is proposed subject to certain conditions. Among the prizes offered are one prize of $1200 for the best treatise on the prevention of lead poisoning in the operation of mining and milling lead ores or ores containing lead and one prize of $2400 for the best treatise on the prevention of lead poisoning in smelting and refining works.

The papers may be written either in English, French, or German. Already printed books cannot be taken into consideration by the jury. The ready manuscripts must be put in an envelope bearing only a motto, and lodged with the international labor office at Basel on or before December 31, 1905. The full name and address of the author should be stated under a separate sealed cover bearing on its outside the same motto as above. Contributions arriving later than December 31, 1905, will be excluded from the competition.

A Noted Mexican Gold Mine.

The Rosario mine at Guadalupe y Calvo is in the southwestern corner of the State of Chihuahua, Mex. The great gold-bearing veins of the district occur in andesite. The Rosario is one of the largest gold veins in the world, and is from 60 to 150 feet or more in width. The hanging wall has been eroded to considerable depth below the outcrop, so that the vein forms a great wall facing the valley. The topography and general appearance of the mine on the surface is well illustrated in the accompanying engraving.

The Rosario Mine, at Guadalupe y Calvo, Chihuahua, Mexico.

The main open cut on this great vein is nearly 2000 feet in length, and about 130 feet wide. There have been four large shoots of payable ore worked. These were separated by masses of low-grade quartz. This latter material has been piled up in large dumps about the vicinity of the mine. This low-grade ore has lain on these dumps for many years and has mostly been sorted and picked over by the villagers, but, notwithstanding this, it is said that what now remains contains payable values in gold when worked by the cyanide process, assaying about one-half ounce of gold per ton. The natives say the vein was discovered in 1835 by an Indian, who made its whereabouts known to miners working at El Refugio mine, about 30 miles to the southward.

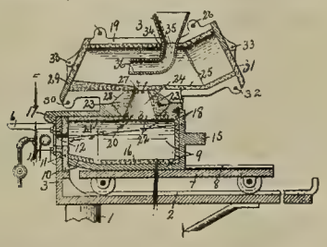
When the extent and value of the Rosario and the surrounding district became known, a stampede to the new district resulted and in a very short time 2000 people had settled about the mine. The Rosario has had many owners and the yield became so large at one period that the Government built a mint at Guadalupe y Calvo. The great vein is credited with a production of over $40,000,000. It is now owned and operated by American capital, and is again an active producer.

Mining and Metallurgical Patents.

PATENTS ISSUED AUGUST 15, 1905.

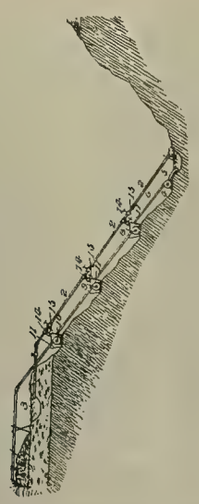
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

REVERBERATORY FURNACE.—No. 797,352; A. M. Gaylord, Auburn, N. Y.



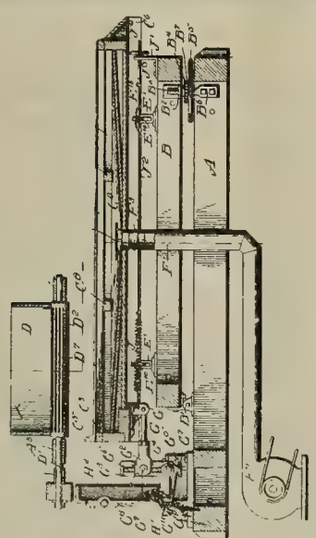
Furnace comprising two chambers, one above the other, and connected by vertical passage, lower chamber having fuel inlet and upper chamber having inlet for material to be melted, upper chamber having opposite ends provided with closures, each of which is horizontally divided to form lower and upper sections, which are hinged together at meeting edges, whereby upper section may be swung downwardly upon lower section.

MINING APPARATUS.—No. 797,068; A. McDougall, Duluth, Minn.



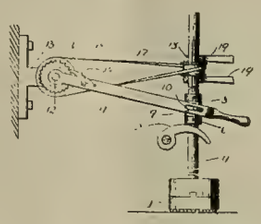
Mining apparatus comprising pump, pipe delivering water to and mixing it with ore or other material, inlet of pump in communication with mixed water and material, outlet of pump delivering mixed water and material to dump pile, reservoir in which water is collected by seepage from dump pile, aforesaid pipe in communication with and receiving supply from reservoir.

DRY CONCENTRATING TABLE.—No. 797,239; H. M. Sutton, W. L. Steele and E. G. Steele, Dallas, Tex.



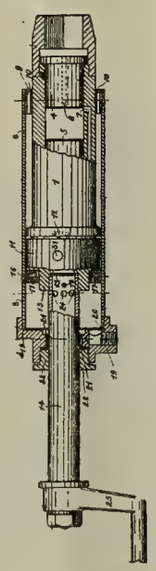
Combination of inclined pervious floor, having surface provided with longitudinally disposed riffles, means for maintaining successive zones of separated material, and means for maintaining beneath floor uniform upward pressure of air through pervious floor and material upon it.

STAMP MILL.—No. 797,202; C. J. Hodge, Houghton, Mich.



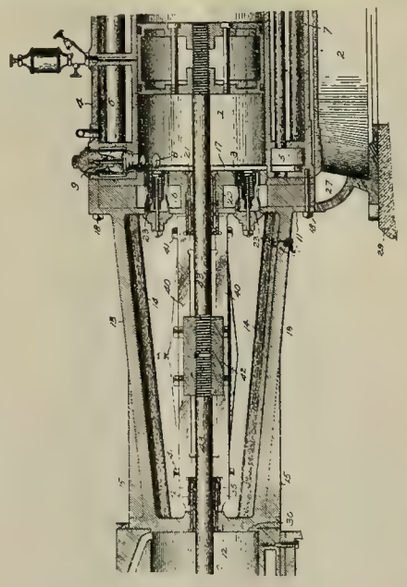
In stamp mill, combination of stamp shoe having flat lower surface provided with continuous corrugations extending throughout length of shoe, flat surface arranged in horizontal plane, upon which shoe is adapted to stamp and means for raising and lowering shoe bodily away from latter surface and imparting rotary step-by-step movement thereto while it is entirely clear or elevated from surface upon which it stamps.

ROCK DRILL OR ROCK DRILLING MACHINE.—No. 797,111; H. Hellman and L. C. Bayles, Johannesburg, Transvaal.



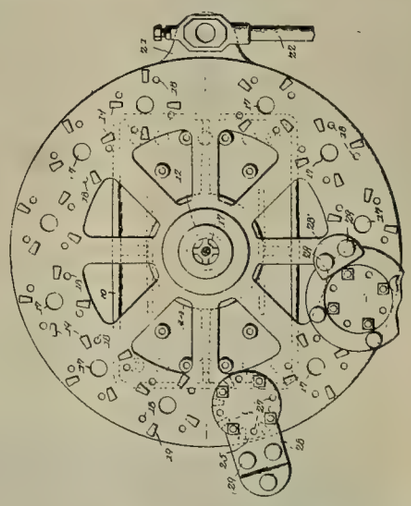
In rock drilling machine or engine, in combination, power cylinder carrying percussive apparatus and drilling bit or boring tool, casing surrounding cylinder, packing located at rear of cylinder forming air-tight joint with interior of casing, pipe attached to rear end of cylinder formed with holes placing casing in communication with interior of cylinder, cover fitted on rear end of casing formed with inlet through which actuating fluid enters casing, cover serving as guide or support for pipe, and means for rotating power cylinder and bit or tool.

COMBINED FRONT CYLINDER HEAD AND CROSS HEAD SUPPORTING FRAME FOR STEAM AND POWER AIR COMPRESSORS.—No. 797,519; J. G. Leyner, Denver, Colo.



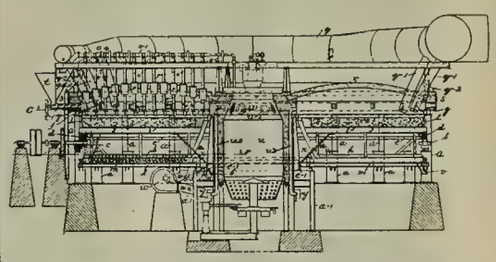
Device of character described consisting of integral casting comprising pair of suitably constructed and oppositely arranged cylinder heads which are connected by brace bars, holes through cylinder heads in axial alignment with each other, and lugs upon opposite sides of each cylinder head, and guideways connecting lugs on one cylinder head with those on other cylinder head.

OIL WELL PUMPING RIG.—No. 797,421; S. F. Field, Findlay, Ohio.



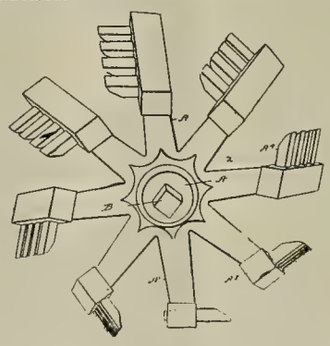
In oil well pumping rig for transmission of power from central source to plurality of pumps, crank disk having annular series of pin-receiving openings, set of lugs grouped around each opening, lugs of each set being correspondingly disposed throughout entire series of sets, crank disk being further provided with plurality of equidistantly spaced bolt-receiving openings grouped around each pin-receiving opening, wristpin-carrying block having central pin adapted to any one of pin-receiving openings, and being provided with recesses for reception of lugs, recesses being equidistantly spaced to permit circumferential adjustment of block, and bolts for securing block in adjusted position.

ORE ROASTING FURNACE.—No. 797,003; H. C. Holthoff, Milwaukee, Wis.



In ore roasting furnace combination of central combustion chamber, roasting chamber having annular floor or hearth communicating on inner side with upper part of combustion chamber through rapidly disposed openings or passages distributed around it, exit pipe or flue connected with outer part of roasting chamber by branches distributed around it, and means for gradually moving ore across floor or hearth.

SUCTION DREDGER.—No. 797,109; M. C. Harris, San Francisco.

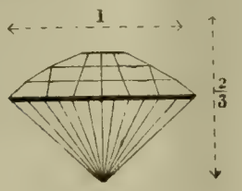


Cutter head for suction dredgers, consisting of hub; arms radiating therefrom; socket heads on arms approximately parallel with line of driving shaft, and converging to inclosure, series of rolling elements, plurality of obstructing and deflecting elements arranged upon surface of central inclosure, against which rolling elements are adapted to impinge, and pivoted member operable by hand for diverting rolling elements into different receiving pens.

Something of the Diamond Industry.

The greater number of diamonds mined are sent to Antwerp, Belgium, for cutting and valuation. British Consul General Hertslet has contributed some interesting information concerning the cutting of a diamond to the London Mining Journal, from which the following is taken:

The cutting of a brilliant is undoubtedly the process which best shows forth the lights and reflections contained in a diamond. A perfectly formed brilliant should have the proportions in depth from the upper surface or summit to the lower point called the pyramid or pavilion of two-thirds of the diameter of the stone at the belt or middle, as is shown in the illustration. The diagram, however, refers to the correct dimensions of a brilliant only, and must not be taken as illustrating the correct formation of the cut facets of a diamond.



The Brilliant Diamond.

The summit or crown of a brilliant should have thirty-two facets, and in addition one large central facet called the table. From the side of the pyramid it should have twenty-four facets and one small facet at the lower point called in this country the "collette," making in all fifty-eight facets, and not, as has been sometimes stated, sixty-four facets. These facets should be calculated, divided, and regularly cut in such a manner that those cut on the pavilion of a diamond may reflect the light on to the facets cut on the summit, and vice versa, thus showing forth in as high a degree as possible the sparkle and glitter of the gem.

All diamonds are cut in a series of stars, one being formed over the other. On looking through the flat surface or table of a properly cut brilliant the "colette" or lowest point should appear to be directly in the center of the table. In the regular cutting of these facets depends the whole beauty of the diamond, and in their formation lies the secret and difficulty of the diamond trade.

The rose is a more usual form of cutting diamonds of less value and thinner formation, and is cut with one large facet at the base and twenty-four triangular facets on the summit. The thicker stones cut in this manner with twenty-four facets are called on the continent "roses couronnees." Those which are only cut with twelve or six facets are known by the name of "roses d'Anvers," and form one of the chief specialties of Antwerp. They are not, however, cut in this manner unless the stones are of insufficient thickness to allow of their being cut in the form of "roses couronnees."

In addition to the two regular modes of diamond cutting described above, which are almost universally adopted, there are several other ways, but long experience has proved that the brilliant and the rose, or regular formation, show forth the sparkle and light contained in the diamond in a greater degree of brilliancy than other methods of cutting.

The quality and value of a diamond may be roughly determined by examining it against the light. In a stone of inferior value there appear to be many lines or scratches, whereas the more perfect stone is recognized by its purity and lack of marks in the grain, and also by its regularity of formation.

CAISSON DISEASE was the subject of a suit for damages and a legal decision relating to employers' liability in London recently, says the Engineering News. A workman had been employed in compressed air work on the tunnel being built for the Charing Cross, Euston & Hampstead Railway. The pressure in the work is normally fifteen pounds, but at times it was increased to twenty-five pounds. After working in the tunnel for eight months the workman became ill with what was claimed to be caisson disease or "bends." He sued his employers for damages, claiming that the attack was an accident resulting from his employment. The defendants contended that the disease, if caisson disease, was of gradual development and not a sudden happening, hence could not be classed as an accident. The court held that the plaintiff had not suffered from an accident which would entitle him to compensation, and nonsuited him.

IN setting up a wooden tank, lay the bottom on the prepared sills first and then set up the staves in their regular order. Usually the manufacturers number each stave and bottom piece, as the tanks are set up by the makers. The bottom hoops are put on first, and the hoops are also tightened from the bottom upwards.

MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

Although mica has been found in commercial sizes in about one-third of the States and Territories, it has been mined the past year only in North Carolina, New Hampshire, Colorado, New Mexico, California, Georgia, South Dakota and Idaho, which are named in the order of their importance as mica producers. The total quantity of sheet or plate mica produced in this country during 1904, as computed by J. H. Pratt of the United States Geological Survey, was 668,358 pounds, valued at $109,462, an increase of 48,758 pounds in quantity but a decrease of $8,626 in value, as compared with a production of 619,600 pounds, valued at $118,088, in 1903. It appears that in 1903 and 1904 the production was nearly 300,000 pounds greater than in 1901 and 1902. This large increase in the production of sheet mica during the last two years is due to the very large quantity of small sized disks and rectangular sheets of mica that have been prepared for electrical purposes. The production of scrap mica during 1904 amounted to 1096 short tons, valued at $10,854, as against 695 short tons, valued at $6460, in 1903. During 1903, however, there were also reported 964 short tons, valued at $18,580, which were sold in the rough blocks as produced. This probably made at least 800 tons of scrap mica, so that the actual production of scrap mica in 1903 was greater than in 1904. Of the 1904 production, 610,121 pounds of sheet mica, valued at $100,724, and 200 short tons of scrap mica, valued at $2000, were produced in North Carolina. This was over nine-tenths of the total production of the United States in 1904.

The total production of gypsum in the United States during 1904 is estimated by G. P. Grimsley, in a recent United States Geological Survey report, as 940,917 short tons, valued at $2,784,325. Of this quantity 56,137 tons were crude rock, 70,167 tons land plaster, 274,672 tons plaster of Paris and 390,668 tons wall plaster. Gypsum is quarried and calcined in the following seventeen States and Territories, named in order of their importance as producers: Michigan, New York, Iowa, Texas, Oklahoma, Ohio, Kansas, Wyoming, Colorado, Utah, Virginia, California, South Dakota, Nevada, Montana, Oregon and New Mexico. A number of new calcining gypsum plants have been established in Iowa, Oklahoma, Colorado, California and Oregon.

ALASKA.

It is understood that smelting operations are to be commenced in October at the smelter of the Alaska S. & R. Co., erected for that company by Paul Johnson at Hadley, Prince of Wales island, southeastern Alaska.

United States Assayer Fred Wing, in charge of the Seattle assay office, states that his estimate of the gold output of Nome for the season of 1904 was $10,000,000. This amount will be the record for Nome and will exceed the output of last year by $3,000,000. Mr. Wing bases his estimate on the amount of gold which has been sent out of Nome so far this year and on the private advices which he has received from assayers and others. The large amount of machinery and ditching material which has been placed in operation at Nome and other localities on the Seward peninsula this year is responsible for the increase in the gold output.

In describing the Fairhaven gold placers, Seward Peninsula, Alaska, in a recent report of the United States Geological Survey, F. H. Moffit says that the total production of the Kotzebue gold field for the three years during which mining operations have been carried on is probably not far from $415,000. Of this amount Candle creek alone has turned out over three-fourths. The gold field immediately south of Kotzebue sound is divided naturally into three minor fields, defined by the watersheds separating the drainage basins of Inmachuk, Kugruk and Kiwalik rivers. The streams in the Inmachuk river valley, including the south fork, or Pinnell river, which up to the present time have been gold producers, are few in number and as yet only partly developed. Old Glory and Hannum creeks, with two or three small tributaries, are the chief ones besides the Inmachuk and the lower part of Pinnell river. Hannum creek joins Inmachuk river 2½ miles west of Record. The stream, which is about 9 miles long, occupies a deep canyon-like valley, which in a few places expands for stretches of ½ mile or less into a level floor 600 to 800 feet in width. The valley is cut into a series of schists and shales interstratified with occasional thin limestone beds, and is surrounded by a capping of lava of no great thickness. The schists and slates of the valley slopes are generally covered by the debris from the overlying lava, so that outcrops are not plentiful. The gold is unevenly distributed over the bedrock, and on only one claim had anything like a continuous pay streak been exposed. Here the valuable gravel deposits had a thickness of from 6 inches to 4 feet and a width approaching 100 feet. Besides the gold, the heavy concentrates from the sluice boxes show a large number of rounded and polished pebbles of hematite, some pyrite, and a small quantity of galena. Black sand is not found with the gold, since magnetite occurs in very small quantity. Gray sand or finely ground pyrite appears constantly in the pan, and larger pieces up to 2 or more inches in diameter are not infrequent. The best gold values are taken from the bedrock, which is usually a blue clay resulting from the decomposition of the underlying schists. The gold is heavy and black and is said to assay $18 to the ounce when cleaned. Nuggets worth $2.50 are not uncommon, but no very large ones have yet been found. Not more than eight or nine of the forty-five claims which have been staked on Hannum creek, and extend from the mouth of the stream at No. 20 below Discovery to the source at No. 25 above Discovery, were being worked at any time during the season of 1903. No development work of consequence has been undertaken below Discovery at the mouth of Collins creek nor above the mouth of Cunningham creek. Between these points the gold is coarser and the grade of the stream sufficient to permit the use of bedrock drains, so that pumps are not required. Toward the mouth of Hannum creek the grade decreases noticeably and the gold becomes finer and brighter in character. Although there is said to be sufficient water at all times for sluicing purposes, the work so far done can hardly be considered sufficient to determine the future of the creek. The largest tributary to Hannum creek is Cunningham creek, 2 miles long, which joins the larger stream 7 miles from its mouth. Like Hannum creek it flows over a schist bedrock. The valley is narrow and V-shaped and its sides are capped through much of their length by the shattered outcrops of the lava flow. The gravels are schist and vein quartz, with a small percentage of limestone at the lower end. The Cunningham gold is coarser than that of Hannum creek, but has never been found in large amount. Collins creek joins Hannum creek at Discovery, but has not yet been much prospected. The presence of valuable gold fields south of Kotzebue sound was first demonstrated on the creek known as Old Glory. This stream rises in the limestone area northwest of Asses Ears, follows an east-northeast direction for 6 miles, and reaches Pinnell river 1½ mile south of the new mining camp of Record. The lower 4 miles of this course is directly across the bedding and cleavage of the schists, which occur to the east of the limestone area just mentioned. Quartz lenses and stringers appear in all the schist outcrops, and angular blocks of vein quartz strewn along the hilltops have now and then furnished locations for quartz ledge claims. The cleavage dips quite constantly toward the northeast, so that the waters, in carving out the valley, impinged against the upturned edges of the inclined schist slabs, which acted like the riffles in a sluice box in concentrating the gold. This relation of stream course to cleavage may account also for the presence of the broad, rounded basins, or "pot holes," as they are called by the miners, which occur in the bedrock of the channel and are a source of some difficulty in the operation of mining. Both pyrite and hematite are found in the sluice boxes. As assays showing tin are reported, a careful examination of tailings from the sluice boxes was made at two or three places where work was being carried on, to establish, if possible, the truth of this report. None was found, but later information was received from Cabell Whitehead, of the Alaska Banking & Safe Deposit Co., that 27 ounces of metallic tin were obtained from gold brought to the bank from Old Glory creek, the metal occurring in the form of fine cassiterite grains, which, because of their weight, remained in the pan with the gold. The gold from Old Glory is heavy and black; it occurs irregularly on bedrock along the channel, but at no place on the stream can a well defined pay streak be shown. The smaller "pot holes" are said to be quite rich and to carry the best values on the rim, the larger basins returning a smaller profit to the miners. These pot holes are more difficult to work than are the other gravels, since it is necessary to shut out the water from the main channel and to keep the holes pumped out, and such work is not required where a bedrock drain can be used, as is generally the case. Drains and ditches for sluicing purposes are occasionally made by simply removing the moss and allowing the water to melt its own channel through the ice bed beneath. There is plenty of water for the requirements of the sluice boxes at all times with the exception of a week or two at the end of the season, during which there has been less than the usual amount of rain. Nelson Gulch leads down from a broad, low saddle in the divide between Old Glory and Inmachuk. Not much sluicing has been done on Nelson gulch since the early part of the season (1903), owing to the scarcity of water. It was expected, however, that this difficulty would be removed by the completion of a ditch more than a mile long which was being dug to bring water from a higher level on Old Glory. The gold is brighter than that of Old Glory, is rough and angular, and contains considerable quartz, and evidently has not traveled far from its original source. With the magnet a few grains of black sand may be found associated with a much larger amount of pyrite and some ruby sand. American creek is the largest tributary of Old Glory and heads up toward the north side of the Asses Ears. The gold is brighter than the other gold of the vicinity, but has never been found in quantity to encourage the prospector much. Candle creek of the Kotzebue field has given rise to the largest mining camp in the northern part of the Seward peninsula, and has yielded more than three times as much as the combined output of all the other creeks. From headwaters to the mouth, a distance of 16 miles, every foot of the ground has been staked, though not prospected, and some sixty-six claims have been recorded at Candle. Candle creek heads in the main divide between the north and south drainages of the peninsula. It follows a course nearly north-northeast and joins Kiwalik river at Candle, 6 miles above the head of Spafarief bay and 9 miles south of the sand spit on which the town of Kiwalik is situated. The stream occupies a broad, shallow valley, with sides sloping so gently that water does not drain off as readily as in the other valleys of the field, and in consequence traveling is more difficult. The lava rim is not so conspicuous here as on Inmachuk and Kugruk rivers, but its presence is made known by fragments in the gravel and on the hill slopes and by occasional outcrops. Exposures of the schist are rare, except where uncovered by the miners. Thin limestone beds are not unusual in the schists, and a small area of light-colored gneissoid rock is found on Potato creek. No pay streak is known on Candle creek, and the gold is, as the miners say, "spotted" or irregularly distributed on the bed. The presence of rich gravels just below the mouths of the tributaries from the west leads to the general belief among the miners that the gold comes from the country west of Candle creek, and in consequence only on that side have the bench claims had much attention. Black sand is unknown in the clean ups; pyrite and a few small pieces of rutile which occasionally have been mistaken by the miners for tin ore are heavy minerals associated with the gold; it is not considered a favorable sign when the iron stones fail.

Work on this creek has been carried on under many difficulties. Although more easily reached than many of the other Alaskan fields, the short season, combined with the high freight rates and great cost of fuel and supplies, has had the effect of retarding considerably the development of the region. In addition to these disadvantages, the cost of mining is increased by the low grade of the stream and the necessary use of the pump, and on some claims by lack of water for sluicing during a large part of a season already too short.

ARIZONA.

Cochise County.

(Special Correspondence).—Monazite is being shipped from Johnson, in the Dragoon mountains. It is found associated with the wolframite which Owen Smith and others has been shipping.

Johnson, Aug. 28.

Gila County.

High-grade sulphide ore is said to have been struck in the property of the Con. M. & D. Co., 7 miles west of Globe. The shaft is to be sunk to a depth of 150 feet.

Graham County.

At the Polaris mine, near Clifton, L. F. Sweeting is getting ready to resume development work.

Mohave County.

Thomas Murphy, R. J. Penberthy and George Ayers have taken a lease on the American Flag mine, 15 miles east of Kingman, and have begun work. The mine is opened by tunnel to a depth of 700 feet. —— The Vivian M. Co. has been incorporated, with J. A. Graves of Los Angeles as president and Thomas Ewing general manager. The properties are in the San Francisco district, near Vivian. A new mill will soon be put in, as well as a new hoist, air compressor and machine drills.

CALIFORNIA.

According to a recent report of the United States Geological Survey, Spain (long the world's leading producer of quicksilver) is now second to the United States. The output of quicksilver in the United States during 1904 was 34,570 flasks, valued at $1,503,795. Up to June 1, 1904, these flasks held 76½ pounds each; since then they have contained 75 pounds each. The production of 1904 was a decrease from that of 1903, which amounted to 35,620 flasks, valued at $1,544,934. All the quicksilver produced in this country comes from Texas and California. The production of quicksilver in Texas increased in quantity from 5029 flasks in 1903 to 5336 flasks in 1904, a gain of 307 flasks, and increased in value from $211,218 in 1903 to $232,116 in 1904, a gain of $20,898. The quicksilver production in California amounted to 29,217 flasks, valued at $1,270,940, as against 30,526 flasks, valued at $1,330,916 in 1903, a loss in quantity of 1309 flasks and in value of $59,976. The average price for quicksilver per flask in San Francisco was $44.10 in 1902, $45.29 in 1903 and $43.50 in 1904. The value of quicksilver imported into the United States in 1904 was $1405, whereas 16,351 flasks, valued at $650,076, were exported from San Francisco alone, mostly to China, Mexico and Japan, while the total exportation amounted to 21,064 flasks, worth $847,108. The greater part of the world's consumption of quicksilver is satisfied by the older mines. Besides the famous Almaden mines, worked by the Rothschilds under a renewal Government agreement for ten years from 1900, there are commercial deposits in the provinces of Almeria, Granada and Oviedo. Spanish quicksilver usually sells in London at 1 shilling per flask higher than the Italian metal. This difference is partly explained by the Spanish export tax of 540 pesetas per 100 kilos, imposed in 1898 as a result of the Spanish-American war. As the Italian output from the mines near Monte Auriate, Tuscany, is not large, any variation in the price of other brands would not influence this market appreciably. The Idria mines in Austria rank third in the list of producers and, although they have been worked for 412 years, their ore reserves are estimated to last forty or fifty years longer at the present rate of mining. Germany showed an increased consumption of quicksilver in 1904 by importing 1,522,964 pounds, and re-exporting only 94,772 pounds. Russia has enlarged the output of its mines in the Ekaterinoslav district, which are worked by A. Auerbach & Co. An appreciable quantity of quicksilver is exported annually from Russia to Hamburg, Germany. In Mexico the great activity in the gold and silver mines has given an impetus to the quicksilver industry, especially in the Guadalcazar district, in San Luis Potosi, and at Huitzoco, in Guerrero. Other deposits are at Ranas, in Queretaro, and at Batuco in Sonora. Quicksilver occurs also at Yulgibar, in New South Wales; at Huancavelica, in Peru; at Taghit, in Algeria; in Japan; in Germany; and near Akluri, in Turkey.

Amador County.

Near Amador City the Fremont shaft is to be sunk to the 1300-foot level and connected by a drift with the 1500-foot level of the Gover shaft. The mill is running full capacity.

At the Markley mine, 4 miles northeast of Volcano, fifteen men are grading for a 10-stamp mill. The dump is to be worked first.——It is reported that the soapstone deposit on the Bean place, east of Sutter Creek, is to be developed by Dr. Bishop of Sutter Creek.——The new 10-stamp mill at the Newman mine, on the Mokelumne river near the West Point bridge, has been started.

Calaveras County.

The Chapman gravel mine, near San Andreas, has been bonded to L. C. Hunter, who intends to open it up. This property is a consolidation of several interests. The channel is opened at both the upper and lower ends of the property and good values are known to exist at both ends.

El Dorado County.

(Special Correspondence).—The Crusader mine, at El Dorado, has been purchased by W. P. Frick and Seymour Hill. They have commenced development work, and the machinery is being received and placed in position on the property.

El Dorado, Aug. 29.

Those interested in the Rio Vista copper mine, near Fairplay, have been investigating a new electric process of concentrating their ore.——The Larkin property, south of Placerville, is being operated under bond.——The H. L. Robinson gravel beds, between Smith's Flat and the Five Mile House, near Placerville are to be prospected under a bond. They are owned by W. C. Green of Georgetown. C. S. Older has taken the bond.——A new hoist has been put in at the Koppikus mine, near Georgetown.——Ten additional stamps are to be added to the Pyramid mill, near Shingle Springs, making 25 in all.——A new engine and boiler are being put in at the Red Raven mine, near Shingle Springs.

Madera County.

(Special Correspondence).—There is unusual activity in the mining section of the high Sierras in this county the present season. Iron and copper deposits which have been known for years past, and which have been located and relocated many times over, have again been taken up and considerable development done. In the same region, east and southeast of Mount Raymond and south of Yosemite valley, there are gold, silver, copper, lead, zinc and iron deposits of considerable extent. The most extensive of the latter are those in what is known as the Minarets district, 75 miles northeast of the city of Fresno. A large number of locations has been made. The ores outcrop in great masses of hematite and magnetite. Most of the ores contain a little gold and silver. Near the iron mines is found siliceous silver ores. The entire district is heavily mineralized and only requires convenient and less expensive transportation to become producers. At Texas Flat, near Coarse Gold, the gold mines are in operation, after a long period of idleness.

O'Neals, Aug. 28.

Nevada County.

W. J. Morris, the agent of the American Smelting & Refining Co., which is operating the Selby smelter at Vallejo Junction, has purchased from the Pioneer Reduction Works, near Nevada City, the sulphuret tailings that accumulated through years of operations at the old works. The local company is not in a position to work these tailings as closely as the Selby company, and the latter also desires it as flux in the treatment of ores and sulphurets.——The work of opening up the Wright & Bailey mine at North San Juan has commenced under the direction of Manager Crane. It is said that a mill will be put up during the fall.

San Bernardino County.

(Special Correspondence).—On the Sunrise mine of Beck & Body, in Kingston mountain, two ore shoots have been opened up and drifting is under way.

Sandy, Nev., Aug. 29.

The Arizona-Mexican M. & S. Co. expects to have its plant at Needles in operation within ninety days. The preliminary details have been completed and the property of the Fletcher S. Co. transferred to L. D. Gotshall, managing director of the new company, who will make changes that will amount to practically building a new plant. The equipment will include an automatic mechanical roasting furnace and sampling works.

Shasta County.

The new smelter of the Mammoth Copper Co. at Kennet is now almost completed and ready to go into operation. From the time the ore enters the smelter from the mill, 2½ miles distant, the process is entirely automatic. The ore is conveyed to the smelter from the mine by a system of trams, which present a novel feature. The grade from the mine entrance to the millsite is so steep — the two levels being 2219 feet apart — that two tramways are used for covering the entire distance. Midway between mine and mill a transfer station is placed. The grade from the mine to the station is 22%. This necessarily generates a much higher power than is required for the conveyance of the ore. The surplus power is utilized in compressing air. The grade from the transfer station to the mill is just sufficient to provide for the conveyance of the ore. The smelter consists of three 250-ton water jacket furnaces, the fumes from which are conducted by individual goosenecks to a hopper bottom dust chamber 280 feet long, where the dust and fumes are collected. At the south end of the dust chamber the stack, which is constructed of boiler-plate steel 150 feet high and 12 feet in diameter, stands. This stack is deeply seated in a concrete base so that it needs no guys to insure its stability. Under the dust chamber there is an electric track which leads the cars to the briquetting plant. The building containing the furnaces, which is the smelter proper, is 130 by 70 feet. There are two levels to the building — the lower for the tapping and the higher for the charging floor. From the former tracks lead away to the slag dump. Behind the smelter building is the storehouse, in which the fluxing ores, limerock, coke and custom ores are to be stored. It is 214 feet in length, and the railroad enters it at an elevation of about 20 feet greater than the charging floor. These tracks lead over to the bins and the ore is dumped in by gravity. Twenty-seven scales provide for the individual weighing of the cars. The sampler is situated at the north of the custom ore bins. The ore capacity of the bins provides for 1000 tons of the company's ore; 1200 tons of limerock and 2500 tons of custom ores. The blower house is 80x50 feet, in which are three blowers driven by three motors of 200 H. P. each. Each of the blowers will deliver 18,000 cubic feet of cold blast a minute. The capacity of the tram for delivering ore is estimated at 1600 tons a day of twenty-four hours. Each bucket has a capacity of 1100 pounds and they are placed at intervals of 150 feet on the rope.

Siskiyou County.

The new dredger, near Yreka, on Yreka creek will begin to dig September 4. This is the second dredger built on this ground. The first was on the scoop pattern, and was a failure. The present one is a modern, up-to-date bucket dredger.

Tuolumne County.

Work is to be resumed with power drills at the south extension of the Black Oak mine, near Soulsbyville.——It is reported that work is to be resumed at the Donella mine, near Arrastraville, by J. E. Conde.——At the Dutch mine at Quartz a sump is being put down from the 1720 level and a station is to be cut preparatory to drifting to the pay shoot. In the mine and mill sixty men are employed. A. Trittenbach is superintendent.——It is reported that a rich strike has been made on the 700 level of the Lightner mine, Angels Camp.——At the New Calico, east of Stent, since work was begun on April 6, the main vertical shaft has been sunk 225 feet and 1000 feet of drifting and crosscutting done. Sinking has been temporarily suspended and a crosscut started east from the bottom. An 8-drill air compressor has been ordered. J. A. Thompson is general manager.

COLORADO.

Clear Creek County.

The Central tunnel of the Big Five Tunnel, Ore Reduction & Transportation Co., near Idaho Springs, is in 4420 feet and is to be continued 5000 feet farther. It is to cut the veins of the Quartz Hill district. The ore transportation charges for mill ore, according to the Mining World, are 4 cents per cubic foot for 5000 feet or less of haulage and ½ cent per cubic foot additional for each additional 1000 feet or fraction thereof to 15,000 feet. For tramming smelting ore $1 per ton additional is added to the other rates, and waste is hauled for one-half the above rates. Air is furnished for driving drills at the following rates: Leyner drill, No. 5, each drill $4 per shift. Plunger drill with 2½-inch cylinder or less, each drill $4 per shift, with an increase of 25 cents for each ½ inch increase in diameter of drill cylinder; eight hours to constitute a shift and any less number of hours to be charged as full shift; if air be furnished for longer than eight hours at one time extra time will be charged pro rata for each hour or fraction thereof of thirty minutes or over. Sharpening hand drills, 3 cents each; sharpening plunger drill bits, 6 cents each; sharpening Leyner drill bits, 7 cents each; sharpening picks, per point, 3 cents each; sharpening gads, moils, chisels and similar tools, 3 cents each; making hand drill bits, 6 cents each; welding plunger drill bits, 25 cents each; welding Leyner drill bits, 35 cents each; laying picks, per point, 50 cents each; making plunger drill bits, with one weld, 65 cents each; making Leyner drill bits, two welds, not including making shank, 75 cents each; general smithing, smith only, 75 cents per hour; general smithing, smith and helper, $1.25 per hour. No charge less than 25 cents. The Newhouse tunnel is in nearly 3 miles and is transporting ore from the Gem, Sun and Moon and the Saratoga. This tunnel charges for the first mile, smelting ore, $1.25; mill ore, 65 cents; waste, 25 cents a ton, which charges increase proportionately up to $2 a ton for smelting ore with added distance. This and the other tunnels furnish free drainage for properties along the line of the tunnel, and are purely transportation enterprises; it is optional whether the companies owning the veins cut operate through the tunnel or not. The advantage of tunnel transportation is so great, notwithstanding the arbitrarily high charges, that practically all the ore in the veins cut by the tunnel, within a lateral distance of half a mile along the tunnel course, will be taken out through the tunnel. In the case of the Newhouse tunnel, the tunnel company has no financial interest in the mines along its course, and it furnished the funds for driving the tunnel, except that in some cases arrangements were made with mining companies to advance funds for the work, to be credited on future transportation charges. The tunnel cost about $500,000. The tunnel is equipped with a double track and an electric trolley system of haulage. The portal is immediately upon the railroad track and the ore cars are dumped automatically into bins for loading by gravity into cars. The Newhouse tunnel is 9x12 feet and the Central 6x8 feet, single track. These tunnels have cost $15 to $25 per foot to drive, no timbering being used except at the portals.

The R. E. Lee tunnel of the Southern M., M. & Dev. Co. on McClellan mountain, near Silver Plume, is in 460 feet. Above the R. E. Lee a crosscut is being driven to the King of the West lode. F. A. Babcock is superintendent.——The Dives-Pelican mill, near Silver Plume, is now running continuously, as a larger dynamo has been put in for driving the Huntington mills. A large duplex pump has been put in to supply the mill with water from the creek.——It is reported that B. J. O'Connell intends driving a lower tunnel on his property on Republican mountain, near Silver Plume.——Superintendent Cæsar Garrett of the Colorado Central property, on which F. A. Maxwell recently secured a lease and bond, reports that the task of cleaning out the old workings and putting them in shape for operation is completed, and that a large ore production will now be commenced.——D. W. Stewart of Idaho Springs has secured a bond and lease on the Blue Bird claims from Wm. Hunt of Georgetown and Nels Frohm of Denver. He proposes to continue work on the crosscut, which is in more than 800 feet.——A strike is reported from the Dictator property on Columbia mountain, near Georgetown, being operated by George August under lease.

Gilpin County.

The Gold Dirt mill at Perigo, 3 miles above Rollinsville, has been started up. E. C. Englehardt has charge of the cyanide plant. The crushed ore is carried from the Huntington re-grinder (where it is ground to 100 mesh) by an elevator to hydraulic sizers, and the sands from the sizers run by gravity to revolving barrels, where they are cyanided, the process being completed in four hours. The slimes from the sizers are settled in six 10x20 slime tanks, the first two receiving them, the overflow passing into the other four. In due course the settlings with the solution are pumped through the entire series of tanks. The mill is equipped with compressed air, bullion furnaces and assay office. The main inclined shaft of the Gold Dirt mine is down 700 feet, but Manager Anderson is sinking a new vertical shaft near the mill. The mill is an experiment to treat by cyanide pyrite ores.

The Druid G. M. Co. is operating in Willis gulch of the Russell district under the superintendency of C. W. Anderson. Operations in the main shaft are being car-

ried on in the 150 and 200-foot levels, drifting being carried on in the 200-foot level, where ore is showing up on both sides of the shaft, while stoping is in force in the east and west 150-foot levels. Both milling and smelting ores are being taken out, the milling ores being sent to the Polar Star mill, while the smelting ores go direct to the smelters in Denver.

At the Pride mine, on Mammoth hill near Central City, the main shaft is down 180 feet. Hoisting is being done with a whim, but M. E. McLain intends putting in hoisting machinery soon.

The Chemung-Belmont mine, near Lake gulch, has been started up under the foremanship of Wm. Willis of Central City. The property is being operated by the Central Bonding & Leasing Co. with Chris Hesselbine of Denver as manager. Work was resumed in the main shaft with a contract for 100 feet of sinking, the shaft being down 600 feet. Drifting will be commenced on both sides of the shaft at the 600-foot point.——It is reported that machinery and topbuildings will be put on the No. 2 shaft on the Russell property of the Russell M. Co. The company owns the Russell and West Pewabic in the Russell district. Frank Paxton is superintendent.——It is reported that the Hillhouse mine in Russell district, owned by Potter & Co. of Central City, is to be started.

It is reported that work is to be resumed on the Gunnell properties in Eureka district, near Central City. New machinery is to be put in. F. C. Young of Denver is manager.

Gunnison County.

The aerial tramway of the West Gold Hill M. Co., which runs from the Carbonate King claim to the mill, near Tin Cup, is in working order. A tram from the Iron Hat to the Carbonate King, where the ore is transferred to the mill tramway, is also in place. The track has been laid in the Carbonate King incline and ore is being taken out. L. Cavnah is in charge.——The Keyes Placer M. Co. has men and teams working on their ground, 7 miles northwest of Tin Cup, making preparations for hydraulic mining next spring, as the ditches cannot be gotten in shape until too late for work this fall. The old ditch in Dry gulch is being repaired and water from Willow, Cow, Pass and Texas creeks will be used.——A new strike has been made by Charles Stiles on the McKinley property on Anna mountain in the Tin Cup district.

Hinsdale County.

Machine drills are to be put in the Wyoming mine, near Lake City, by Superintendent W. G. Pitts.

Lake County.

The Fortune mine, near Leadville, owned by James McNeece, has been leased to Geo. Becker, T. S. O'Brien et al. Development is being continued to the upper workings. The drawing of the pumps from the lower levels of the Resurrection has not flooded the lower levels of the Fortune, and work from the bottom of the shaft will be carried on next month after the lessees have prospected the ground and located the ore shoots. The Resurrection is working the upper levels and shipping a fair grade of iron.

Park County.

The Almaden M. Co., operating at Alma, has acquired the Colorado claims near the Golconda mine, on Fall river, and is preparing to put in machinery. W. T. Dumbleton is in charge.

San Juan County.

On King Solomon mountain, near Silverton, the Arpad M. Co. is running a new tunnel with three shifts. The Arpad Co. is composed of Denver people, with Theodore Grabowsky as general manager and mine superintendent.——A 2700-foot flume is being built by Charles Dale from Stony creek to Old Hundred mill in Cunningham gulch. A tank is being put up for the Old Hundred Co. for a reservoir at the mill. Its diameter will be 15 feet and its height 12 feet.——An air compressor and drills are to be put in at the new 1000-foot tunnel to be run by the Mayflower Co. from Arrastra gulch, near Silverton.

Summit County.

The Beaver Creek G. M. Co., which is operating the Old Lucky and adjoining lodes on Mineral hill, near Breckenridge, has had the concentration mill on the property running on ore from the mine. The management will add a number of concentrating tables to the plant later on. At present the concentration of the second-class ore is being done with Hartz jigs. By adding concentrating tables the capacity of the plant will be increased. G. E. Moon of Breckenridge is superintendent.

Niles & Walker have nearly finished building a 5-stamp mill and concentration plant near the mouth of the lower tunnel of the Laurium in Illinois gulch, near Breckenridge.——The Quandary mill, near Breckenridge, is to be overhauled and its capacity increased to 100 tons a day. W. H. Harrison of Grand Island, Neb., has been at the mine.

Teller County.

C. G. Jackson & Co. have a lease on the Fountain Valley claim of the Banner G. M. Co., between Beacon and Rosebud hill, Cripple Creek. Work is to be started as soon as a compressor has been put on the Mary Nevin. The main shaft is to be sunk 100 feet deeper, giving a depth of 438 feet.——Tube mills are to be used at the Little Giant mill in Pony gulch, 3 miles southeast of Cripple Creek, to crush the ore for cyanide treatment. ——The Last Dollar G. M. Co. of Cripple Creek has resumed hoisting after a short shut-down to repair the hoist. It now can handle 50% more rock than before. ——Manager E. M. De La Vergne of the Elkton Con. expects to finish repairing and retimbering the Elkton shaft by Sept. 1.——Gold-bearing ore is reported to have been struck by Lessees Duncan and Kain in the east end of the Teutonic property of Ironclad hill.

IDAHO.

According to E. W. Parker's statistics in the U. S. Geological Survey's report on "Coal Production in 1904," Idaho produced 3330 short tons, with a spot value of $12,230. The only coal areas of Idaho from which any production has been obtained are found in the Horseshoe bend and the Jerusalem districts, occupying the lower portion of a ridge between the Boise and Payette rivers, in front of the Boise mountains. In the Horseshoe Bend district there is one seam of high-grade lignite of about 3 feet in thickness. The Jerusalem district, which contains four different seams averaging from 3 to 8 feet in thickness, also contains lignite of about the same character as that of the Horseshoe Bend district. There are two other occurrences of coal in the State—one near Salmon City, the other at the northern edge of the State, where the Sublette field of Wyoming extends across the line. No mining is carried on in either of these districts at the present time. The production from the Horseshoe Bend and Jerusalem districts has been very irregular, never reaching any commercial importance.

Custer County.

At the Golden Sunbeam, 7 miles from Custer, Superintendent Gable has ten men at work. The mill is running. ——Considerable excitement has been caused by the recent strike at Parker mountain, between Custer and Challis.——It is reported that John Wallace of Boise will put a dredger on his placer mine near Bonanza.

Nez Perces County.

A. C. Weary and G. S. Ellinger of Chicago have returned from a visit to the Gold Crown mine, on the upper Snake river, near Cave gulch. They will arrange for a 100-ton cyanide plant. The property is managed by J. M. Edwards of Lewiston.——G. A. Garvin and I. S. Hammond of Portland have completed arrangements for a cyanide plant at Lewiston to handle black sand from the Snake and Clearwater rivers. The plant will have a capacity of sixty tons per day at the beginning. The black sand is separated from the gravel on concentrating tables.——The Ry-Bar M. Co. is operating a concentrating plant 3 miles south of Lewiston, on Snake river, and is securing 800 pounds of concentrates daily. The process is new, having been perfected by the local assaying firm of Jellum & Jones.

Owyhee County.

The War Eagle Consolidated Co., of Silver City, are cleaning out the Oro Fino tunnel, which drains the mines belonging to that company to the depth of 400 feet, with the intention of pumping out the Chariot shaft through that tunnel. The men who have been making the upraise from Sinker tunnel have been laid off and work from that point suspended until the shaft has been pumped out and surveys made to ascertain where they are at. The manager had contemplated tapping the bottom of the Chariot shaft with a diamond drill, starting the hole from the Sinker tunnel upraise, now up from the tunnel 600 feet, with 300 feet more of a raise to make to reach the bottom of the shaft. But the uncertainty of driving the hole right, and the danger of tapping a body of water with 1000 feet pressure, even with a drill hole, were too serious engineering problems to be solved by that means.——The De Lamar mill at Silver City is being overhauled.——A. Buckbee, manager of the Pioneer M. Co. of Silver City, has contracted with the Trade Dollar Co. for electric power; ordered a motor, and is having a survey made to the Cumberland mill from the power line now running up War Eagle to the Poorman, and having a transformer put up at the mill, for the purpose of having the mill run by electricity.——The Addie M. Co. is pushing the reconstruction work on its mill, but will require two weeks to get it ready to start, new pans and settlers being put in.

Washington County.

Manager S. Peacock of the Ladd Metals Co. of Landore states that his company is putting in a reverberatory furnace of fifty-five tons daily capacity.

MICHIGAN.

Houghton County.

The Allouez, which has been operating one skip, has placed a second one in commission and resumed sinking for the fifth level. At the Centennial mill a second head is being overhauled to give the Allouez the exclusive use of one head instead of having Centennial run three days and Allouez three days alternately on the same head. This second head will be available for Allouez in a week. About two-thirds of the rock going to the mill comes from underground, while one-third comes from the stock pile which accumulated from the openings before the milling began. The buildings completed at No. 1 are the steel shaft rock house, the steel and stone engine house, the stone boiler house, with four boilers, the compressor house, the machine ship, which at present contains the blacksmith shop, and the change house. Work is progressing favorably at No. 2 location, in getting into shape for sinking the permanent shaft. The third drain shaft is going down very well, having reached a depth of 50 feet, and the flow of water is decreasing there, while in the first and second drain shafts it has been reduced to a very marked degree.

At the Erie-Ontario property the steam power hoisting engine has begun service. As this replaces the derrick and horse power which have been in use, the work will be prosecuted with greater facility. An air compressor has been put in at the Erie-Ontario.

MISSOURI.

Jasper County.

The Cataract M. Co. intend to put up a new 150-ton mill on the Gover land, at Chitwood. R. S. Neal is manager.

Stone County.

The Oronogo mill, on the Riddle tract, southwest of Galena, has been burned. It was operated by Robert Murdock and James Keyes. The loss is estimated at $5000; insurance, $1000.——Schellack & Co. have started a shaft on the Weyman tract, northwest of Galena.

MONTANA.

According to the report of the U. S. Geological Survey on "Coal Production for 1904," Montana's total coal production in 1904 was 1,358,919 short tons, valued at $2,194,548. Although most of the coal of Montana is of Cretaceous age, coal-bearing formations are found in all rocks, from the Jurassic to the Tertiary. The coal found in the Jurassic, however, is too thin to be profitably worked. The coals of Montana vary in character, from lignite to bituminous, some of the latter being fair coking coals. The total area of Montana underlain by coal is estimated at 32,000 square miles. The producing areas are in somewhat widely separated fields, among which may be mentioned the Bull Mountain field, northeast of Billings, where a considerable amount of prospecting and development work has been done. The coal of this field is lignitic in character. In the Clarks Fork field, in the southwestern portion of Yellowstone and northeastern part of Sweetgrass counties, and extending southwestward through Carbon county, the coal is lignitic and not at present worked to any large extent. The Rocky Fork field, in Carbon county, contains five different beds of coal, varying in thickness from 4 feet to 7 feet 9 inches. All of this coal is between lignite and bituminous and said to make an excellent steam and domestic coal. The Yellowstone field and the Trail Creek field are in Park and Gallatin counties and cover the operations in and around Bozeman and Livingston. The Cinnabar field is a small area lying just north of the Yellowstone National Park, and west of this are the West Gallatin and Ruby Valley fields, which have not yet been developed to any great extent. Other areas are the Toston, Smith River and Belt, or Great Falls fields, the last mentioned being the most important. Some of the largest mines in the State are those at Cottonwood, in Cascade county. Judging from the activity in the coal mining industry of Montana, there has been little or no change in the industrial conditions of the State during the last ten years. Coal production has remained practically stationary during that time, ranging from a minimum of 1,358,919 short tons in 1904 to 1,661,775 in 1900, and averaging 1,513,818 short tons for the entire period. The greater part of the coal production in Montana is used by railroad locomotives, and as there has been no railroad building to speak of in the State for the last ten years, the stationary condition of the coal mining industry may be accounted for. The production in 1904 was the smallest tonnage recorded since 1894. Compared with 1903, when the output was 1,488,810 short tons, the production in 1904 exhibits a decrease of 129,891 short tons, or 8.7%. The value of the product decreased from $2,440,846 in 1903 to $2,194,548 in 1904—a loss of $246,298, or a little over 10%. During 1904 the coal mines of Montana gave employment to 2505 men, that averaged 243 working days each, against 2155 men for 254 days in 1903. The average production per man employed for the year in 1904 was 542.5 tons, against 691 in 1903 and 805 in 1902. The average daily tonnage per man was 2.23 in 1904, 2.72 in 1903 and 2.98 in 1902. The majority of the mine workers in Montana worked nine hours a day, all of the larger mines but two reporting a 9-hour day. There were nineteen mines, employing altogether 646 men, that reported eight hours; eight mines, employing 1653 men, reported nine hours, and four mines, employing twelve men, worked ten hours.

Deer Lodge County.

After being closed down a month to permit of the retimbering of the shaft, operations have been resumed at the Never Sweat mine at Butte. During the time the mine was out of commission no ore was raised, but a number of miners were engaged in opening up new ground and doing other dead work.——At the Mountain View of the Boston & Montana, the new boilers for the new hoisting engine will be finished soon. The job is not interfering with the mining of ore in the property.

Fergus County.

The Hedges G. M. Co., owning seven claims at Kendall, is preparing to do diamond drill work for the purpose of determining the extent of the ore bodies in its Mary claim, on which a shaft was sunk some time ago. This is now on a ledge of ore at a depth of 75 feet. Its tract comprises 140 acres. The officers are M. M. Hedges president, C. M. Goodell vice-president and J. W. Hedges secretary-treasurer.

G. S. Wells has sold to A. M. Plumb the Edna property at Kendall, and the owner will develop this prospect at once.

Madison County.

E. W. Merritt is running 100 tons of ore from the Highup mine through the Shafter mill, near Virginia City. The mine is at the head of Hungry hollow and is developed by a tunnel, the face of which is in 250 feet.

Silver Bow County.

(Special Correspondence).—A new and large ore body has been opened in the Corra mine, one of the United Copper properties, and the mine is now shipping 600 tons of ore per day.——The Lexington mine, an old silver producer, is turning into a copper property. F. A. Heinze is developing the mine and is shipping about fifty tons of copper ore daily. The Lexington will go into the new La France C. Co.— The August output of copper from the whole Butte district will exceed 31,000,000 pounds, and of that amount the Washoe smelter, at Anaconda, will contribute 15,250,000 pounds, the highest mark in the history of the smelter. The Washoe treats the ores from the mines of the Anaconda, Washoe, Parrot, Trenton, Speculator and Butte & Boston Cos.—— With the exception of several mines that are closed by injunction in the Heinze-Amalgamated litigation every property in the Butte district is working, many mines to their utmost capacity. The stimulus is the high price of copper and the fact that there is comparatively little stored.——The North Butte M. Co. is shipping about 800 tons of ore a day.

Butte, Aug. 29.

NEVADA.

Esmeralda County.

(Special Correspondence).—In the Goldfield district the following mines have reached water level and the sulphide zone, and are producing sulphide and undecomposed ore: The Florence, Combination, Red Top, January, Quartzite, Jumbo and Silver Pick. Several leasing companies on the above mentioned properties are now sinking to get to the sulphide zone.

Goldfield, Aug. 28.

Lincoln County.

(Special Correspondence).—The Shenandoah lead-silver patented mine has been bought by Judge Barton, of Pioche.——Development work on the Chiquita gold mine improves the size of the ore body, and arrangements are under way to mill the ore in the Keystone mill at Sandy.——The Potosi lead-silver mine has 35 men at work. Ore is shipped by the San Pedro & Salt Lake railroad to the smelter in Salt Lake valley, Utah.——D. W. Johnson is developing a lead-silver mine.

Sandy, Aug. 29.

An automobile line has been established between Searchlight and Leastalk, on the Salt Lake route, and Manvel, on the Santa Fe.——F. D. Howells intends to continue sinking the Sazerac shaft at Searchlight till the lower ore bodies are reached, estimated at a depth of 800 feet.——Gordon Surr has resumed cyaniding the tailings from the Cyrus Noble at Searchlight.——The Searchlight Bonanza M. Co. has been formed, with H. A. Perkins as manager, to work the Black Bear, Nevada, Lion and Iowa claims. A 200-foot shaft is to be sunk.

Lyon County.

The Nevada Smelting Co., which has recently purchased the plant of the Boston-Nevada Smelting Co., is trying to make contracts with the copper mine operators near Yerington for sufficient ores to run for ten years a smelter they plan to establish. The company offers to reduce the ores at the rate of $10 a ton and buy the copper at the regular market price.

Nye County.

A 15 H. P. gasoline hoist is being put in at the Steinway mine, near Bullfrog. Sinking is to be resumed.——Superintendent McCauley is putting in a new gasoline hoist at the Great Eastern mine, near Bullfrog, and will resume sinking from the 110-foot level.——After reaching a depth of 330 feet work has been stopped at the Amargosa, at the south end of Ladd mountain, Bullfrog district, until a new hoist can be put in.

Storey County.

The steel headframe at the Union shaft at Virginia City has been completed and the rope changed from the temporary wood gallows frame. This is the first steel headframe to be used on the Comstock, and was put in to replace the frame destroyed by fire.

White Pine County.

It is reported that the smelter of the Con. M. Co. at Ely is nearly completed. This is to have a capacity of 250 tons, and Superintendent J. L. Giroux hopes to treat 100 tons of ore with eight tons of coke.

NEW MEXICO.

Dona Ana County.

The Modoc M. Co. has resumed work at Organ and will put in a new dry process to treat its low-grade ore. Shipments of lead ore are being made to the smelter at Deming. —— The Stephenson-Bennett Con. M. Co. has put in a new air compressor and is pushing work on its double-compartment shaft, which will be sunk to a depth of 450 feet to cut the old Bennett vein on its dip.

Grant County.

The St. Louis Copper Co. is working the Garnet group at Jarilla under lease and bond. The shaft is down 400 feet and a number of shipments of a good grade of ore have been made. As soon as electric power can be had an electric hoist and electric drills are to be put in. —— The Lincoln Copper Co. is developing claims at Jarilla and will put in electric machinery as soon as the contemplated electric power plant of the Southwest S. & R. Co. has been built. A double-compartment shaft and a crosscut are planned.

Taos County.

The Mammoth mill at Pinos Altos has been running steadily on ore from the Mina Grande, which Walter Brandis, the superintendent of the mill, has under lease. The mill has been treating twelve tons a day, but the capacity is to be increased shortly to twenty-five tons, and two shifts will be put on, both at the mines and the mill. Brandis also has a lease on the Mogul. A tunnel connection will also be made with the Mina Grande, so that ore from the latter may be taken out of the Mogul shaft.

OREGON.

Baker County.

The ore body cut on the 400 shaft level of the Baisley-Elkhorn mine, near Baker City, is being drifted and is said to be equal to that mined on the upper levels of the property. The ore was found on a diorite-granite contact at a depth of about 700 feet, as the collar of the shaft is in a long crosscut having a depth of 300 feet.

Douglas County.

The mill of the Oregon Securities Co., at Bohemia, has been shut down since August 1 on account of lack of water. Prior to the mill closing the stamps were treating between fifty and sixty tons a day. The management expects to start the mill on October 1, and keep it in continuous operation.

Tillamook County.

Drilling for oil in the Nehalem district has commenced under the direction of the Portland Development Co. A standard rig drill has been secured and is said by the management to have commenced boring. It will drill to a depth of 2500 feet, if necessary, to prove the formation.

SOUTH DAKOTA.

Lawrence County.

The Dizzy M. Co., in False Bottom gulch, 3 miles from Maitland, has resumed work with two shifts. The work was stopped by water recently, but a pump with a capacity of 200 gallons per minute has been put in. H. H. France is superintendent of the company.

Pennington County.

The Mainstay Co., at Keystone, is having an artesian well drilled to a depth of 400 feet below the bottom of the shaft, making a hole 700 feet deep. Machinery is being received.

UTAH.

Beaver County.

A gasoline hoisting plant has been put on the Moscow mine, near Milford. William Ferguson is superintendent.——The Lenora M. Co. is shipping high-grade silver-lead ore from Milford. The Lenora group is in Star district. M. L. Burns and son are the owners.——J. C. Brownfield, manager of the Wasatch King M. Co., in Beaver Lake district, has driven the tunnel in over 400 feet.

Juab County.

The ore shipments from Tintic district were 148 carloads for the week ending August 24: Centennial-Eureka, 62; Eureka Hill (lease), 6; Bullion-Beck, 6; Gemini, 12; Victoria, 6; Grand Central, 6; Mammoth, 13; Carica, 5; Ajax, 4; Swansea, 7; South Swansea, 1; Eagle & Blue Bell, 14; Yankee Con., 2; Uncle Sam, 4. Two carloads of concentrates were shipped from the Uncle Sam mill.——Work is progressing satisfactorily at the Raymond-Illinois property, north of Eureka. Superintendent J. C. Sullivan is running a drift from the 1500-foot level, so as to tap the ore extension of Tintic in the north.——A body of silver-lead ore has been cut by W. R. McComb in the old workings of the Gomery claims, in East Tintic.

Salt Lake County.

At the Fortuna mine at Bingham machine drills are at work in the crosscuts. A gasoline hoist is being put in on the main working level, where an old shaft was cut. This shaft is to be sunk deeper, to give a depth of 1500 feet on the vein.

The management of the Congor mine at Bingham is having difficulty in unwatering the lower workings and the examination by representatives of the holders of the existing bond is being delayed. G. G. Hall is manager. ——H. M. Crowther, manager of the Continental Alta mine at Alta, states that the first shipment of wulfenite concentrate from that property is ready.

The Phœnix M. Co. of Bingham has put in an electric air compressor. The building is 18x50 feet.——The Ohio Copper Co. will sink to the 500-foot level.

Summit County.

To get around the last cave in the Ontario drain tunnel at Park City it has been decided to employ the same tactics that were used to draw off the water without endangering the lives of the men employed when the first bad cave was struck, and which, at the time, was thought to be the one that was holding back practically all of the water and allowing the mine to fill up. First the ground was tested by driving pipe into it. That was followed by Superintendent M. Connolly drifting into the mass for 50 feet. From that point he has put men and machine drills at work to parallel the main tunnel with a new one. Where this work is being done the ground has been considered rather treacherous for 400 feet ever since the tunnel was constructed. That being so, Superintendent Connolly will probably push the side drift for the distance named. Strong concrete and steel bulkheads will then be put in, as in the first instance, and a large number of holes will be drilled through to the main tunnel from the pipes set in the bulkhead and equipped with valves to control the water as each puncture is made. This will probably take four months more.

WASHINGTON.

Okanogan County.

Henry Bahrs, manager of the Copper World Extension M. Co., at Loomis, is sinking a shaft on the Copper World Extension mine. This shaft is down 150 feet and will be sunk to a depth of 300 feet before any more crosscutting will be done.——The Douglas mountain tunnel, on Palmer mountain, which is to be driven 3000 feet in all, is now in 308 feet.

Stevens County.

The traction outfit of the Copper King mine is delivering 60 tons of ore per day to the railroad for shipment to the Northport smelter.——The Nellie S. mine has four men at work sinking on the main shaft near Chewelah. President H. H. Baker has charge of the work.

FOREIGN.

AFRICA.

Transvaal.

The Main Reef series has been cut at a depth of 3862 feet in the shaft of the Angelo Deep, east of Germiston. The shaft of the Cinderella Deep at Boksburg is also close upon the Main Reef. There are now between 40,000 and 45,000 Chinese at work in the Rand mines, and, beyond a little friction with the white miners, no serious trouble has been experienced.

AUSTRALIA.

New South Wales.

The New South Wales gold yield for July amounted to 39,862 ounces, valued at £128,092, as compared with 27,169 ounces, valued at £102,486, in the corresponding month of last year. The total yield for the seven months ending July 31 was 171,140 ounces, valued at £603,280, as against 196,216 ounces, valued at £704,312, in the first seven months of 1904.

Victoria.

Regarding dredger mining and hydraulic sluicing in Victoria during 1904, D. B. Sellars in his annual report to the Secretary for Mines and Water Supply, says that twenty-two bucket dredgers working for an aggregate period of 839 weeks raised 4,653,026 cubic yards of material for a yield of 18,962 ounces of gold, or 1.9 grains per cubic yard. The area treated was 202 acres, the quantity of gold saved per acre being 93.7 ounces. The dredger which treated the most material got 1479 ounces for fifty-one weeks' work, from 19½ acres of ground, which averaged 1.5 grains of gold per cubic yard of material dealt with. The average weekly yield of gold per plant was 22.6 ounces. The number of men employed was 325. Thirty-one pump hydraulic sluices for an aggregate working time of 912½ weeks dealt with 5,302,014 cubic yards of overburden and washdirt for a return of 29,294 ounces of gold, or 2.65 grains per cubic yard; 23 tons 15 cwt. of tin were also won. The area worked was 136½ acres, the quantity of gold saved per acre being 214.4 ounces. The plant with the highest yield got 3078½ ounces from 14½ acres of ground, containing 660,660 cubic yards of material, or an average of 2.2 grains per cubic yard. The average weekly yield per plant was 32.1 ounces, and the number of men employed was 1015. One other plant working gave 51 ounces, but further particulars are not available. Six hydraulic jet elevators working for an aggregate of 109 weeks put through 237,360 cubic yards of alluvium for a return of 1463 ounces, or 2.95 grains of gold per cubic yard of material treated; 19 cwt. 3 qrs. 2 lbs. of tin were also won. The area dealt with was 7⅞ acres, the quantity of gold won per acre being 185.8 ounces. These six plants provided work for 69 men. An additional yield of 256 ounces was obtained from five other plants, but other information is not available. In all, fifty-nine dredger mining plants, comprising twenty-two bucket dredgers, thirty-one pump hydraulic sluices and six jet elevators, treated 10,192,400 cubic yards of material for a yield of 49,718 ounces of gold, or an average of 2.34 grains per cubic yard of solid matter dealt with. The area worked was 346.7 acres, which averaged a return of 143.4 ounces of gold per acre, and employment was given to 1409 men. From returns supplied in connection with hydraulic sluicing by gravitation, it appears that there were ten plants operating, of which seven were working under leasing conditions and three under mining by-laws of the district. The aggregate number of weeks worked was 181, the quantity of overburden and washdirt dealt with being 464,842 cubic yards for a return of 3014 ounces, or at the rate of 3.1 grains of gold per cubic yard of material treated. The area worked was about 9½ acres, the quantity of gold saved per acre being 313.9 ounces. The highest yield was 1646 ounces from four acres. These plants gave employment to 83 men. Four other plants gave an aggregate return of 80⅛ ounces of gold and 35 tons 9 cwt. of tin; further particulars not available. Other plants working sent in no returns. An additional yield of 2136 ounces was obtained by small sluicing parties working under miners' right. The total quantity of material treated during the year under the heading of dredger mining and hydraulic sluicing by gravitation was 10,657,242 cubic yards, as against 7,963,927 cubic yards for 1903. The amount of gold obtained shows an increase of 13,211 ounces, being 55,257 ounces, as against 42,046 ounces. The yield of gold per cubic yard of material treated was 2.375 grains, as against 2.39 grains for the previous year. The number of men employed was 1505, and the total area treated 356⅛ acres. The quantity of tin obtained during the year was 60 tons 3 cwt. 3 qrs. 26 lbs. It is satisfactory to note that the elevator as an aid to mining has disappeared from the bucket dredgers. Originally there were seven plants in use fitted with this appliance; at present there are none. It has been discarded in favor of the box sluice. Box sluices, furnished with a silt distributor by means of which the finer materials are spread out evenly and regularly over the top of the coarse material, are now doing good work in the Bright and Omeo districts. Experience shows the necessity of having, when dealing with very light wash or stiff clayey material, greater power for the nozzle than for the elevating pump in hydraulic sluicing, otherwise much financial loss occurs through pumping large quantities of simply useless water. It is generally supposed that ground having once been treated by a dredger becomes useless thereafter for mining purposes. In the case of stiff, clayey ground, however, this rule does not always hold good. Two cases have occurred during the past year where bucket dredgers have worked through, at a profit, previously dredged ground, and in one other case similarly treated ground yielded sufficient gold to pay working expenses.

CANADA.

BRITISH COLUMBIA.

Boundary District.

Chicago men have completed an examination of the Chicago-British Columbia M. Co.'s properties in Skylark camp, 2½ miles from Phœnix. In the party were J. Gerts, vice-president of the company; N. Kuhnen, treasurer; T. T. Mueller and L. Warneke. They were met by Manager H. H. Shallenberger. The group consists of the Lake, Iola, Yellowstone fraction, Crescent fraction and Don Pedro.

Ore shipments from the mines of Boundary for the week ending Aug. 26 were: Granby mines to Granby smelter, 9137 tons; Mother Lode to British Columbia Copper Co.'s smelter, 3328 tons; Emma to Nelson smelter, 390 tons; Skylark to Granby smelter, 20 tons. Total for week, 12,875 tons; total for year to date, 571,-007 tons. Boundary smelters this week treated ore as follows: Granby smelter, 11,102 tons; British Columbia Copper Co.'s smelter, 1956 tons. Total treatment for week, 15,058 tons; total treatment for year to date, 585,-534 tons.

Slocan District.

The London Hill D. & M. Co. has let a lease and given a bond on its two claims on London hill at Bear lake to A. E. Eckert of Sandon.

Yale District.

Regarding the Similkameen division the British Columbia Mining Record reports that development work on the Sunset, at Copper mountain, by the British Columbia Copper Co., is proceeding satisfactorily, and fine ore is being met with on two drifts on the lead. The drift into the porphyry has been run 118 feet without reaching the contact. A few tons of ore were lately shipped for the purpose of having tests in concentration made. The ore is high in silica and low in lime and iron, so it presents a more difficult smelting problem than the copper ores of the Boundary. Some effective method of concentration would greatly simplify the treatment of this ore. The management are considering the feasibility of driving a tunnel from the Princess May claim with

the object of striking the Sunset lead at greater depth. This tunnel would have to be nearly a mile in length and would pass through a number of claims having good surface showings. Between 20 and 25 men are working on the Sunset.——Pouwells & Bonnevier have completed a 50-foot shaft on the Red Star at Roche river. ——Within two miles of Princeton, on One Mile creek, W. C. McDougall is employing several men on the United Empire group. During the past six months, on this group, a tunnel was run 150 feet, and a shaft sunk on a vein carrying copper and gold. Average assays are said to show values of $24.65 to the ton. A wagon road is being constructed to connect the property with the main trunk road up and down the valley.——Between Princeton and Granite Creek, on the Tulameen river, Oswald Coulthard is working on the Roany claim. ——An important resource that promises to be of commercial value is found in connection with the coal in this district, in the shape of an excellent fire clay that approaches closely in quality the best Scotch and English clays. A seam between 2 and 3 feet in thickness has been exposed in the tunnel the Vermilion Forks Mining & Development Co. has driven on its large coal cropping near the Similkameen bridge.

CHINA.

The Mining Journal reports that to the north of Tonkin, near the Chinese frontier, in the district of Cao-Bang, there are extensive tin deposits. These deposits lie in a high valley on the side of the Pia-Ouac mountain, in the district of N'Guyen-Binn, circle of Cao-Bang. They were discovered in 1899 by G. Gaillard and Duverger. Tin has long been mined by the Chinese in the alluvial deposits formed by erosion. The grant of Tinh-Tuc has already given excellent results, in spite of the primitive plant available. A granulite formation along the crests of the mountains contains the mineralized stock work of cassiterite, accompanied by wolfram and quartz. There are some valleys formed of privileged placers where the cassiterite is workable on strata of fine material containing white mica, tourmaiine, obsidian and quartz. Cassiterite is found scattered about with a little gold and wolfram in the deposits of the upper valley. The proportion of the cassiterite increases with the depth of the alluvium. The barren superficial earth is so much thicker and more clayey as it occupies the lowest parts of the valley. The average percentage of tin is 50%, though some samples have given 65%. The proportion of ore to the cubic meter of earth treated is, after washing, an average of 5 kilograms. Washing experiments made at various parts of the deposit gave 2.800 to 9.500 kilograms of cassiterite per ton of earth treated. A certain number of small local workings treat the ore on the spot, after washing, in Chinese furnaces, with very primitive blowing apparatus, employing wood as fuel. Nevertheless the yield attains 80% of the analyses of the ore utilized. In rich parts of the veins one, and exceptionally two, kilograms of metal are obtained per Chinese coolie per day. The claim of Duverger freres, which is the most important, was established on the Tinh-Tuc mine. It comprises a useful workable area of 12 hectares. Mining is done by forming a single step 25 meters long without previous removal of the superficial barren soil. The large stones are separated from the earth to be washed and are piled in the center of the excavation over a rich place to avoid cost of transport. The ore, often mixed with sterile materials, is carried away to be washed in baskets containing an average maximum of 2 kilogs. Two sluice boxes of the old Malacca type are employed. They are badly maintained and managed, a large quantity of fine ore rich in cassiterite being lost. The ore, still mixed with quartz and magnetite, is reduced in cupola furnaces, where the excess of silica to scorify makes the operation long. Not more than 1 kilogram of tin is produced per coolie per day. The tin is of excellent quality, thanks to the small amount of wolfram and mispickel. It is run in pigs weighing 25 kilos., which are sold at 3 to 3.50 francs per kilogram to the Chinese of the frontier. The Syndicat Francais Indo-Chinois intend to work a tin mine northwest of Cao-Bang. Stanniferous deposits are also to be found at Laos and Pak-Hin-Boun—a cassiterite in contact with ferruginous ore. At Yunnan the Chinese work stanniferous deposits similar to those of Cao-Bang.

MADAGASCAR.

Consul Hunt of Tamatave, Madagascar, furnishes a decree issued by the President of the French republic on June 23, amending a decree issued on June 3, suspending all prospecting for precious metals and precious stones on unclaimed lands in Madagascar. The effect of this modification will be that requests for prospecting permits may be received and registered by the mining department, which registration will simply maintain priority rights until the promulgation of a new decree amending the mining laws of February 20, 1902. The modified decree issued by President Loubet follows: Requests for permits to prospect for natural deposits of gold, precious metals and precious stones in Madagascar, prescribed on the conditions of Chapter 2 of the decree of February 20, 1902, will be, notwithstanding the stipulations contained in the decree of the Governor General of Madagascar, dated June 3, 1905, received and registered, as is provided in Article 12 of the aforesaid decree, but will have no other effect than to establish the priority of the requests and the eventual rights of the applicants for the obtaining of permits to prospect in accordance with the dispositions of a new law to intervene in the matter. It will not be applied to these prospectors' permits until after promulgation in Madagascar of the said law. The decree of the Governor General of Madagascar, dated June 3, 1905, is amended in all that is contrary to the dispositions of Article 1 of the present decree.

MALAY PENINSULA.

Gold mining operations are limited to certain mines in Pahang and Negri Sembilan. In Pahang the result is unfavorable. The total export of gold in 1904 was 20,157 ounces. The quantity obtained during the year from actual crushings was in Pahang, 12,625 ounces from 54,961 tons, and in Negri Sembilan 2189 ounces from 3438 tons. In addition, 146 ounces were won from alluvial workings, and 2115 ounces from 11,350 tons of tailings by means of the cyanide process.

MEXICO.

The Mexican Government has appointed a commission to study and reform the laws regarding coal and oil. As the law stands now, these minerals go with the land, and the land is owned in immense tracts generally by men who know nothing of these minerals, and the development of these industries is retarded. The plan of the Government is to segregate oil and coal from the land and put them in the same position with gold, silver, copper and other metals, which can be located by anyone on private lands. The commission is composed of J. L. Requena, Rodolfo Reyes, E. Martinez Baca, Joaquin Rounds and M. Ortega of Espinosa. As land stands now, its owners pay practically no taxes and they will resent anything which interferes with their prerogatives. The method of treating coal and oil will undoubtedly call for a tax on the lands which contain them, giving the land owners the first right to locate, and paying taxes is something a big Mexican land owner is unaccustomed to.

During the fiscal year 1904–5 the Department of Fomento issued 2840 titles to mines in the republic, covering 45,797 hectares of land, equal to a fraction over 113,164 acres. Of these titles, 1232 were issued in the half year from July 1 to December 31, with 19,690 hectares of land, and 1608 titles, covering 26,107 hectares, in the half year from January 1 to June 30, showing that 376 titles, with 6416 hectares of land, more were issued in the second half of the fiscal year than in the first half.

The following dividends were paid by Mexican mining companies during July, 1905: Dos Estrellas $90,000, Santa Gertrudis–Guadalupe $60,000, La Blanca, Pachuca, $50,000, San Rafael, aviadoras, $48,000, Santa Maria de la Paz $48,000, Amistad y Concordia $39,296, Real del Monte $25,540, Norias de Bajan $20,000, Soledad, aviada, $19,200, San Rafael, aviadas, $19,200, La Union Hacienda $15,000, Victoria, San Luis Potosi, $12,500, Providencia, San Juan de la Luz, $12,000, Sorpresa, aviada, $9600, San Francisco, Hac, $6000, Maravillas - San Eugenio $5000, Santa Maria de Guadalupe $5000, Turquesa, preference, $750, total $485,086.

American capitalists continue to search the mining districts of Mexico for profitable investment, and not infrequently promising mines, both old and new, are found, which are promptly equipped and sooner or later are placed on a paying basis. Good mines are to be had in Mexico, but no longer "for a song." The native miners have awakened to a realizing sense of the value of their mines, and to-day a good prospect or a developed mine in Mexico commands a price similar to that which it would bring if located in the southwestern United States. There are bargains occasionally, but as a rule a Mexican mine costs all the showing warrants these days.

Chihuahua.

At the Pinos Altos mines, in the Ocampo district, twenty stamps of the mill are ready to be started. The rest of the mill is undergoing repairs. The pan amalgamation process is to be substituted by concentration, with the cyanide process for the tailings. The pans are to be abandoned.——H. T. R. Cowell, manager of the Barranca de Cobre copper mines, 40 miles south from Bocoyna, on the line of the Orient Railroad, west of Minaca, has resumed operations on the mines. The concentrating mill will be started up next month. The management suspended all operations some months ago, but, now that the Orient Railroad will soon be running into Bocoyna, the mines will be within 40 miles of railroad transportation. The mines belong to a company which is controlled by the National Metal Co. H. P. Lewis, manager of the latter company, is expected to visit the mines.

Guanajuato.

The Guanajuato Reduction & Mines Co. has made final payment to the Casa-Rul M. Co. for the Veta-Madre mining properties at Guanajuato, and also mining properties in the district of La Luz. A 250-ton reduction mill and cyanide plant are to be put in before January 1, 1906.

Guerrero.

The Mexican M. & S. Co. has taken over the San Jose mines in the Taxco district and will operate a smelter there. L. W. Tatum of Cincinnati is general manager and W. D. Budrow has been appointed superintendent.

Mexico.

R. B. Hutchinson, manager Concheno mine, near Ocampo, is to increase the capacity of the cyanide plant from 60 to 100 tons daily. An electric power plant is to be put in.

Sonora.

The Democrata Cananea–Sonora C. Co. at Cananea, P. F. Hook superintendent, which has been developing during two years past, having closed down the smelter with a record of production of 3,000,000 pounds of refined copper in the year 1903, is preparing to put in a new furnace with a daily capacity of 300 tons of ore, and resume production.

SOUTH AMERICA.

Colombia.

Consul Snyder of Bogota furnishes a copy of the law recently enacted by Colombia reorganizing the national monetary system, from which the following items are taken: The monetary unit and current money of the republic is the gold dollar, divided into 100 cents, 1.672 gram weight and 0.900 fine. The other gold coins are: Double condor, of the value of $20; the condor, of the value of $10; the half condor of the value of $5. There will also be silver coins as follows: The half dollar, value 50 cents gold; the peseta, value 20 cents gold; the real, value 10 cents gold. Each of the coins mentioned will be of 0.900 fine and the weight corresponding to its value, relative to the gold monetary unit. For the purpose of minting the silver and fixing the values of the coins, each gram of gold of 0.900 fine will be considered as equivalent to 33 grams of silver. For each $100 of gold put into circulation there can only be put in circulation $10 of silver. If the Government deems it necessary for smaller transactions it may also order the minting of fractional coins of nickel, copper or bronze, with sufficient aluminum, of the value of 5, 2 and 1 cents, and not to exceed 2% of the amount of gold in circulation. The paper money legally emitted by the old National Bank and by the departmental governments will continue to preserve its character of forced currency and its independent powers according to the following rules: 1. It is in the power of all classes of contracts or transactions, civil or commercial, be they official or private, to state freely any class of domestic money or foreign gold. 2. In those parts of Colombia where the legal medium of exchange is silver, this will pursue its free power in relation to the price the standard of gold may have in the market, and contracts may be freely made in said money. The national silver coins known as ancient money, as the pesos of eight-tenths, and the coins worn in use will be classed with the money of 0.835 fine for the purposes of changing same for the new national money. The Government is authorized to recall, whenever it may deem it convenient, all old silver money circulating in the country in order to change it for those expressed in the present law, in the proportion which corresponds to it according to its value. The coins thus taken up and those received in the national treasury will be recoined in the mint. Individuals, both native and foreign, are prohibited from importing silver money. Domestic or foreign moneys which may be introduced into the country will be confiscated.

Books Received.

"The Western Electrical Directory," with names of companies operating electric light and power plants and electric railways, with additional information, is published by the Blanchfield Pub. Co., Rialto Building, San Francisco, Cal.

Professional Paper No. 36 of the U. S. Geological Survey, "The Lead, Zinc and Fluorspar Deposits of Western Kentucky," by E. O. Ulrich and W. S. T. Smith. This is a detailed report on the geology and mining of this district and should do much toward opening up many undeveloped resources of the country.

As extracts from "Mineral Resources of the United States" the United States Geological Survey has published "Statistics of the Clay Working Industries in 1904" by J. Middleton; it deals chiefly with the pottery and brick and tile industries, and is largely tabular in treatment. And "Statistics of the American Iron Trade in 1904" by J. W. Swank.

The latest addition to the recent literature on cementing materials is a comprehensive summary on "Cements, Limes and Plasters," by E. C. Eckel. The author's sequence of treatment is based on a logical classification of cementing materials into two groups, the simple and the complex. The simple cementing materials includes all those which are produced by the expulsion of a liquid or gas, through the action of heat, from a natural raw material, and whose setting properties are due to the simple reabsorption of the same liquid or gas, and the reassumption of original composition. The author subgroups this into the hydrate cementing materials or plasters, manufactured by dehydrating gypsum, and the carbonate cementing materials, or limes and magnesia, manufactured by driving off CO_2 from limestone or magnesite. The complex cementing materials include those whose setting properties are due to the formation of new chemical compounds during manufacture, or use, the set cement differing in chemical composition from the raw materials from which it was derived. This includes the silicate or hydraulic cements, whose setting properties are due to the formation of silicates, and the oxychloride cementing materials whose setting properties are due to the formation of oxychlorides. In succession is detailed the composition, distribution and excavation of raw materials; the chemistry, machinery and methods for manufacture and the composition, properties and tests of the finished product. In contrast to L. C. Sabin's "Cement and Concrete," this is more essentially a treatise for the manufacturers. Stress has been laid in the discussion of manufacturing methods on the general chemical and physical principles which underlie these methods rather than on the details which differ at every plant and may change with each year. The data on labor, power and costs seem to be particularly reliable. It is published by John Wiley & Sons, New York City, and will be sent postpaid by the MINING AND SCIENTIFIC PRESS for $6.

Commercial Paragraphs.

THE Ogden Assay Co., 1725 Arapahoe street, has moved its office to 1540 Court place, Denver, Colo.—a more central and commodious place for their line of work.

PEARY of Arctic fame has sent to A. Leschen & Sons Rope Co., St. Louis, Mo., for some of their patent flattened strand Hercules hoisting rope for use in his Arctic explorations.

THE El Paso Con. G. M. Co., Cripple Creek, Colo., is installing a Jeanesville Iron Works triple expansion station pump 1000 feet below the surface; capacity 2000 gallons per minute. The pump is fitted up with Corliss valve motion; the steam cylinders are lagged with Russia iron, steam separators and power lubricators.

THE Mine & Smelter Supply Co., Denver, Colo., with branch houses in Salt Lake City, Utah, El Paso, Texas, City of Mexico, Mex., and office in New York City, has recently purchased the patents for the United States of the Wilfley concentrating table and Wilfley slime table from A. R. Wilfley and in the future will manufacture this line of machines. A. R. Wilfley will be associated with the Mine & Smelter Supply Co. as director of the company and consulting engineer.

Personal.

W. T. McDONALD, of Chinipas, Mexico, is in New York City.

W. E. SHARPS is manager Kelvin reduction works at Kelvin, Ariz.

G. F. COLTON has been appointed manager Good Hope mine, near Searchlight, Nev.

H. B. MAXSON of Reno, Nev., has been elected secretary of the National Irrigation Congress.

OWEN DOYLE has succeeded R. B. Stanford as superintendent Ranch mine, near Columbia, Cal.

W. N. FREDERICK has been appointed superintendent Richfield M. Co., near Tuape, Sonora, Mexico.

JAMES FLEMING of Minnesota has taken charge of Last Chance mine at Maybert, Nevada county, Cal.

S. C. PRUNTZ has been appointed superintendent Bautista and San Rafael mines at Ameca, Jalisco, Mexico.

F. M. SMITH has been appointed manager, Helena, Montana, smelter of the American Smelting Securities Co.

A. F. WILLIAMS, manager De Beers Con. Mines, Ltd., will return soon to South Africa from San Francisco, Cal.

F. G. OWEN is to have charge of Mexican Petroleum Co.'s drilling operations in Ebano fields, Tamaulipas, Mex.

E. G. HADOW, manager Ferguson Mines, Ltd., Trout Lake City, B. C., is in London, England, on a business trip.

FRED BUTLER, superintendent Topaz gold mines at El Mico, Nicaragua, has been visiting Salt Lake City, Utah.

F. J. CLARK has been appointed manager Butterfly-Terrible mine near Telluride, Colo., vice J. F. Heating, retired.

PAT SHEEHAN of Butte, Mont., has succeeded J. A. Czizek, retired, as manager Lost Packer smelter at Loon Creek, near Custer, Idaho.

JOHN SHAW has resigned as foreman Iron Mountain mine, Shasta county, Cal., to take a similar position at the United Verde mine, Jerome, Ariz.

JOHN BLATCHFORD of Terry, S. D., has resigned as superintendent Golden Reward mine, and will take charge of mining operations at Kirwin, Wyo.

EMERSON GEE is in Los Angeles, Cal., from Sonora, Mexico, where he has been engaged in professional business, and is returning to Sonora and Sinaloa, Mexico.

J. F. CALLBREATH, secretary American Mining Congress, has returned to Denver, Colo., from a visit to Portland, San Francisco, Los Angeles and Salt Lake City.

J. H. TALBOT, formerly superintendent Riena de Oro M. Co., at El Tiro, has succeeded the late P. E. Murray as superintendent America M. Co., at Cananea, Sonora, Mexico.

E. E. ALEXANDER of Spokane, Wash., has been appointed superintendent department of mines and mining at Spokane Interstate Fair, which meets this year October 9 to 15.

J. D. KENDALL of London, England, consulting engineer Slough Creek Gravel Gold, Ltd., has been inspecting the company's drift mine on Slough creek, Cariboo, B. C.

RENSSELAER H. TOLL, of Mancos, Colo., is in Denver, Colo. He has resigned the superintendency of the M. Con. G. M. & Dev. Co., to attend to private interests and engineering practice.

THOS. KIDDIE has resigned as manager Tyee Copper Co.'s smelter at Ladysmith, Vancouver island, B. C., to accept the management of the Britannia Smelting Co.'s smelter at Crofton, Vancouver island.

E. B. BRADEN of the Everett and Helena smelters, H. B. Underhill, Jr., of the Selby smelter, and H. R. Rust of the Tacoma smelter, are the Western committeemen having charge of the interest of the American Smelting Securities Co. on the Pacific coast.

Obituary.

JOHN FEDERER, superintendent of the Modoc mine, died at Cripple Creek, Colo., August 22, of pneumonia.

WM. A. CAIN, foreman Standard mill, Bodie, Cal., was killed August 24 by falling on a revolving flywheel.

JAMES C. SAVERY, owner of the Cable mine, died at Cable Mountain, Mont., August 21, of heart failure. He was a pioneer in California, Idaho and Montana.

Trade Treatises.

A catalogue, entitled "Morgan Continuous Gas Producer," gives information concerning this rapidly developing industry. The application of producer gas to all operations requiring fuel for heating purposes is shown to be desirable economy. In tests made by Robt. W. Hunt & Co. an average efficiency of 92% is reported to have been obtained; 6x9, fifty pages, embossed cover, from the Morgan Construction Co., 40 Exchange Place, New York City.

Latest Market Reports.

SAN FRANCISCO, September 1, 1905.

METALS.

SILVER. — Per oz., Troy: London, 27¾d (standard ounce, 925 fine); New York, bar silver, 60c, refined (1000 fine); San Francisco, 60c; Mexican dollars, 48c, San Francisco; 46c, New York.

COPPER.—New York: Standard, $16.50; Lake, 1 to 3 casks, $16.50@17.00; Electrolytic, 1 to 3 casks, $17.00; Casting, 1 to 3 casks, $16.12½@16.17½. San Francisco: $16.50. Mill copper plates, $17.50; bars, 18@24c. London: £71 10s spot per ton.

Copper has made a further advance within the week, and according to expectation has touched the 17-cent mark for the best Lake metal. There exists at the present time an unusual condition in the copper market. The sellers are reluctant to make quotations, and the general feeling appears to be that no large orders out of the ordinary could promptly be filled by the producers. The threat of Thos. W. Lawson to raid the market has had no appreciable effect upon the price of the metal, as yet, nor is it likely to have. The industrial conditions of this country, and of Europe, are such that the present demand for copper must rather increase than diminish, and as it is apparent that the supply does not more than meet the demand, there seems little likelihood of the price going much lower at present. If, owing to a bear movement, the price of the metal falls, it will, without doubt, promptly recover. That the present price of the metal is maintained by the legitimate demand of the world's industries appears to be without doubt. Should a treaty of peace be signed by Russia and Japan there are those who think such an act would affect the market adversely, but the beginning of a new industrial life in the Orient would quickly tend to offset any temporary effect caused by the conditions which made a demand for copper imperative in the conduct of the war. True, Japan, and probably China, also, will soon be larger producers of copper than heretofore, but all of the metal they will produce for some time to come will be absorbed by their home requirements, even if their domestic output can supply the demand which a revival of industrial life must bring. For the present no material fall in price need be anticipated, or should such occur it is evident it cannot remain below 16 cents for any considerable length of time. Indeed, it seems quite likely to go above 17 cents. Its only dangerous competitor is aluminum, and the controlling interests of the copper market do not care to make this competition too sharp. The relative merit and usefulness of copper and aluminum is likely to fix the price of copper as long as present conditions prevail.

LEAD.—New York, $4.80; Salt Lake City, $3.50; St. Louis, $4.52½; San Francisco, $3.70, carload lots; 4¾c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5¾c; pig, $4.85. London: £14 8s 9d ℔ long ton.

SPELTER.—New York, $5.75: St. Louis, $5.65; London, £25 12s 6d ℔ ton; San Francisco, ton lots, 6¾c; 100-lb lots, 7c.

TIN.—New York, pig, $32.75@33.25; San Francisco, ton lots, 34c; 500 lbs., 35c; 200 lbs., 35½c; less, 35½c; bar tin, ℔ lb., 35@37½c. London, £150 5s.

PLATINUM.—San Francisco, crude, $18.50 ℔ oz.; New York, ingot, $20.50 ℔ Troy oz. Platinum ware, 75@$1.00 ℔ gram.

QUICKSILVER.—New York, $41.00@$41.50, large lots; London, £7 7s 6d; San Francisco, local, $38.50@39.00 ℔ flask of 75 lbs.; Denver, $42.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 32½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 23.00c; San Francisco, Plumbers', 100-lb. lots, 19.00c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb., .04c.

NICKEL.—New York, 55@60c ℔ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 33@37c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c ℔ lb.; 100 lbs., 35c; 1000 lbs. 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $14.85; gray forge, $16.00; San Francisco, bar, 3c ℔ lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, $21.00@$21.00; open hearth billets, $23.00@$23.00; San Francisco, bar, 7c to 12c ℔ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 7¼c; less than 500 lbs., per lb., 8c; in 25-lb. tin pails, ¼c ℔ lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LIME.—Santa Cruz, $1.35 country, $1.25 city ℔ bbl.

CEMENT.—Imported, $3.00@4.00 ℔ bbl.; California, carload lots, $1.80 f. o. b. at works; small lots, $2.10 ℔ bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

LUMBER.—(Retail): Pine, ordinary sizes, $24.00@5.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50@5.00; pickets, $21.00;shingles, $2.50 for No. 1, and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00@35.00.

NAILS.—This week the basic prices are: Wire, $2.77; Cut, $3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d, Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4d and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 13½c; Hallett's, 14½c; San Francisco, 1000-lb. lots, 14c; 300@500-lbs. 12c; 100-lb. lots, 13c.

BISMUTH.—Subnitrate, ℔ lb., $2.10.

BONE ASH.—Extra No. 1, 5@6c ℔ lb; No. 1, 4@5c.

BORAX.—Concentrated, 7@8c ℔ lb; powdered, 9@10c; fused, 25@30c; crystal, 7c.

CANDLES.—Spear Brand, 16 oz. adamantine, 40s., 11c ℔ set; 14 oz. adamantine, 40s., 10c; 12 oz. adamantine, 40s, 9c; 10 oz. adamantine, 40s, 8c; 16 oz. stearic, 40s, 12¾c ℔ set; 14 oz. stearic, 40s, 11½; 12 oz. stearic, 40s, 10¼c; 10 oz. stearic, 40s, 9½c. 100-case lots and over, ½c less. Not less than 50-case lots, ¼c less. Boxes of 20s, price ½c advance.

CAPS.—3x, $5.50@6 per 1000; 4x, $6.50@7; 5x, $8@8.50; Lion, $9@9.50, in lots not less than 1000.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c ℔ lb.; caustic soda, in drums, 3@3¾c ℔ lb.; Cal. s. soda, bbls., $1.10@1.20 ℔ 100 lbs.; sks., 90c@$1.00; chlorate of potash, 12@13c; nitrate of potash, 6¾@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2¼@2½c; flour sulphur, French, 2¾@—c; alum, $2.00@2.25; California refined, 1¼@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 5½@5¾c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66% B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

CHROMIUM.—90% and over, ℔ lb., 80c.

COAL.—San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lot, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $8.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13.00 in sacks; Sunnyside, $8.50, long ton.

FIRE BRICK.—Domestic, carloads ℔ 1000, f. o. b., factory square, $25.00; soap and split, $22.50; arch and wedge, $27.50; skewback, $30.00; circle, $32.00.

FIRE CLAY.—Domestic, ℔ ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, $8.50.

FUSE.—Triple tape, $4.00 per 1000 feet; double tape, $3.50; single tape, $3.10; Hemp, $2.75; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 and up.

LITHARGE.—Pure, in 25-lb. bags, 9½@10½c ℔ lb.

MAGNESIUM.—Pure, N. Y., $1.60.

MANGANESE.—Black oxide, ℔ lb., 2¾@4c.

MERCURY.—Bichloride, ℔ lb., 77c.

MOLYBDENUM.—Best, $2.75 ℔ lb.

PHOSPHORUS.—American, ℔ lb., 70c.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1**, 50%, carload lots, 11¾c; less than one ton, 13¾c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2**, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

RED LEAD.—500 lbs. and over at one purchase, ℔ lb. 7¾c; less than 500 lbs., 8c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 55c.

SODIUM.—Metal, ℔ lb., $1.

TUNGSTEN.—Best, ℔ lb., $1.25.

URANIUM.—Oxide, ℔ lb., $3.50.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING AUGUST 15, 1905.

797,398.—SWITCH—W. J. Bell, Los Angeles, Cal.
797,168.—MINING SLUICE—P. Bouery, Weaverville, Cal.
797 170.—BORING MACHINE—L. Brodt, Berkeley, Cal.
797,171.—FRUIT WASHER—A. Cerruti, San Francisco.
797,097.—ADVERTISING CURTAIN—F. C. Chapman, Los Angeles, Cal.
797,405.—LINOTYPE MOUTHPIECE—R. Collins, San Francisco.
797,177.—DISK PLOW—W. S. Cook, San Jose, Cal.
797,187.—CAR SIGNAL—F. Ensign, Los Angeles, Cal.
797,195.—DRIFTING TOOL—H. D. Gould, Hood River, Or.
797,196.—DRIFT PLUG—H. D. Gould, Hood River, Or.
797,108.—SAW HANDLE—O. C. Hanson, Eureka, Cal.
797,279.—GAME BAG—L. W. Harpham, San Francisco.
797,109.—DREDGER—M. C. Harris, San Francisco.
797,057.—BALE TIE TIGHTENER—C. A. Hartmann, Hoquiam, Wash.
797,114.—AMBULANCE—W. R. Hill, Sacramento, Cal.
797,004.—COAL BUCKET—J. D. Isaacs, Oakland, Cal.
797,206.—CARBURETOR—H. L. Jessen, Oakland, Cal.
797 146.—CENTER BOARD—V. L. Ogidinssen, San Francisco
797,072.—BICYCLE SADDLE—H. M. Perkin, Los Angeles, Cal.
797,533.—MOTOR CARRIAGE—R. M. O. Phillips, Los Angeles, Cal.
797,223.—SWIMMING APPARATUS—C. P. Randolph, Oceanpark, Cal.
797,226.—STOVE—E. H. Richardson, Ontario, Cal.
797,230.—INJECTOR BURNER—A. C. Rush, Los Angeles, Cal.
797,465.—CLAMP—J. G. Sloberg, Oakland, Cal.
797,088.—PASTRY KNIFE—F. A. Tobler, Los Angeles, Cal.
797,478.—COFFEE FILLER—E. A. Weil, Sacramento, Cal.
797,164.—DUMP WAGON—R. E. H. Wurdisch, San Francisco.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

SHOE LACE FASTENER.—No. 797,743. Aug. 22, 1905. John A. McCoy, Sisson, Cal. The object of this invention is to provide a neat, simple and practical means for securing the end of a lacing without the tying of any knots. It consists in combination with a shoe having a lacing opening, of an eyelet secured to one side of the opening, said eyelet composed of a shank and a head, said shank having an opening through it for the lacing and having a longitudinal slot, and said head being made concavo-convex with its convex side presented outwardly and its peripheral edge normally in contact with the shoe upper, said head, also, radially slotted from its center outward, and with said slot arranged coincident with the slot in the shank and the walls of said radial slot turned outwardly at the entrance to the slot to permit the unobstructed passage of the lacing when winding the latter upon the shank portion interior to the concaved portion of the head.

WINDOW TIGHTENER.—No. 797,767. Aug. 22, 1905. G. H. Dyer, San Francisco, Cal. This invention relates to a device which is designed to prevent the rattling of windows and maintaining them substantially tight. The device consists of an inclined plate to be fixed to one of the parts of a window, a plate to be fixed to a companion part of the window, a pin mounted in the last-named plate, and a roller mounted on said pin, said roller having a slot extending radially from each side of its center and through which slot the pin passes whereby the disk is slidably mounted relative to the pin and the inclined plate.

JAR FASTENER.—No. 797,711. Aug. 22, 1905. E. Abramson and E. O. Bennett, San Francisco, Cal. E. O. Bennett, assignor of whole interest to E. Abramson. This device comprises two wire loops having inwardly projecting and horizontally curved hook members, each adapted to embrace a segment of a jar, said members having their inner ends overlapping and provided with eyes, and an operating lever formed of a single piece of wire, having its ends forming inwardly extending pintles adapted to enter the eyes of the hook members, said lever having, also, at points between its pintles and the outer end, eccentric portions located to one side of the pintles and adapted to fulcrum on the cover of the jar, and such details of construction as are necessary to produce the required result.

SCENES NEAR TOKAR, EAST NUBIA, IN THE SUDAN, AFRICA. (See Page 175.)

The Ubiquitous Mining Engineer.

In these days of strenuous industrial development, no portion of the earth's surface seems to escape the inquiring, investigating proclivities of the mining engineer. He is found everywhere that mineral is known in commercially profitable quantities, and often seeks for it where it is not. The odds and ends of earth's dark places—the terra incognitas—are each being subjected to that prying inquest for mines and mineral deposits. It is but a few years since the mineral resources of China were little known to the outside world. To-day the mining engineer is there in numbers, and China's mineral industry seems likely to grow into surprising prominence. The Arctic regions have become almost as well known as others of the earth's vast sparsely settled provinces, and that mostly within the last ten years, all due to mining development, and now attention is being turned to the Antarctic region. Not only are these remote and scarcely known lands being invaded by the mining engineer, but attention is being also directed to some of the oldest known regions of the earth. On this page are presented nine illustrations of a country which, in the early history of the world, was on the confines of a land noted for its high civilization—east Nubia, in the Sudan, Africa, overlooking the Red sea. The earliest civilization of the earth flourished in the countries about the Red sea, in Egypt, Arabia and immediately surrounding territory, and now, after 6000 years, the modern mining engineer invades the wilderness of the Sudan in search of mining possibilities. On page 175 is given some of the recent experiences of an engineer in that desert land. That east Nubia was ever settled by a civilized nation is not known to be a fact, but it has for ages been the land of roving Arabs, and there are numerous towns and villages scattered throughout the region. It would seem from the report of the engineer that the copper prospects in that section are not particularly promising, though with development something more alluring may be discovered.

From Silver to Copper.

Among the first mines discovered and developed in the Butte district of Montana were those of the "Rainbow Lode." Noted among the early producers were the Alice, Magna Charta, Moulton and Lexington. Some of these were opened as early as 1876. The croppings were siliceous, mineral stained and attractive to the prospector, as the red iron and black manganese oxide gave them an appearance of carrying values in precious metals, which they did. Both gold and silver were found in paying quantities, and the mines of the Rainbow Lode became famous almost before the great copper mines of Butte were known. The lode consists of a vein system in which the vein upon which the Alice mine is located is the most prominent. Many millions of dollars in gold and silver have been taken from the lode and rich placers were found in the gulches below the outcrop. As depth was attained, the oxidized ore gave place to the sulphides of iron, lead and zinc; but little is said in early reports on the district about the occurrence of copper in these ores. An analysis made of ore taken from the lode in 1878 indicated the presence of gold, silver, lead, zinc, iron and sulphur, but copper is not mentioned. It is the more interesting, therefore, to note that the Lexington mine, which has recently come into the possession of F. A. Heinze, is now being worked for copper, and is said to be producing at present 50 tons of copper ore daily. If the Lexington becomes a copper producer there is a reasonable probability that the numerous other mines in this same system of fissures may also become copper mines; also, probably, heretofore no one has ever thought of them as such.

There are numerous instances of mines recognized as producers of gold, silver, lead and zinc ores, but which were not considered as having a possible value for copper, that with depth have become valuable for their output of copper ores. Notable instances are the silver mines of Cerro de Pasco, Peru; Horn Silver mine at Frisco, Utah, noted as a lead-silver mine, and some of the mines of Bingham canyon, Utah. These instances might be multiplied many times, but a sufficient number of important occurrences have been noted to indicate the possibilities which lie in so-called worked-out mines. In some districts zinc replaces iron and lead sulphide to a great extent, with increasing depth, but it would now seem that it is a possibility that copper, in its turn, may displace the zinc. Copper sulphides are the most readily dissolved and altered of the base metal sulphides, and the metal is carried away in solution to be redeposited elsewhere, often forming a zone of enrichment, but it must always be remembered that a normally very low grade of copper ore may result in the formation of a zone of greatly enriched ore—sulphide, or oxide, or carbonate, and that this forms no basis of estimate of normal values below. This new development in the Butte district of Montana will probably stimulate the exploration of the old mines on the silver belt for copper.

Experimental Metallurgy.

The hope for success in the commercial application of metallurgical processes is in nearly every case based on well-known chemical reactions. Tests are made in the laboratory, necessarily on a comparatively small scale, and on the result of these small-scale tests large plants are sometimes designed and built. Unfortunately, the conclusions which are reached as a direct result of the laboratory experimentation are not always borne out in a satisfactory manner when the process, which has been worked out along more or less elaborate lines, is applied on a commercial scale. There are several reasons for this, but the most common one is, no doubt, insufficient or improper experiment—the conducting of the tests along lines which cannot be economically duplicated on a working scale. Another cause for failure is occasionally found in the fact that the experimenter has wedded a "hobby." He has a certain elaborate scheme along the lines of which he determines to operate, regardless of the character of the ore. He is sure of the success of his pet process, if only the ore can be adapted to it. It is more particularly in metallurgical operations by wet methods that these mistakes are made, for in smelting there are certain laws of chemistry which can only be violated within definite limits, and, passing these limitations, the disaster is so pronounced that all will know who chance to be in the vicinity. Too much coke, too little coke, too much or too little of any of the essential elements in the charge, and something of a very pronounced nature occurs. An expert may be able to overcome the difficulty, and the refractory furnace be brought back to a normal condition by the application of the proper remedy. He may increase or diminish the blast, employ more or less fuel, add or reduce the silica, iron or lime. He is able to tell by the physical appearance of the inside of the furnace and a study of the charge what is wrong and make the necessary correction.

Not so, however, in wet processes. A weak solution looks the same as a relatively strong one. The rate and amount of extraction can only be determined by careful test. The pulp looks the same after treatment, generally, as it did before. No rule of thumb is applicable here.

No metallurgical process exemplifies the conditions here referred to better than the cyanide process. Cyanide solutions have been recognized as solvents for gold for more than 150 years and some historians say that a solution of potassium cyanide was known to dissolve gold in the Middle Ages. This knowledge had been made use of by electroplaters for many years prior to the first metallurgical patent granted for a process to extract gold from its ores by this method. The first patent for this process was issued February 5 and March 12, 1867, to Dr. J. H. Rae of Syracuse, N. Y. Since then there have been issued patents on modifications of the process and methods of applying it in great number.

The simple cyanide process, as described by the MacArthur-Forrest patents, is applicable to those ores which are free from mineral substances which have a tendency to foul the solution or to decompose the cyanide present, and in which the gold is in a fine state of division and so exposed that the metal may readily come in contact with the solution. Ideal conditions have in some instances been found in old tailings dumps which have for many years been exposed to the decomposing action of the winds and rains, by means of which the sulphides, if originally present, have become oxidized and have left the ore in a fit condition for the application of the process in its simplest form.

There are many ores which are not amenable to the cyanide process without some preliminary treatment. This may be amalgamation for coarse gold; concentration for sulphides, or probably roasting may be necessary to render the ore susceptible to cyanidation. There are instances, however, where a high percentage of the values may be extracted by old and well-tried means, which, if properly applied, will render the cyanide process unnecessary.

Take as an instance gold quartz ore carrying about 1% sulphurets, mostly pyrite. The gold is both coarse and fine, and when freed from its matrix amalgamates readily. Concentration follows and auriferous sulphides are collected for treatment by chlorination or smelting. This ore should, by proper milling, yield 95% of its values, or possibly more, but only 80% is obtained. Evidently something is being done which should not be done, or something remains undone which should be done. An investigation is made and it is found that the screens, though nominally 30-mesh, are really 24 to 26. A 30-mesh screen is tried and the saving is raised from 80% to 85%. A 40-mesh screen is tried, and the tailings after the machines show the extraction to have been increased to 90%. This suggests that gold had previously been lost in the uncrushed grains of quartz. A test of the tailings from the 30 screens and an assay of the coarse sands prove this surmise to be correct. A careful test of the tailings below the concentrators shows that there still remain some values in the form of sulphides which have passed the machines. A classifier is introduced, the coarse sands are sent to one machine and the fines to another, and the result is a further saving of 5%. The ore as it reaches the mill is worth $10 per ton. By a rational process of crushing, classifying and concentration a saving of 95% is effected, and the tailings are too low grade to cyanide. It is surely not to be recommended in such a case to change this simple and highly satisfactory process for one which will leave sufficient values in the tailings to pay to treat by the cyanide process.

It may be claimed that by reducing the mesh of the screen the capacity of the mill is cut down. This would be a natural result of introducing a finer screen, but this may in most instances be offset in a measure, if not altogether, by lowering the discharge, which in itself would have a tendency to increase the crushing capacity of the mill.

IN the operation of the cyanide process there appears to be a tendency to revert to the original practices, and to discontinue the use of the numerous modifications introduced within recent years. The entire process, after all, is based on simple facts—the reactions which take place when a weak solution of potassium cyanide comes in contact with fine gold in the presence of oxygen. So many side issues have been introduced into the process in the effort to solve some unusually difficult metallurgical problem, that these modifications of the process are sometimes employed from the beginning instead of the more simple process of straight cyanide of potassium solution. No metallurgical process in use requires the exercise of a greater amount of common sense than the cyanide process, but this is not always a pronounced feature of the efforts made in its application.

THE note on cyaniding raw sulphides in South Africa which appears elsewhere herein should attract the attention of those who have similar problems to solve. In this case it appears that the element of time—forty days—was an important factor. More experimentation along these lines might result in valuable information. As usual, it is not unlikely that much depends upon the ore. Raw treatment may be a success at one mine and, for some unknown cause, not successful at another. In all cases, however, fine grinding appears necessary. In West Australia raw ores are successfully treated at some of the mines.

CONCENTRATES.

QUARTZITE is often gold-bearing. Copper, lead, zinc and other mineral also occur in quartzite, and such ores are sometimes rich.

ORDINARILY an estimate of 1 cubic foot of water per horse power per hour is sufficient to generate steam in a boiler where a modern engine is employed.

A CHANGE in the locality where water, which has been appropriated, is used does not invalidate the right. A ditch or flume may be extended and the water used at another place.

SHAKING screens always clear themselves more quickly and afford larger capacity than screens which are stationary. Impact screens operate in the same manner as shaking screens.

A 10-STAMP BATTERY of 1000-pound stamps will weigh, including all iron and wood work, guides, etc., about 34,000 pounds. The mortars weigh from 5000 to 6000 pounds, and certain special designs even more.

IN quartz veins limonite and hematite almost invariably change to sulphides in depth. Large masses of hematite, however, do not always change to sulphides, as, for instance, the large iron deposits of Michigan and Minnesota.

THE roasting of sulphide ores not only volatilizes or oxidizes the sulphide, arsenical and antimonial compounds present, but also renders the ore more porous and better fitted for leaching or other metallurgical treatment.

FOR settling and classifying, tanks having vertical sides and conical bottoms, sloping at an angle of about 50° to the horizon, are believed to be of great practical value. Some excellent work is being done with tanks of this description.

ORES consisting largely or wholly of talc, and which give considerable difficulty in crushing to proper fineness, sometimes can be handled more satisfactorily if first calcined. This dehydrates the rock and it is more easily reduced to powder.

A DYNAMO can usually without material alteration, or without any at all, be employed as a motor. Motors were introduced for convenience and for particular purposes. A single dynamo may run any number of motors within the range of its electro-motive force.

SOME engineers require that only clean, sharp sand shall be used in cement mortar. Experiments made by competent engineers have indicated that sand with clay or loam up to 15% results in forming a stronger mortar than where clean, sharp sand only was used.

THE deepest gold mines in the world are at Bendigo, Victoria, Australia—over 4000 feet vertical. The deepest vertical shaft in California at the present time is in the East shaft of the Kennedy mine near Jackson, which is down 2800 feet and sinking at the rate of 60 feet per month.

WHERE a party enters into an agreement to work for another party for an indefinite term, and a date is stipulated at which time the money shall be paid for such services as may have been rendered, the money is not due before such date, and there would be no hope of collecting the money sooner by filing a labor lien.

WHETHER wet crushing has any advantage over dry crushing should be determined by the character of the ore and the method of treating it after crushing. In a few mills the ore is crushed in cyanide solution in the battery, and the ore subsequently amalgamated. The process appears to have nothing in particular to commend it.

WHERE ore passes in mines are of a height exceeding 100 feet, and suitable rock (slabs from the walls) cannot be obtained to build strong walls in these raises, or ore passes, they may be timbered with good sized poles laid longitudinally of the vein, the ends abutting on the ore pass. The wear on timbers laid in this manner is much less than where the sticks are laid at right angles to the walls.

WHEN wall plates in an inclined shaft get out of level through carelessness in placing, or by reason of being shifted by blasting and not reset in proper position, the error may be corrected by shortening the posts for two or three sets on the lower side; but in doing this care must be taken to keep the alignment perfect, or the shaft will take a "wind" and cause much trouble in the future.

QUARTZITE may be usually distinguished from quartz by its structure. The latter is massive and the former has a granular appearance. Quartzite is a metamorphic sedimentary rock in which the grains of sand have been cemented by silica. It occurs from fine to rather coarse grain—that is, a texture in which the granules of the original rock may be readily seen without the aid of a magnifying glass. Massive quartz in veins is sometimes fractured by pressure so as to resemble quartzite, and it may then be difficult to distinguish it from quartzite without the polarization microscope, but generally the two may be easily told one from the other.

THE amount of water usually estimated as necessary for coarse concentration, as in the case of native copper from its gangue, or sulphide copper ores from its matrix, is about 4000 gallons to the ton of ore crushed, but the amount really depends upon the character of the ore, that containing clay requiring more than where the gangue is quartz, calcite or some other brittle mineral.

SECTIONAL MACHINERY—pans, mortars and other parts in which quicksilver is to be charged and ground or stamped—must be put together with the greatest possible care, or leakage is sure to result. The sections come planed and every effort is made by the makers to have the parts fit perfectly, but much depends upon the manner of fitting these parts together when set up at the mill.

ZINC precipitation boxes are made in long units divided by double partitions into sections each about square. They are also made in individual boxes, and in some works half barrels are used for the purpose. It is not apparent that one kind of box has a great advantage over any of the others. The single boxes have the possible advantage of being more easily cleaned and moved about when necessary.

THERE are a great many patents issued for modifications of the cyanide process in the United States. Some of these patents cover metallurgical features—some are on the mechanical devices employed—and it would be impossible to state whether it would be necessary to pay a royalty on the use of the process or not unless all conditions were known, and even then it might require a suit at law to settle the matter satisfactorily.

GOLD ORE which consists largely of hydrated iron oxide (limonite) is often difficult to amalgamate, either on plates or in pans. In such ores the gold is usually very finely distributed, the ore slimes bady on crushing, and these two conditions render amalgamation unusually hard to satisfactorily accomplish. Burning such ore aids somewhat, but it is better to treat it by chlorination, if the values be high enough to justify it.

THE lowest grade of copper ore which can be worked depends entirely upon the conditions surrounding the proposition. In the Lake Superior region some of the mines pay which carry not to exceed 1% metallic copper. In British Columbia at one mine copper ores are mined and worked at a profit which do not carry more than $5 per ton. This proposition is so variable that no definite answer can be given to a question of this kind.

THE Cripple Creek ores from the superficial portions of the veins—the oxidized ore—are treated by cyanidation without roasting, but that from the deeper levels where the ore has not been affected by oxidation is roasted prior to treatment. The telluride ores of the Black Hills, occurring in the oxidized zone, yield a high percentage of their values to cyanide, but the unoxidized blue ores are not found so amenable to this treatment.

THE cost of electric power, where supplied by distributing companies, is usually influenced by the cost of other power which may be available. The competitors to electric power are commonly water, steam, gasoline or similar engines and competing electric lines. The price ranges from $3.50 per horse power per month under favorable conditions to $12 or over where the expense of generating power is high and where competition is not very active.

WITH machine drills having about 3-inch pistons and operating under about 90 pounds pressure, 45 to 50 feet of holes in an eight-hour shift is considered a good day's work in hard rock—greenstone, granite, quartz-porphyry or other similar hard, massive and unaltered rock, that is not softened by weathering or decomposition, for some hard and tough rock becomes very soft on being subjected to alteration by atmospheric or chemical agencies, such as solfatara.

SOME States require that a person taking up a water right shall make affidavit to such fact before a notary public. The water right should also be recorded, and work begun on the dam or ditch within a "reasonable time," and continued with "reasonable diligence." The exact meaning of the terms reasonable diligence and reasonable time is not made clear by the law, and it would require the opinion of a court to determine what, under existing conditions, would be reasonable time and diligence. If a person has located a water right and has allowed his right to lapse, he alone or with another may again locate the right, if in the meantime it has not been taken by another.

THE magnetic needle is strongly influenced by an electric current. If a magnetized needle be held over a horizontal copper wire through which no current is passing, and the wire is carefully adjusted to coincide with the direction of the needle, and a current of electricity is passed through the wire, the needle will at once swerve to the right or left to the extent of nearly 90°, depending on the strength of the current. As soon as the current is shut off the needle will swing back to its former position, pointing to the magnetic pole. If the direction of the electric current be now reversed, by changing the connections of the wires, the needle will again be deflected from its true position, but in the opposite direction. If the needle be held beneath instead of over the wire, the deflection of the needle will be directly opposite to those of the first trials. The distance between the needle and the wire also is a factor—the nearer the wire the greater the deflection for given strength of current.

THE velocity of water flowing in a stream is not uniform throughout its entire cross section. It has been found by careful experiment that the average velocity of a stream is from 0.81 to 0.93 of its maximum velocity. At a point about midway between the surface and the bottom of the current the velocity is close to 0.915, and on the bottom about 0.83, of that at the surface being more or less according to the character of the bottom—whether smooth or rough. To find the volume of water flowing in a stream, multiply the area of cross section in feet by the velocity in feet. This will give the cubic feet passing during a stated interval, either per second or per minute, depending on the length of time given to velocity. Thus if a stream be 5 feet wide and 4 feet deep, and the maximum velocity be 30 feet per minute, the volume of water flowing in the stream will be approximately $30 \times .915 \times 4 \times 5 = 549$ cubic feet per minute, or 9.15 cubic feet per second. It is likely to give greater accuracy if the velocity of the stream be taken for a minute or even longer than for a shorter period.

WHEN unpatented mining claims are forfeited to relocators because of failure to perform the necessary assessment work, any buildings, cabins, machinery or other fixed improvements become the property of the party relocating the claim. As a matter of safety the relocator should state that it is a relocation of a claim, and he should place the location of record, whether the State laws require it or not. It is not necessary to bring suit to quiet title, but the former proprietor may file an adverse, when the relocator must prove that the claim was subject to relocation at the time the relocation was made. It does not appear that a pipe line and giant, in place on a line thus relocated, would be excepted from the improvements which pass to the new proprietor, even though the pipe line were not tied to the ground or to trees, etc. Pipe lines are only so tied where necessary to render them secure as to slopes. The original locator having failed to comply with the law—the condition of the statutes which requires the performance of certain acts to insure his title to the ground—he is an intruder and no longer has the color of title to the property. Although the statute does not define what property shall be considered as fixtures, it is only reasonable to include a pipe line in such improvements, while a wheelbarrow or a portable forge might not be properly so considered. The relocator may legally enter upon the use of such improvements as were left by the former proprietor, and may do so at once.

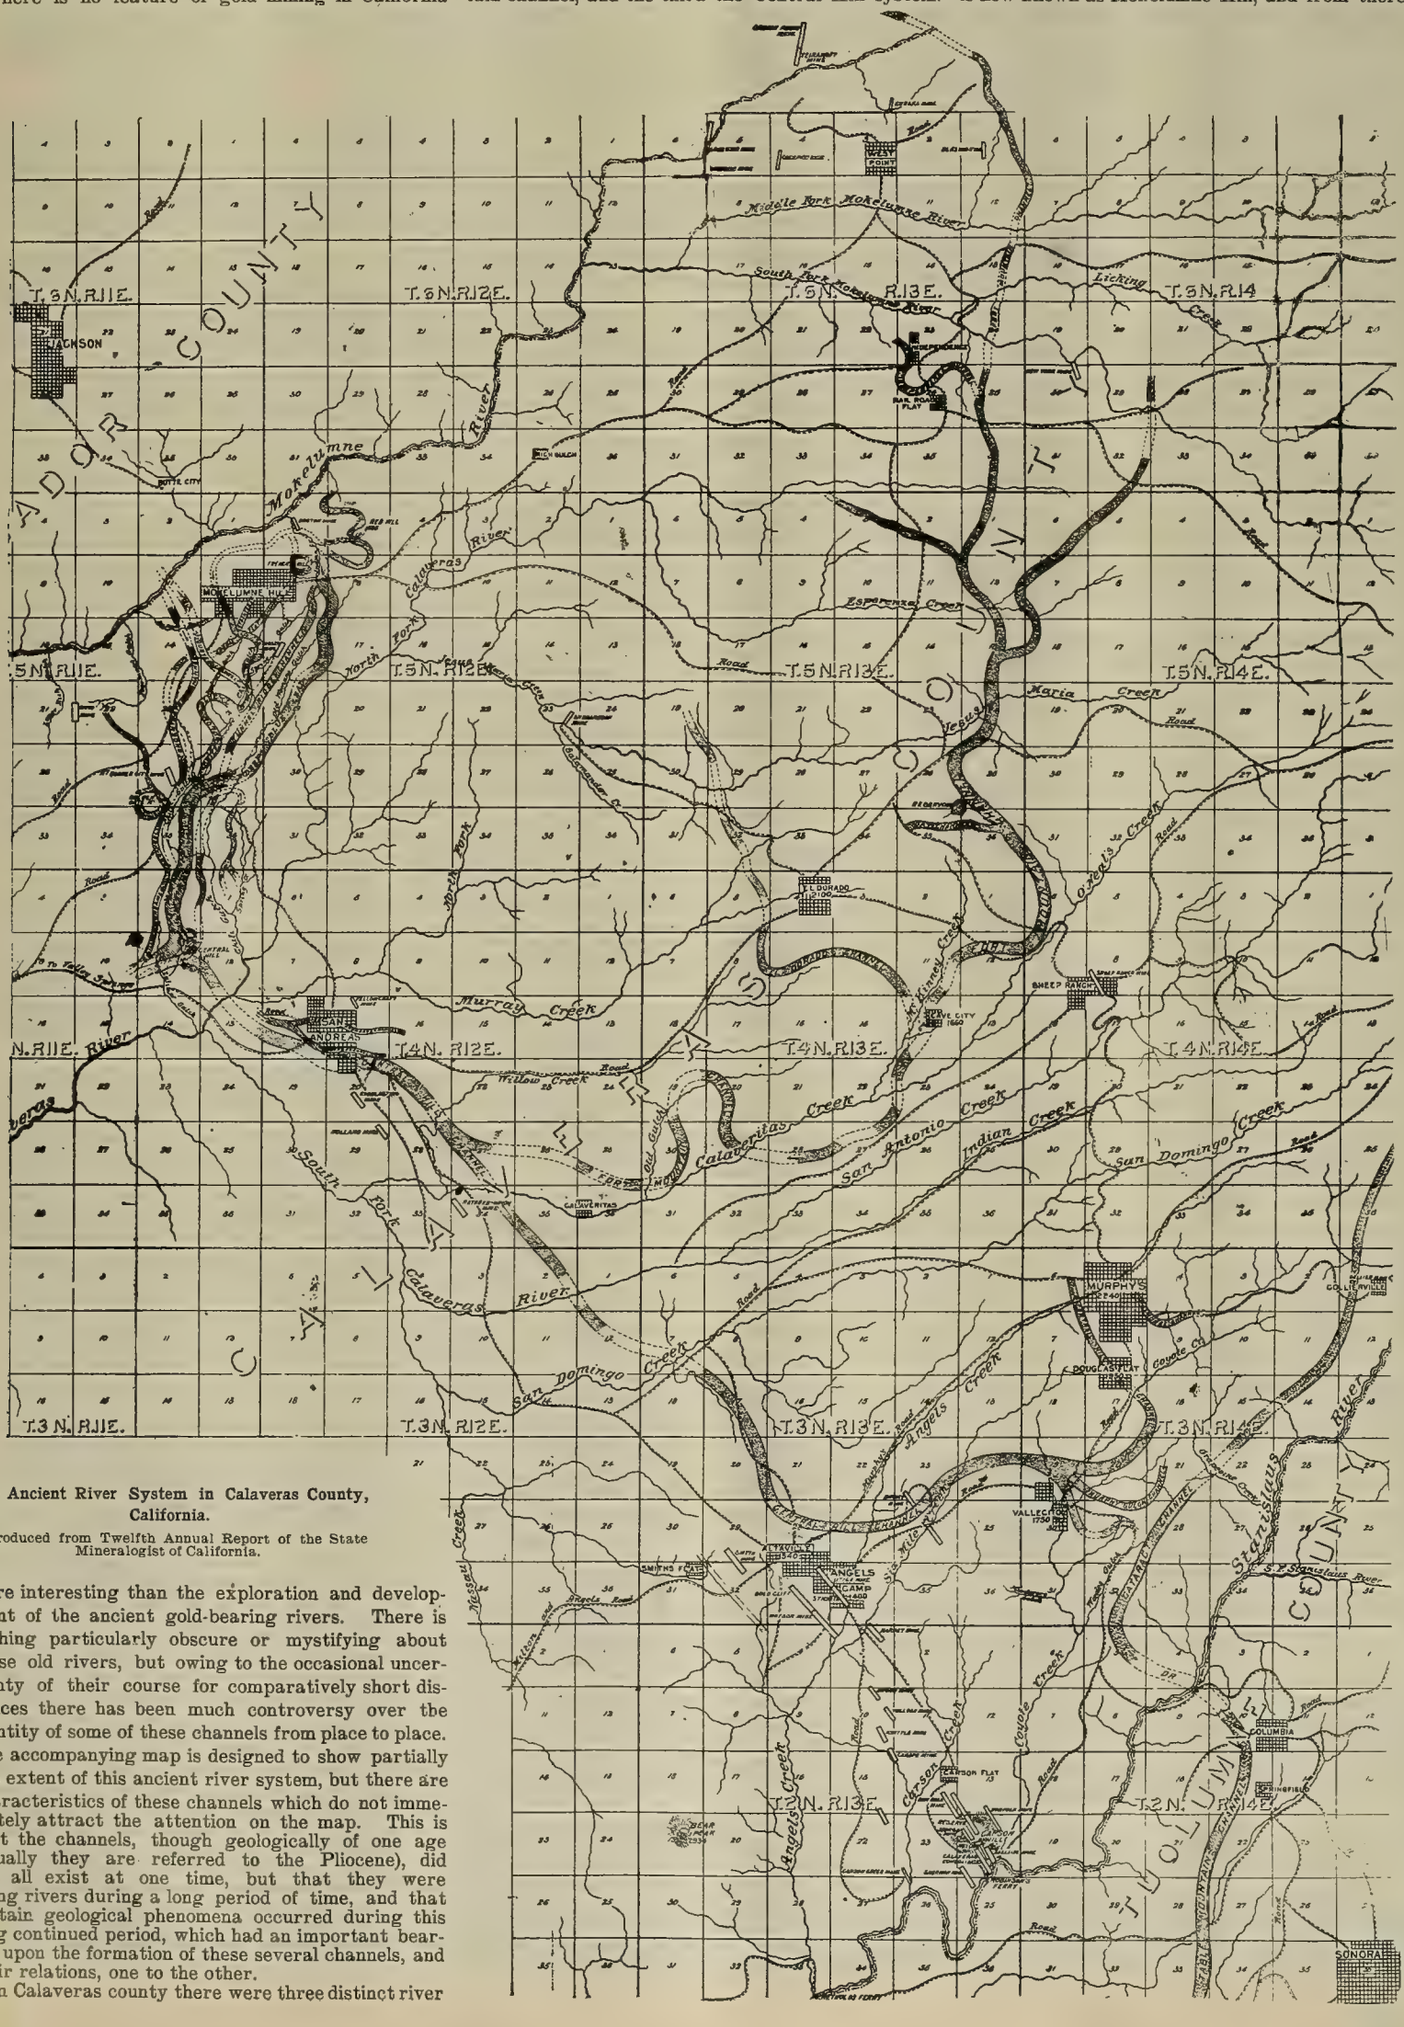
THE principal kinds of rock are sedimentary, eruptive, metamorphic, and those resulting from chemical deposition. Each of these is divided into numerous classes. Among the sedimentary rocks are sandstones, shales, calcareous sandstones, sandy limestones, and various gradations between purely argillaceous and purely sandy rocks. Under this head also come grits (coarse sandstones) and conglomerates. The eruptive rocks are chiefly of two kinds: (1) those intruded from below in the form of roughly round masses, or bosses; in elongated sheets (dikes) and in flat sheets (sills), and none of which reach and flow out on the surface, and (2) those which do reach the surface and spread out in sheets—volcanic or effusive rocks. In the latter class is also included the fragmental rocks resulting from the recementing of volcanic debris thrown out from volcanic vents, such as tuffs, agglomerates, etc. Limestones are for most part in a separate class, but may be considered as sedimentary. They are formed in various ways. The principal sources of limestone are from the secretions and the shells of minute organisms in the ocean, and from the deposition from calcareous springs. Metamorphic rocks include every class of the above, when they have been changed from their original condition. This change may have been slight, or may have progressed to such an extent as to have entirely changed the rock from its original condition to a new one. (The decay of rocks, due to weathering, is not metamorphism.) By pressure and movement, and the heat developed in the operation of these processes, the individual constituents of a rock are changed, passing over to an entirely different lot of minerals and the formation of a new rock, not recognizable as having any resemblance to the original. Thus limestone may by metamorphism become marble, or it may be altered to pyroxene and the latter further changed to serpentine. These changes involve many chemical reactions, the removal of some of the original constituents and substitution of others with the introduction of still other foreign material. Sandstones may be altered to quartzite, or to mica schist, garnet schist, etc. Shales become hard slates, often with the development of coarsely crystallized minerals in the finer mass of the rock, such as garnets, chiastolite and other crystals. Metamorphism is a subject so involved that it would require a large volume to give a comprehensive idea of the great number of alterations, which individual minerals and rocks undergo.

Ancient Gravel Channels of Calaveras County, California.

Written for the MINING AND SCIENTIFIC PRESS by W. H. STORMS.

There is no feature of gold mining in California more interesting than the exploration and development of the ancient gold-bearing rivers. There is nothing particularly obscure or mystifying about these old rivers, but owing to the occasional uncertainty of their course for comparatively short distances there has been much controversy over the identity of some of these channels from place to place. The accompanying map is designed to show partially the extent of this ancient river system, but there are characteristics of these channels which do not immediately attract the attention on the map. This is that the channels, though geologically of one age (usually they are referred to the Pliocene), did not all exist at one time, but that they were living rivers during a long period of time, and that certain geological phenomena occurred during this long continued period, which had an important bearing upon the formation of these several channels, and their relations, one to the other.

In Calaveras county there were three distinct river systems taking their rise in regions several miles apart — the greater number originating in Amador county or even beyond the limits of that county. The map shows these three systems clearly—one the Mokelumne Hill system, the second the Fort Mountain channel, and the third the Central Hill system. The first is the most complicated and comprises at least ten separate channels, and there are probably one or two more not yet positively identified. These channels, mostly taking their rise apparently in Amador county, flowed in diverse directions toward what is now known as Mokelumne Hill, and from there by



The Ancient River System in Calaveras County, California.

Reproduced from Twelfth Annual Report of the State Mineralogist of California.

sinuous course in a generally southwesterly direction toward the valley of the Sacramento river.

The Fort Mountain system took its rise in Amador county, in the Sierra region, and flowed with its numerous tributaries in a southerly, and then a westerly, direction toward San Andreas, and about 4 miles west of that town joined the Mokelumne Hill system. The Central Hill channel had its origin somewhere northeast of the village of Murphys. There seem to have been several important channels in this system, some unexplored and practically unknown. For instance, about 1 mile southeast of Murphys a channel has cut directly across the Central Hill channel flowing in a southerly direction. This channel cut out 500 feet of the Central Hill channel, but little is known of it beyond this fact, and that where passed through by a tunnel driven to reach the Central Hill channel it was filled with coarse volcanic sand and was saturated with water.

In the vicinity of Douglas Flat and Vallecito there is a complex of ancient channels something like that at Mokelumne Hill, but the relations of these several channels are not fully established, nor can they be until further work is done and a systematic investigation carefully made of the entire district.

There is another channel system which originates in Calaveras county, in the region of the Sierra, above the Big Tree section, which flowed in a generally southerly and southeasterly direction into the adjoining county of Tuolumne, entering that county near the town of Columbia, and which, where worked, has been found usually to be rich in gold.

In Calaveras county alone there are more than 100 miles of these ancient stream beds. Of this about 25% has been removed by recent erosion; about 25% probably has been mined, and there still remains nearly 50% of these old golden rivers intact, awaiting the enterprise of the miner. It is this fact that gives these old river beds an interest beyond their mere existence. As a geological study there is nothing of greater interest, but this is enhanced by the possibilities of profitably mining these gravels, and recovering the gold which has lain in the old rivers for so many thousands of years.

When contemplating these ancient rivers and similar streams elsewhere it must be understood, and remembered, that the same natural forces which have formed the modern creeks and rivers were at work in Pliocene time, and the causes which produce familiar effects to-day produced similar effects at that time. Nature constantly strives to tear down the mountains to the level of the sea. The agencies which perform this work are the sunshine and rain, the wind and changes of temperature. The process is slow but never-ceasing, and in a long period of years a stream will cut a deep canyon into the hardest rocks. Where the stream contains much detritus and the volume of water is sufficient the erosion is more rapid than where the water is comparatively free from sediment and gravel. These are the first principles of erosion. A great mountain region will in time be reduced to a base level by erosion if nothing interfere to prevent it. When studying these ancient rivers these simple facts must be kept in mind, and a rational solution will be usually found for almost every perplexing problem which presents itself. It is at times difficult to identify certain channels when they are unexpectedly encountered underground in the development of another channel, but further development usually clears up a problem of this kind.

The most important economic feature of the ancient rivers lies in the fact that the tremendous erosion which produced these streams also freed the gold from the rocks and veins in the mountains, and the contents of millions of tons of ore was thus concentrated into a comparatively few narrow streams. Thus it will be seen that a country may produce only mediocre quartz mines, but by erosion make rich placers. There are numerous instances of this fact throughout the mining world.

The ancient river-forming period undoubtedly lasted for thousands of years. The gold was freed from the rich veins of this portion of the mineral belt of the State in Calaveras and Amador counties and was concentrated in the earliest system of rivers—channels of the first period. At this time began a period of volcanic activity which was spread over a wide region of the State, in both the Coast Range and the Sierra. Volcanic vents opened along and near the crest of the Sierra and volcanic debris poured out over the adjacent country. Ashes and mud covered the slopes and the accompanying violent rains swept the mud down into the gulches and canyons, often filling them, in time, to the brim and completely burying the gold-bearing gravels under the muddy flood. Following this outburst of volcanic rock came a period of quiet, and the erosive forces of nature continuing, another set of new channels was formed. These latter channels did not follow directly the course of the former streams, but conformed with them in a general way—flowing southwesterly, in a line normal to the general trend of the Sierra. In time these new streams reached the underlying crystalline bedrock and the gold-bearing veins were subjected, in places, to a second period of erosion. In some instances the later channels intersected the older channels, sometimes crossing and recrossing them, as shown on the map, in the neighborhood of Mokelumne Hill. The channels of the first period were cut out at these intersections and the contained gold went to help enrich the channels of the second period. Again volcanic activity played an important part in the economy of the golden rivers which were to yield up their gold in later ages, to the energies of civilization.

Once more the channels were filled with volcanic mud, sand and rocks, and then again followed a period of quiet and long-continued erosion. These alternating intervals of volcanic activity and quietude succeeded each other several times, always with similar results—the burying of the existing channels and the formation of a new system later, when the mud rivers had ceased to flow and the volcanic debris had settled into a semblance of firm rock or compacted sand. That there were long periods of freedom from volcanic outbursts is abundantly proven by the tremendous extent of the erosion which marked these periods. Great trees grew along the river banks, and with the coming of the next volcanic flow these trees were overturned or remained standing upright and were buried in the great volume of mud. The trunks of these ancient trees have been found in the course of mining operations, sometimes turned to stone; sometimes a hollow, cylinder-shaped hole in the indurated mud flow indicating where the tree formerly stood.

During all of this period of channel forming, with its variations, many of which are clearly indicated by a study of the several channels and their relations to each other, the entire Sierra region was slowly rising. This slowly moving uplift is supposed by some geologists to be in progress at the present time; but our lives or the history of the country are far too short to make conclusive such theories.

The rivers emptied into the great depression between the Sierra and the Coast Range—the great interior valley of California. At that time the valley was a vast fresh water lake. The sands, gravels and fine sediment from the ancient rivers during their several periods were carried down into this lake and spread out in fan-shaped flat cones in the estuaries formed at the mouths of the rivers. These deposits were essentially almost horizontal; but the beds formed at that time are now found raised above the interior valley along the eastern foothills and tilted toward the valley at a much higher angle than that produced by the deposition of sediment from a river into a large body of still water.

It is this long-continued uplift of the entire Sierra region that caused the comparatively rapid formation of this series of ancient rivers, for, with a constantly rising region, the streams kept up their grades and caused them to cut rapidly into the bedrock. As a stream approaches the base level of erosion—the level of the sea—its power of erosion and its ability to carry along with it the sediment, gravel and other debris, which are the most powerful factors in cutting and wearing away the bedrock, constantly decreases, until at sea level it is nil.

Having outlined the processes by which the ancient channels were formed, not only in Calaveras county, but in every other county of California where they may be found, it may now be proper to inquire more directly into the characteristics of the several channels.

(TO BE CONTINUED.)

THE Government of the Dominion of Canada has appropriated $15,000 for making experiments with the electric process of smelting ores and manufacturing steel at Sault Ste. Marie, and the Consolidated Lake Superior Copper Co. will furnish a building and dynamo capable of supplying 400 H. P. for four months free of charge. All kinds of ore will be experimented with, and important results are expected to be obtained. Great possibilities for Canada underlie the inauguration of a cheaper process for manufacturing pig iron and steel than is now in use. Ontario is dotted with ore bodies, the development of which is prevented by lack of cheap fuel. There is coal in the eastern and western parts of Canada, but the cost of conveying it to points where coke is needed for smelting purposes is prohibitive. On the other hand, there are a great many water powers throughout the Provinces of Ontario and Quebec where electricity can be developed and utilized. If the electric system proves to be commercially feasible, Canada is looking for the inflow of a large amount of capital and considerable mining development.

A METHOD to reduce the tendency of turbine wheels to burn out their steps is suggested in the Engineering News in the following: Cut across the bearing surface of the steps three or four deep grooves, radially. These grooves are of generous depth and width, say ⅜ and ½ inch, respectively. It would appear that their action is to allow free access of the water to the bearing surface of the step, aided possibly by a more or less energetic circulation through the grooves, thus keeping down the temperature. However it may be, the fact remains that the device is most effectual.

IN some of the Lake Superior copper mines occur native copper almost pure, and native silver also practically pure. As far as known these minerals are never found alloyed in these mines.

Cyaniding Silver-Gold Ores of the Palmarejo Mine, Chihuahua, Mexico.*

NUMBER VII.—CONCLUDED.

Written by T. H. OXNAM.

When treating charges containing the equivalent of 15 tons of dry slimes, usually four settlings and four decantations can be effected within the forty-eight hours of treatment, each decantation averaging about 22 tons of solution. Hence about 90 tons of solution are decanted in treating a 15-ton charge, and each decantation removes approximately 58% of the total solution present. Assuming the wash agitations to be perfect, the four decantations should then theoretically contain about 97% of the total values dissolved at the time the washing was commenced.

The settled pulp is discharged through the bottom valve and the 4-inch discharge pipe into the residues launder and is run to waste.

Table VIII shows the rate of settling per hour, determined at various times, on several different charges.

The pulp, ready for discharging, carries about 50% of moisture, the contained solution averaging 0.07% of KCN and having an average value of approximately $0.40 gold and 1.50 ounce of silver per ton. These values are, of course, higher than would be expected theoretically to remain in the solution after the several decantations and dilutions effected, but, as has already been recorded by several different parties operating similar slime plants, the dissolution of values from the slimes does not cease at the completion of the agitation proper, but continues throughout the washing, and the value of the wash solution is thus being constantly augmented. This feature, however, is more noticeable with the silver than with the gold values, since the gold dissolves much more rapidly than does silver and the maximum extraction of the gold values is obtained earlier. The solution used for washing will always carry a certain quantity of values, which, of course, results in a corresponding, direct increase of the values that would otherwise be carried by the solution contained in the discharged residues. Moreover, it may often be the case that the wash agitations are not perfect. For these reasons the solution contained in the discharged pulp will always carry more values than it should according to calculations based solely upon the successive dilutions and assuming the agitations to be perfect.

(a) This quantity of lime added was in addition to the lime already contained in the solution, sufficient lime usually being present in solution that the addition of 5 c.c. of lime water to a titration (with silver nitrate), for strength of solution, would make no difference in the titration.

(b) See note (a).

(c) Tests No. 5 and No. 6 were on material from near the head of the slimes pits, and which, therefore, contained a larger percentage than usual of fine sands.

Each 2 inches of solution equals 1 ton.

A portion of the sample of the pulp ready for discharging, together with its proper proportion of contained solution, is dried, the assay results being taken to represent the value of the discharged slimes. Another portion of the pulp is washed and then assayed. On an average the washed sample will run about $0.40 of gold and from 1 to 2 ounces of silver per ton lower than the unwashed sample.

As previously noted, the 3-inch centrifugal pumps connected with the decantation vats are the ordinary pumps commonly used for pumping solutions, the only alteration being that the bearing nearest the pump shell is tapped with a 0.25-inch pipe, which supplies the bearing with solution under pressure. These pumps run about four hours in twenty-four, and they have given excellent satisfaction during the five months that the plant has been in operation, the only repair work that has been required on them being an occasional repacking of some of the stuffing boxes.

For experimental purposes, one of the decantation vats has been connected with the pumps in such a manner that by means of loosely threaded elbows the ends of both the suction and discharge pipes are movable, and the suction may be dropped to the point of the conical bottom or may be raised at any

*Trans. Amer. Inst. Min. Engrs.

height up to about 4 feet above it, while the discharge pipe can be raised to the top of the charge or lowered to the bottom. The end of the discharge pipe is curved, conforming to the circumference of the vat, and imparts a circular motion to the charge during agitation. While practically this same idea was tried on the agitation vats, with very poor results, the scheme works very well on the decantation vats, doubtless due to the fact that the slimes before entering these vats have been thoroughly broken up and mixed in the agitation vats. Although the agitation in this specially connected vat seems to be excellent, and to all appearances is better than that taking place in the other decantation vats, no appreciable difference has so far been noticed in the average assays of the discharged residues.

Table IX, giving a somewhat detailed record of the treatment of one charge, may be taken to represent

TABLE IX.—DETAILED RECORD OF SLIMES TREATMENT.

Charge No. 29. Vat No. 1. Net weight of slimes charged, 18 tons. Moisture in slimes as charged, 31 5 per cent. Proportion of solution to slimes present, 2 : 1. 100 lb. lime added at commencement of charging.
Assay value of slimes per ton as charged was $4.34 of gold and 19.52 oz. of silver.

(b) In all these decanted-solution samples, the value of the solution, as added to the charge, has been deducted.

NOTE.—Assay of discharged residues (unwashed): $1.03 of gold, 9.62 oz. of silver. Extraction, 76.27 per cent of gold and 50.47 per cent of silver.
Assay of discharged residues (washed): $0.62 of gold, 8.38 oz. of silver.
Moisture contained in discharged residues, 51.4 per cent. Assay value of solution was $0.40 of gold and 1.24 oz. of silver. Strength, 0.09 per cent of KCN.
Extraction indicated by values contained in decanted solutions: 79.30 per cent of gold and 51.36 per cent of silver.
Total time of treatment: In agitation-vats, 45 hr.; in decantation vat, 48 hr

the usual practice, though the charges then being treated were heavier than those treated at the present time. The usual charge is now but 15 tons of slimes (dry weight), while the proportion, by weight, of solution to slimes present has been increased to 2.5 : 1.

PRECIPITATION.—All solution leaving the decantation vats is passed through the zinc boxes before being reused. The zinc boxes have to be watched very closely, since, owing to the excess of lime usually present in the solution, difficulty is experienced in obtaining good precipitation. Records are kept of the quantity of solution daily passing through the boxes, together with the assay values of the solution, before and after precipitation. These records show that, during the last three months, an average of practically 48 tons of strong and 117 tons of weak solution, or a total of 165 tons, were passed through the boxes daily, the average assays of the solution being approximately as follows:

	Strong Solution.		Weak Solution.	
	Gold.	Silver.	Gold.	Silver.
		Ounces.		Ounces.
Entering zinc boxes	$1.05	2.90	$0.60	1 70
Leaving zinc boxes	0.10	0.40	0.10	0 35

The zinc boxes having a combined total shavings capacity of approximately 120 cubic feet, the rate of flow of solution through the boxes during 1904 averaged 1.37 ton per cubic foot of shavings per twenty-four hours.

The precipitates recovered are always of lower grade than those obtained in the sand plant, because, in spite of all precautions, a certain quantity of suspended slimes will be carried with the solution into the zinc boxes and will be retained there, thus lowering the grade of the precipitates. The highest grade precipitates yet recovered from the slimes plant assayed approximately $6800 of gold and 17,300 ounces of silver per ton.

TONNAGE, PERCENTAGES, ETC.—The normal capacity of the plant, while treating 15-ton charges and allowing a two days' treatment in both agitation and decantation vats, is 30 tons per day. During the last quarter of 1904 approximately 2550 tons of slimes (net dry weight) were treated, and the extraction during this period, shown by the differences between assays of the charge and the residues, was 74.9% of the gold and 49.2% of the silver. During this period the assay values of the slimes, as charged, averaged approximately $4.35 of gold and 19.25 ounces of silver per ton. Since the above was written the consumption of cyanide has been steadily decreased, and during the last two months (March and April, 1905) has averaged 3.56 pounds of sodium cyanide (equivalent to 4.40 pounds of potassium cyanide) per ton of slimes treated.

The average extraction of silver for the last three months has been 51%.

The consumption of cyanide, zinc and lime per ton of dried slimes treated during this time was: Sodium cyanide 4.42 pounds, zinc 0.957 pound, lime 13.95 pounds. The sodium cyanide consumption is equivalent to 5.52 pounds of potassium cyanide. Table X gives the operating cost per ton of slimes treated:

TABLE X.—WORKING COSTS PER TON OF SLIMES TREATED.

Cyanide (4.42 pounds at $0.63)	$2.785
Zinc (0.957 pound at $0.30)	0.287
Lime (13.95 pounds at $0.0118)	0 165
Other supplies	0 238
Lubricating	0.033
Labor	0.491
Salaries	0.748
Assay office (labor and supplies)	0.066
Power (ditch, maintenance and supplies)	0.621
Miscellaneous (lighting, etc.)	0.002
Management and general expenses	0.179
Total	$5.615

NOTE.—In Mexican currency during this period $5.615 was equivalent to $2.66 gold. The cos of realizing on the precipitates produced is not included in the above working costs. For the same reasons as given in the portion of this paper relating to the sand treatment, these expenses are unusually high. The average cost of realization on the precipitates produced in the slimes plant, per ton of dry slimes treated, is: Government taxes, $0.856; treatment charges (including transportation expenses), $1.202; total, $2.058.

I wish to acknowledge my indebtedness to Mr. W. T. MacDonald, mill superintendent of the Palmarejo & Mexican Gold Fields, Ltd., for his valuable assistance n the preparation of this paper.

New Methods in Treatment of Low-Grade Copper Ores.*

Written by N. S. KEITH.

The following described process of treating low-grade copper ores, written with particular reference to the ores occurring in certain geological horizons in the Eastern United States, are of interest, as it deals with a problem which is not uncommon in some western localities as well, particularly in Utah, Arizona, western Colorado and southern Nevada, and the ideas are suggestive, at least, of application in many districts where ores of the character here described are found.—ED.

In many sections of the United States there are vast deposits of sandstone, carboniferous, triassic, and earlier, which contain copper, either in the metallic state, or mineralized as sulphides and carbonates. The chief sulphide is Cu_2S, variously called chalcocite, copper glance, or cuprous sulphide. Sometimes chalcopyrite occurs, more or less mixed or combined with iron pyrites, but comparatively infrequently. In the eastern section of the country these cupriferous rocks are noticeably occurrent in the Appalachian ranges, from Maine and Vermont to the Carolinas.

In the sandstone regions, disconnected from the main range, such deposits have been found, and have been somewhat exploited from the earliest years of the history of the country.

Beyond Maine, along the coast of New Brunswick, there is a considerable tract of cupriferous, carboniferous sandstone at Dorchester. In Connecticut, not far from New Haven, are copper-bearing sandstones. In New Jersey, at Arlington, 8 miles west of New York City, are such sandstones of the triassic formation, with intrusive trap dikes and sheets, from which trap the copper impregnations were probably derived.

On the banks of the Delaware river, in Warren county, New Jersey, a few miles above the Delaware water gap, are cupriferous rocks, classed as Medina and Oneida sandstones, of an older period than the triassic, and not associated with trap rocks, or other evidences of volcanic disturbances. There are other places in New Jersey where sandstone deposits have had attention given them.

In Adams county, Penn., nor far from Gettysburg, there are sandstones which contain not only chalcocite and carbonates, but metallic copper. In this case, as in all of the others, the copper carbonates (malachite and azurite) occur at and near the surface, and are the result of the action of the atmosphere and carbonated waters on the chalcocite and metallic copper.

All of these sandstones are essentially siliceous, being built up from quartz grains cemented together by silica from thermal waters containing silica in solution. The silica solution may have been, and probably was, the result of the solvent action of the thermal waters on the sand itself while lying on a horizontal plane, from which position the sandstones have been moved to planes having various dips from their original ones.

The sandstones frequently contain a small percentage of calcium carbonate, or calcium in some other combination, such as the sulphate.

In Virginia, near Virgilina, on the boundary line of North Carolina, there is a mineralized belt of country extending 25 miles north and south in the two States. The country rock is slate; in this slate there are quartz veins and porphyry dikes, parallel with each other, and conformable with the stratification of the slate.

These veins and dikes carry carbonates of copper and chalcocite, with bornite, and occasionally chalcopyrite. These rocks are siliceous, as in the other cases.

Besides their contents of copper the rocks at the various points I have named carry gold and silver, in amounts varying from traces to some dollars in value per ton of rock. The copper constituent averages in the several cases at from 1% to 3% of the weight of the rock; that is, from twenty to sixty pounds per ton.

There are many other places at which like rocks are obtainable; but these serve to illustrate prevailing conditions, and to show the foundation for the methods of treatment which I am about to consider.

In all of these cases the smelting of the rocks to obtain their metals is possible in theory, and practicable under favorable conditions; but these favorable conditions are absent. The unfavorable conditions are:

1. The absence of, or expense of, suitable fuel at the mines.

2. The absence of, or the expense of, suitable fluxes, such as iron oxides, iron sulphides, or limestone, at the mines.

3. The cost of transporting the rock to the neighborhood of fuel and fluxes.

4. The "low grade" of the rock. That is to say, the copper, gold and silver are not in quantities enough to yield values sufficient to pay either for

*Journal Franklin Inst.

bringing the fuel and fluxes to the mine, nor for taking the rock to the fuel and fluxes.

There are places where copper ores and rocks of no higher grade than these are worked at a profit. But they are where the ores are "self-fluxing." That is to say, where the ore itself is composed of materials which naturally react on each other in the furnace to produce slags which are liquid enough to permit the metals to come together, and where the necessary fuel is cheap enough; or, in cases where there are cheaply obtainable suitable ores to admix so as to make a fusible mixture. Then, again, the rocks which have their copper in the metallic state can be worked after the methods pursued at the Lake Superior mines, where rock containing less than fifteen pounds of copper per ton are mined and reduced at a profit.

But I am to consider the treatment of siliceous rocks where the considerations are unfavorable for smelting.

Foremost among the methods which have been tried is that of "leaching." Leaching consists in submitting the cupriferous material to the action of solvents of the copper constituent, and then reducing the dissolved copper from the solution by means of a reducing agent. The rock must first be crushed and ground to a fineness, say that of fine sand, so that the solvent may have access to all of the copper mineral. About the only available solvent of the chalcocite and metallic copper is a solution of ferric sulphate or ferric chloride. A solution of either of these salts of iron dissolves, though slowly, both chalcocite and metallic copper, by forming copper sulphate or copper chloride, and the ferric solutions are changed to ferrous solutions. These ferrous solutions are changed by exposure to air, by absorption of oxygen, to the ferric state; and are then again usable to dissolve more copper. The copper may then be deposited from its solutions by means of metallic iron, generally scrap, or by means of electricity.

This seems at first glance a simple process. But there are serious complications, chief among which is the presence of lime, or calcium compounds, in the rocks, as is almost always the case.

The lime acts up to its limit in quantity to neutralize its combining equivalent of the sulphuric acid, or chlorine, constituent of the solvent, and that action is preferential above that on the copper. The only exception to this is when the lime is present as a sulphate, which is seldom. It is generally calcium carbonate.

The next leaching method is to grind the rock to sand, as before, and then roast it, so as to oxidize its oxidizable constituents. The result then is, if the operation is carefully performed, the formation of oxide of copper in the sand, and of some calcium sulphate, and some calcium oxide, or lime. Then the roasted sand is leached with a dilute solution of either sulphuric or hydrochloric acid. But this has been found impracticable where acids are expensive, and where there is lime in quantity as low, even, as one-half of 1% of the rock.

If there be at hand some sulphide ores, as of iron, carrying some copper, say 2% of the latter, it may be ground and mixed with the ground sandstone or quartz and roasted as before. Then the lime will be sulphated and will not thereafter combine with the acid to its loss in the subsequent leaching.

Having thus obtained the solution of copper, with questionable economy, the method of precipitating the copper therefrom by the use of iron scrap, or pig, is pursued in various localities. This method of precipitation of copper is very old and well known, and is only one of the steps constituting some of the modern methods pursued in obtaining that metal. But, to-day, that step is too costly in most localities. While, theoretically, fifty-six pounds of iron should precipitate 63.35 pounds of copper, in practice nearly three times that quantity of iron is used. This comes from excess of acid in the copper solution, a waste in itself, uniting with its equivalent of iron; from oxidation of iron; from the formation of ferrous salts; scale and rust and dirt on the iron as purchased, small pieces undissolved, etc. Then the precipitated copper is very impure. It contains on the average about 70% of copper. The other constituents of this "cement copper," so-called, is iron oxide, sand, and other extraneous matter, which must be removed by smelting.

A better method is this: Having obtained the solution of copper by some method, it is deposited by means of electricity. In brief, this is accomplished by immersing the electrodes of a source of electricity into the copper solution, and causing a graded current of electricity to flow from the anode through the solution to the cathode. In this way, if the strength of the electric current be properly proportioned to the amount of copper in the solution (the electrolyte) at all instants of the time of the operation there will be produced on the cathode a deposit of reguline copper of great purity, and in a commercial scale much cheaper than by iron as above outlined.

But the anode must be insoluble. In sulphate solutions lead stands the action in the bath much better than any other sufficiently cheap material. Carbon anodes do not endure in sulphate solutions, but are practicable in use in chloride solutions, in which lead anodes are quickly chloridized. But lead anodes must be, as far as possible, kept continually in action to prevent them from sulphating. The cathode is generally a thin sheet of copper at the start, prepared by the electro-deposition of copper on a cathode of lead, from which latter it is stripped when thick enough for use.

Under the just-described method it is necessary, in order to economically deposit the ultimate quantity of reguline copper within a required time, to begin the deposition by use of the current at its maximum density between the electrodes, permissible in the production of reguline metal on the cathode, and retrogressively decrease that density as the action goes on, and in proportion to the decrease of the metal in the solution, till, at the end the minimum density of current is in use, and the minimum amount of copper is left undeposited in the solution.

It is not necessary to deposit all of the copper, because the solution will be used again to dissolve more copper, the acid from the deposited copper being freed by the electrolytic action so that it may again combine to form a soluble salt of copper.

It is evident from the above that the source of electricity, a dynamo, is not acting during the time on the average above one-half of its capacity. It was started at its maximum and finished at its minimum.

To obviate this difficulty I have devised the following described apparatus and method: The deposition vats are placed in series, so that the liquid or solution is caused to flow from the first to the last in regular succession. They are also connected with the dynamos in electrical series, so that the electric current flows through all in equal strength in amperes.

As the solution has, in practice, a nearly uniform amount of copper per unit in it as it flows into the first vat of the series, that vat has in it a cathode surface which permits the deposition of about the maximum amount of reguline copper obtainable on that area of surface.

That area is limited by the amperes of current available. In other words, the density of current is such that reguline copper is deposited, but the density of current is less than that which causes the deposition of a brown, sandy deposit.

In the second vat is a larger cathode area. As the same amperes of current flow in this vat, the density of current is less—because the area of cathode is greater. The same amount of reguline copper is deposited as in the first vat, and in the same time, but over a larger area.

The same progressive increase in cathode area is made in each successive vat of the series. The same current flows through all, but its density is less and less through the several vats of the series, so that reguline copper is deposited to the same amount in each, until the depleted solution flows out of the last vat of the series, to be again used to dissolve copper from more rock or ore. In this way the electricity is used most economically.

But none of these leaching methods obtains the gold and silver which almost invariably accompany the copper. To obtain these, leaching by cyanide of potassium solutions might be performed after thoroughly washing the pulp which has been treated for copper. But this will often be found too expensive for the values obtainable.

I have devised and put into successful operation the following described method of treating the siliceous copper-bearing rocks which we have been considering. It is based on these chemical and metallurgical facts:

Silica alone is infusible at temperatures at which copper, gold and silver are melted. In those rocks there is not enough iron or lime to act as fluxes for the silica, which last averages 90% or more of the whole.

Oxide of iron, and oxide of calcium, separately, are likewise infusible.

Copper carbonates, azurite and malachite, when exposed to red heat, are decomposed; carbon oxide is freed as a gas, and cupric oxide remains. If the atmosphere in which this decomposition takes place be a reducing one, say carbon monoxide, then the copper is reduced to the metallic condition by passing of the oxygen of the cupric oxide to the carbon monoxide to produce carbon dioxide. If the temperature be high enough to melt copper that will be found in small metallic globules if the carbonates were diffused in the rock.

Chalcocite, or copper glance, Cu_2S, when exposed to a like heat in an oxidizing atmosphere, as on the hearth of a roasting furnace, is decomposed; the sulphur partly distills off, and is partly oxidized to sulphurous acid, SO_2. The copper is first freed as a metal, and then rapidly oxidized to cupric oxide. If, then, the character of the flame and gases be changed to a reducing nature the copper oxide will be reduced and fused as stated above.

If carbon, such as coal, be ground or pulverized, and be projected into a flame in a furnace with free access of air, it immediately ignites and is oxidized to carbon monoxide and carbon dioxide. If the air be insufficient to furnish oxygen enough for the formation of dioxide only monoxide will be formed.

The air admitted with the powdered carbon may be sufficient to form at the first stage of the combustion only carbon dioxide, but as the action continues, the hot particles of carbon absorb half of the oxygen of the dioxide, reducing the latter to monoxide.

The atmosphere resulting from this operation consists of nitrogen, from the air, and carbon monoxide from the union of the oxygen of the air with the carbon. There are, also, small quantities of gaseous hydro-carbons, because of reactions due to the presence of water in the air and in the coal. This atmosphere of hot gases is ready to, and does, take oxygen from hot oxides and thus reduces them to the metallic state.

The practical, working furnace in which the several reactions above recited take place consists of a vertical shaft about 20 feet high, constructed of red brick with a fire-brick lining.

At the top of this shaft are many holes, or openings, through which the powdered rock, powdered coal and flames from producer gas, or like fuel, are introduced. The bottom of the interior of the shaft is inclined at an angle of about 45°, and this incline is extended into a dust-collecting chamber. This chamber, in turn, connects with another vertical shaft, also with an inclined bottom, dipping toward the other incline. The interior of this shaft is filled with pieces of coke, or small stones. This latter shaft is called the "condensing chamber." Near its top is a sprinkler to distribute water over the coke or stones, after the manner of a gas washer or scrubber. The draft for this furnace is produced by an exhaust fan through a pipe from the top of the condensing chamber. The draft is downward in the first shaft and upwards in the condensing chamber.

The operation by which copper, gold and silver are extracted from the siliceous rocks is described as follows:

The rock, as it comes from the mine, is dumped from the cars into a crusher, or a series of crushers, which reduces it to sizes suitable for the pulverizers, into which it is automatically fed, and in them reduced to powder. The fineness of this powder is determined by the diffusion of the copper mineral in the rock; and it should be so fine that the particles of rock and mineral are no longer coherent, but, of course, still mixed. The degree of comminution is measured by sieves, which may be as fine as 60-mesh, or finer, or coarser, according to the above requirement.

At some stage of this process of comminution finely pulverized coal, in weight about 3% of the rock, is intimately mixed with the powdered rock, and the mixture is deposited in a hopper above the furnace shaft.

The draft and gas flames having been started, the comminuted mixture of rock and carbon is continuously fed into the holes at the top of the shaft, passing into the furnace with the flames and air. The particles of carbon and copper mineral are immediately ignited and oxidized by the oxygen of the air in which the particles are suspended and diffused.

This oxidation is combustion, and produces an intense heat. At first the carbon particles have their surfaces oxidized to produce carbon dioxide; but as the particles pass farther down the shaft the oxygen of the air supply becomes exhausted, and then the carbon dioxide parts with half of its oxygen to the unburned incandescent carbon to form carbon monoxide, which last, in its turn, acts upon the oxides of copper and silver, taking their oxygen, thus reducing them to the metallic state.

As the heat is intense, these particles of metal are melted and assume globular shape.

The gold particles are likewise fused. The heat does not fuse the silica nor the lime. The result of this operation is a sand carrying in it minute globular particles of copper, gold and silver.

The dust and condensible gases are collected on the wetted surfaces of coke or stones in the condensing chamber and washed by the water to the bottom, where the water also meets the sand and carries it out of the furnace, in a constant stream upon concentrators, which separate the sand from the metal particles.

The metallic concentrates are then dried, melted and cast into merchantable shapes; such as copper anodes, when there is enough gold and silver to pay for the expense of electrolytic refining and separation of the associated metals.

The process is a continuous one and automatic from start to finish. It is cheap; and under the economic conditions of the localities we have considered the cost does not exceed $1 per ton on a scale of treatment of 100 to 200 tons per day of 24 hours.

The gas drawn from the furnace by the exhaust fan is a combustible one, consisting mainly of carbon monoxide and nitrogen, and may be used for heating purposes. The sulphur dioxide and carbon bisulphide, if any of the latter, are condensed in the chamber and pass off in the water.

The limits of this paper do not admit of entering into specific details of construction and operation.

The process is applicable in many cases where older methods are not practicable.

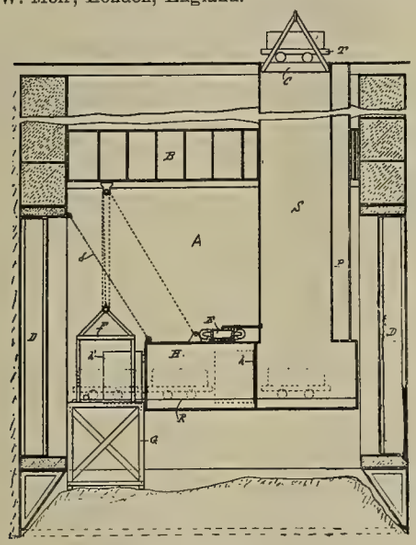
To attempt to locate and run long and expensive tunnels through bedrock to reach gravel channels, the depth of which has not been previously ascertained by means of drilling numerous bore holes, is foolhardy. Many tunnels have thus been run by guess, but those engineered in this haphazard manner usually fail in accomplishing the desired result — the tapping and draining of the channel.

Mining and Metallurgical Patents.

PATENTS ISSUED AUGUST 22, 1905.

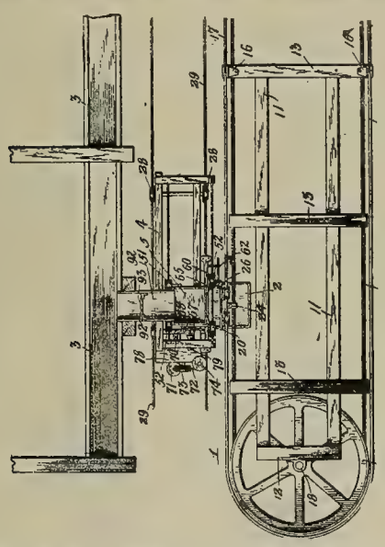
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

AIR LOCK APPARATUS FOR CAISSONS.—No. 797,817; E. W. Moir, London, England.



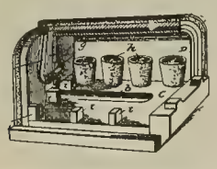
Air lock apparatus, comprising caisson having air-tight floor, vertical shaft, hoisting cage therein, horizontal air lock at its lower end, with runway in air lock and secondary hoist within caisson.

AUTOMATIC BUCKET LOADER FOR AERIAL TRAMWAYS.—No. 797,944; E. F. Crawford, Nelson, Canada.



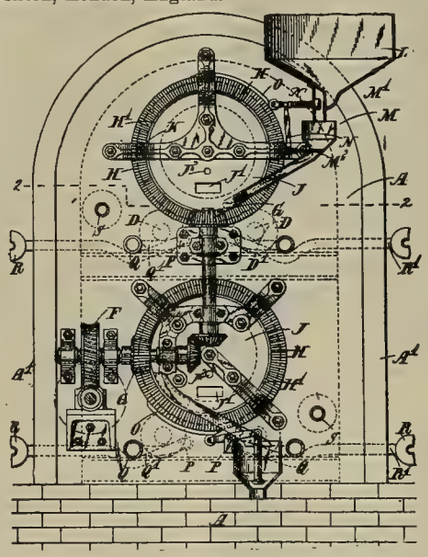
Combination of bucket or other container of tramway, loading hopper mounted to reciprocate and provided with discharge gate, accelerating lever for imparting motion of bucket to gate to open same, accelerating lever for imparting motion of gate to hopper to cause latter to move along with bucket while it is being loaded from hopper, means for automatically releasing hopper from bucket, and means for automatically closing gate and returning hopper to normal position.

ASSAY FURNACE.—No. 797,901; A. M. MacDuffee, Chloride, Ariz.



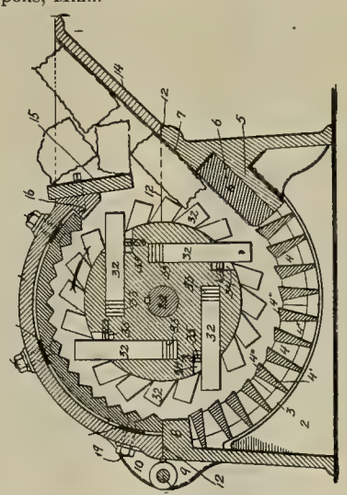
Assay furnace comprising base and ends and body portion forming muffle chamber, one of ends having projection on its inner face inclosing air space, muffle in chamber having opening in back end to connect air space with interior of muffle, muffle having normally loose, readily separable bottom thereby adapting muffle for both melting and cupeling operations, means for admitting flame to muffle, and means whereby spent products are allowed to escape from furnace.

FURNACE FOR ROASTING ORES.—No. 797,915; W. T. Rushton, London, England.



In continuous roasting furnace, combination of refractory furnace chamber, rotatable cylindrical muffle mounted therein having internal spiral conveying flange, inclined baffles projecting laterally therefrom, inwardly directed flange fixed on each end of cylinder forming annular recess, stationary disks closing cylinder ends and resting in annular recesses and means for rotating cylinders.

ROTARY BREAKER.—No. 797,616; J. M. Schutz, Minneapolis, Minn.

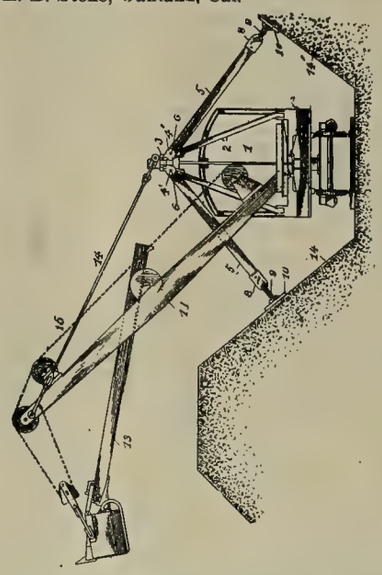


Rotary breaker comprising horizontal cylindrical shell or casing having feed chute in side and provided with breaker block at foot of chute, in combination with curved grating extending from block across bottom of casing, corrugated lining provided in top of casing, shaft extending through casing, bearings therefor, roll mounted on shaft within casing, and flat faced or ended hammer bars tangentially fixed in roll and therewith nearly filling casing.

CORE DRILL.—No. 797,627; W. S. Smith, Bigrun, Pa.

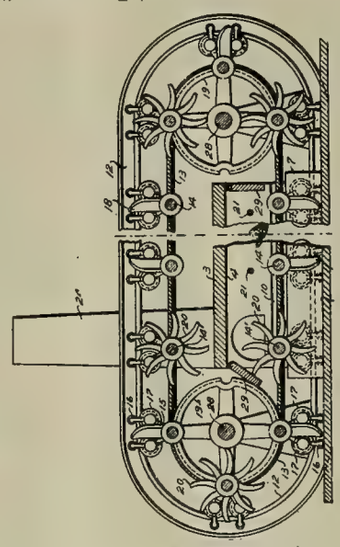
Combination with reciprocatory frame, of pair of racks carried by frame and adjustable thereon to operative and inoperative positions, teeth of racks being yieldable in opposite directions, respectively, shaft, and gear carried by shaft and intermeshing with racks.

JACK ARM FOR EXCAVATING MACHINES.—No. 797,627; E. B. Stone, Oakland, Cal.



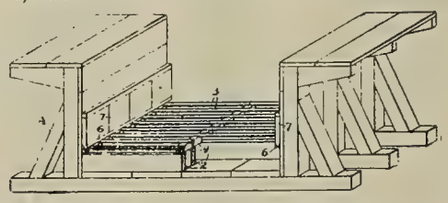
In machine of character described, combination with A-shaped supporting standard of pair of jack arms hinged to apex portion of standard so as to swing in vertical plane.

ORE ROASTING FURNACE.—No. 797,584; C. E. Keating, East Chicago, Ind.



In device of class described, combination of horizontally disposed hearth for supporting layer of material to be roasted, track extending along each side of hearth, shaft extending across hearth and supported by wheels riding on tracks, plurality of stirring devices mounted on shaft and rotatable about axis thereof, stirring devices having radially disposed arms and being adapted to rotate through engagement with material on hearth for stirring same, arms being curved in radial direction whereby rotation of stirring devices when shaft is moved along hearth will cause arms to pass endwise into mass of material on hearth and be lifted edgewise therefrom, and means for moving shaft along hearth.

MINING SLUICE.—No. 797,168; P. Bouery, Weaverville, Cal.



In sluice having bottom and sides and obstructing riffles, T rails having base flanges fixed upon riffles, blocks interposed between rails having ends fitting curvature of rail sides, holes made through blocks and countersunk depressions at ends, bolts extending through holes and through rail flanges, heads of bolts being enclosed within depressions at one end of block, and nuts by which bolts are secured to rail web being enclosed in next adjacent block.

Notes on Copper Deposits Near Tokar, Sudan.*

Written for the MINING AND SCIENTIFIC PRESS by W. H. SHOCKLEY.

These copper deposits lie between 17° 30′ and 18° north and 37° 45′ to 38° 30′ east. They cover with their float an area of 500 square miles; the ore in place was found over an area of 130 square miles. They have been but little studied and nothing has been published on them that I know of. The only engineers who have visited the region are J. F. Morris and myself; we were there during February to April, 1905.

The region is mountainous, the highest summits rising to 9121 feet on the Erythrean border, at a distance of 50 miles from the sea.

The formation is exclusively made up of schists having a strike a little east of north and a steep westerly dip as a rule. The schists are varied in structure and injected into them are eruptive rocks with well marked crystals. Limestones, sandstone, basalts, porphyries and granites, all of which are found to the west, are wanting.

The slopes facing the sea are covered with dense brush and small trees, and on the higher ranges are forests of juniper. The country is sparsely peopled by Hasas, a tribe of black Arabs, living almost entirely on milk from their sheep and goats. Cattle and camels are also kept. There is much game, gazelle, koodoo, warthogs, bustard and guinea fowl being the principal varieties.

The copper float found consisted of rock, stained green by malachite, varying from small pebbles to boulders weighing twenty-five pounds. The float, though distributed over 500 square miles, is nowhere abundant, and it needs careful searching to find it. The Arabs soon become expert in finding float; at first they had great difficulty in distinguishing between the chlorite and epidote rocks, which are common, and the copper ore. Specular iron ore is found as float and also in lodes. This mineral is found in the croppings of the copper veins at Bearhaven, in Ireland, which consist chiefly of white quartz. After sinking a short distance the quartz is replaced by copper ores. This fact I learned from Mr. Morris, who examined these mines recently with a view to reopening them.

By following up the copper float we found a number of lodes and indications of many others which our limited time did not allow us to discover. None of these deposits showed any ore that would pay to ship. It is possible that some of the deposits we found may improve in depth, and further prospecting may find much better lodes than we have yet seen.

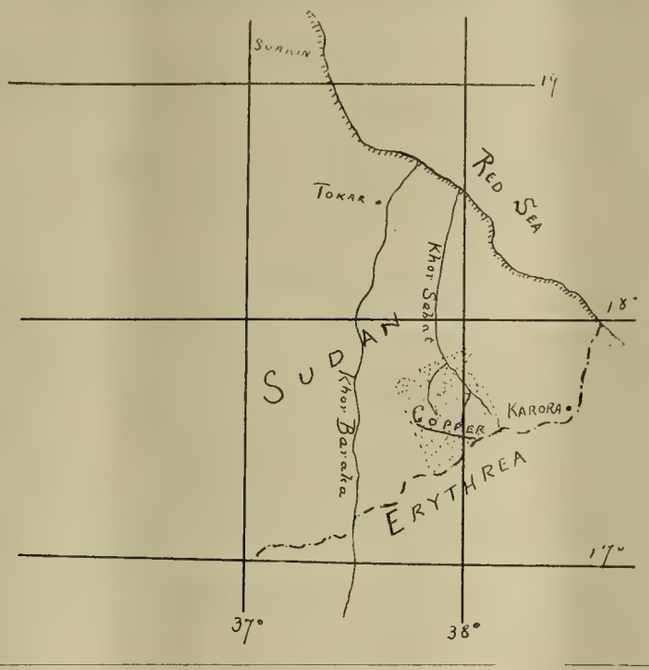
The strongest outcrop we saw was of white quartz 75 feet long, 10 feet high and 15 feet thick. This showed many small stains of malachite. Strata of schist, impregnated with copper, were found in many places varying from lenses 40 feet long, with a width of a few inches to 4 feet, to a vein a foot wide and extending for several hundred feet along the surface. The largest deposit showed copper stains in a space 100 feet wide by 200 feet long. The staining did not cover the whole space; the largest outcrop here was 15 feet long by 6 feet high and 2 feet wide. A sample taken here gave 2% copper.

*See illustrations front page.

The following assays were made chiefly of float and are only valuable as showing the existence of good ore:

From—	Copper Per Cent.	Silver Ozs.	Per Ton. Dwt.	Grs.
Khor Arelrib	2.01	0	6	14
Ibrahim Ledge, near Hubrab	2 03		traces	
Abandob (float)	11 96	2	2	11
Khor Dareb	42 59	20	16	0
Khor Arelrib at Abandob (float)	21 25	7	2	17
Khor Arelrib, near Abandob (float)	14 33	2	19	0
Khor Hamrik (float)	nil		nil	
Near Kutal Dul	34.24	15	10	0
Small Khor from Arelrib, near Abandob	5 59		traces	
Mahomed Ledge, Khor Hamrik	2 92		traces	

All these deposits are on the concession of the Tokar Syndicate, and will be further studied the coming winter. No other mineral deposits were found. Quartz veins are very abundant in one portion of the concession, and the ground is covered to a depth of several inches for many square miles with quartz float, but all the samples assayed were barren.



Sketch Showing Position of Copper Deposits Near Tokar, Sudan.

The Ventilation of Mines.

NUMBER IV.

Appliances for Regulating Air Currents: The use of doors and stoppings for systematizing the ventilation of metalliferous mines has not had the attention which its importance deserves, the currents being generally allowed to travel haphazard through the mines. The smoke and vitiated air from lower workings are consequently often found passing into upper ones to the detriment of the men there, when by a little trouble they could be diverted into a return way in which they could do no harm. Each level should, as far as possible, be made a separate "split" from the downcast current, the air being guided through the stopes above it and thence into the main return. Frequently it is not practicable to make each level a separate split, and then two or more may have to be worked on one split, but the more the principle of ventilating the mine in sections can be carried out the more thoroughly it will be ventilated.

The regulation of the distribution of the air can be carried out by stopping all unnecessary air ways, and placing doors so as to direct the currents into the paths along which they are desired to travel. In our examination of the metalliferous mines we found only two which made regular use of an air door system throughout the mine, namely, the Sons of Gwalia and the Ivanhoe, and in both the evidence of witnesses showed that their construction had been attended with great improvement of the ventilation. In the Sons of Gwalia the main shaft is an upcast, the downcast air coming from the surface into the mine through winzes and stoped-out ground, and in order to drive it to the bottom levels it proved absolutely necessary to use doors to prevent it returning to the upcast by the shortest route. In the Ivanhoe case the object of the air doors is to carry the downcast air through the main shaft into the bottom of the mine before allowing it to escape upwards through the workings. In the Lake View Consols mine good use is made of air doors at one or two important points, and in the Ida H. mine, near Laverton, we noticed a well-considered plan of using bag doors to good advantage, but in the great majority of the mines visited there was very little attempt made at any regulation of the air currents. Undoubtedly the judicious use of doors and stoppings would be of the very greatest advantage in almost all mines. In our opinion it should be incumbent on every mine to show should be marked, in order that consideration of this the course of its ventilating currents on suitable plans and sections, on which also all doors and stoppings question should be constantly forced upon the attention of the management, and come prominently under the notice of the inspectors of mines.

Devices for Mechanical Ventilation: A great many different devices for mechanically assisting the ventilation of metalliferous mines were mentioned by witnesses as being used in mines with which they were familiar here and elsewhere, from the large ventilating fans used in collieries to hand-driven fans, water jets, and other simple appliances employed in ventilating small portions of mine workings. There can be no doubt that, in order to insure a thorough and constant ventilation throughout a mine, the use of a powerful fan is the most certain method of attaining the desired end, and that in very many cases where the natural ventilation presents difficulties, the best solution would be a fan installation. The case of the Sons of Gwalia mine seemed to us one which could best be dealt with by a fan. Instead of having the main shaft the upcast, it would be much preferable to have it the downcast into the mine, which could be brought about by putting an exhaust fan on the small shaft, which is the present principal in-take of air, and enlarging the air-way from this through the workings. So long, however, as a fair amount of natural ventilation can be obtained in metalliferous mines in the course of opening them up in the ordinary way, it is hard to persuade owners to go to the expense of installing mechanical ventilation on a large scale, even though in many cases such ventilation would be so much superior that economy, instead of expense, would result. It is somewhat difficult to convince managers that this might be possible without direct comparison of cases where one system has been tried against the other, which are not available in this State; but the experience of coal mines strongly supports the contention that mechanical may be even more economical than natural ventilation, notwithstanding the obvious expense of the former as shown on the cost sheet. Should it enable the working force underground to do only 1% more work in the same time, there would evidently be a very considerable credit to put against the debited cost. That the state of the ventilation does affect the working efficiency of the men employed can not be disputed, especially when the mines are hot. With better ventilation, not only is it possible for men to work longer, on account of more rapid clearing of the smoke from blasting, but the lowering of the temperature brought about also enables them to exert themselves to better effect and do more work. The observations of Dr. Haldane as to the effect on men of high temperatures underground show very strikingly the impossibility of performing vigorous exertion when the workings are very hot and moist. That the temperature may be greatly reduced by ventilation was proved in the driving of the St. Gothard tunnel, where, "before the fan was brought into operation, the temperature used sometimes to be as high as 107° F., with 97% of moisture; but by artificial ventilation the temperature fell to 81° F., subsequently to 74.5° F."

Any of the well-known types of fans used for colliery ventilation may be used also for metalliferous mines, either driving air into the workings (plenum system) or exhausting it out of them (vacuum system), and the choice is a matter for individual consideration.

In the system of ventilating mines by large fans at surface, either blowing or suction, the mine excavations themselves are the principal conduits for the air. Another system, however, is often applied, especially in conjunction with natural ventilation, namely, that of blowing or exhausting the air through pipes. Root's and similar blowers are often used for this purpose, driving or drawing air through pipes into or from the places where ventilation is required. In the blowing system the pure air is confined to the pipes until it reaches the points of discharge, and all the smoke and vitiated air have to travel back through the mine passages; while in the exhaust system the pure air travels inwards to the faces through the workings, and the fumes are removed in the pipes and do not pass over the workmen to any extent. When the air is blown in, however, there is an advantage in the fact that the current can be sent forward some considerable distance from the end of the pipe, while with an exhaust there is little current perceptible a few feet from its end. The blast is, therefore, much preferable in clearing ends of smoke, as it is impossible to keep pipes right up to the faces.

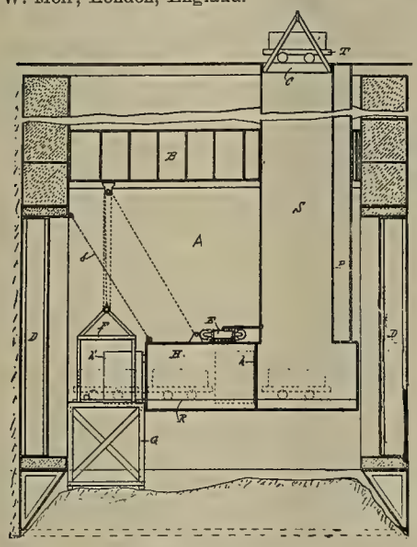
Although the main ventilation of a mine may be very good, it generally happens that development work must be carried on so far ahead of any possible connections that some means must be adopted of carrying a current of air into them. This can occasionally be done by bratticing or by the air-sollar system, as already mentioned; but usually pipes of some sort are the most applicable method. Very generally, however, those used are much too small. Small fans and blowers driven by hand, or by water power, if available, or by a small compressed air engine, or by an electric motor, are often used successfully in such cases, causing air to pass in from a well ventilated part of the mine and removing the vitiated

Mining and Metallurgical Patents.

PATENTS ISSUED AUGUST 22, 1905.

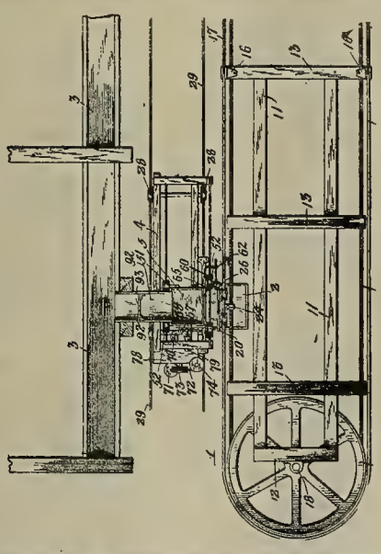
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

AIR LOCK APPARATUS FOR CAISSONS.—No. 797,817; E. W. Moir, London, England.



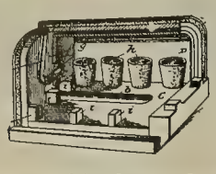
Air lock apparatus, comprising caisson having air-tight floor, vertical shaft, hoisting cage therein, horizontal air lock at its lower end, with runway in air lock and secondary hoist within caisson.

AUTOMATIC BUCKET LOADER FOR AERIAL TRAMWAYS.—No. 797,944; E. F. Crawford, Nelson, Canada.



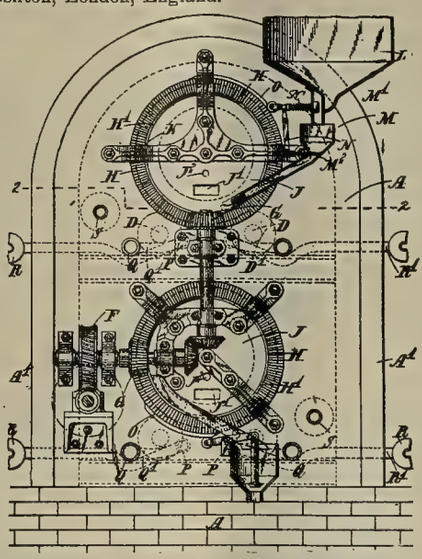
Combination of bucket or other container of tramway, loading hopper mounted to reciprocate and provided with discharge gate, accelerating lever for imparting motion of bucket to gate to open same, accelerating lever for imparting motion of gate to hopper to cause latter to move along with bucket while it is being loaded from hopper, means for automatically releasing hopper from bucket, and means for automatically closing gate and returning hopper to normal position.

ASSAY FURNACE.—No. 797,901; A. M. MacDuffee, Chloride, Ariz.



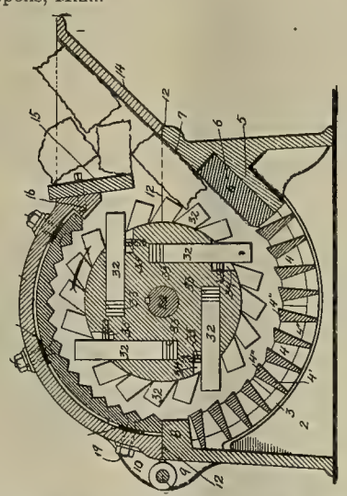
Assay furnace comprising base and ends and body portion forming muffle chamber, one of ends having projection on its inner face inclosing air space, muffle in chamber having opening in back end to connect air space with interior of muffle, muffle having normally loose, readily separable bottom thereby adapting muffle for both melting and cupeling operations, means for admitting flame to muffle, and means whereby spent products are allowed to escape from furnace.

FURNACE FOR ROASTING ORES.—No. 797,915; W. T. Rushton, London, England.



In continuous roasting furnace, combination of refractory furnace chamber, rotatable cylindrical muffle mounted therein having internal spiral conveying flange, inclined baffles projecting laterally therefrom, inwardly directed flange fixed on each end of cylinder forming annular recess, stationary disks closing cylinder ends and resting in annular recesses and means for rotating cylinders.

ROTARY BREAKER.—No. 797,616; J. M. Schutz, Minneapolis, Minn.

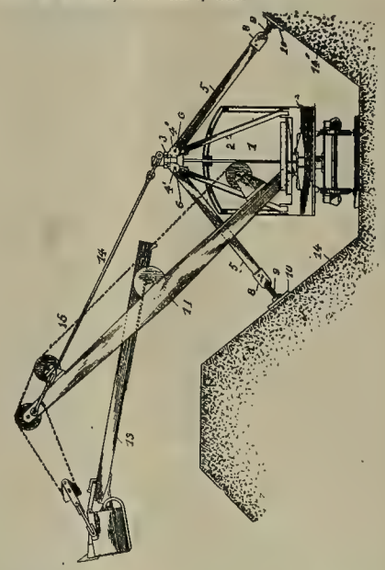


Rotary breaker comprising horizontal cylindrical shell or casing having feed chute in side and provided with breaker block at foot of chute, in combination with curved grating extending from block across bottom of casing, corrugated lining provided in top of casing, shaft extending through casing, bearings therefor, roll mounted on shaft within casing, and flat faced or ended hammer bars tangentially fixed in roll and therewith nearly filling casing.

CORE DRILL.—No. 797,627; W. S. Smith, Big-run, Pa.

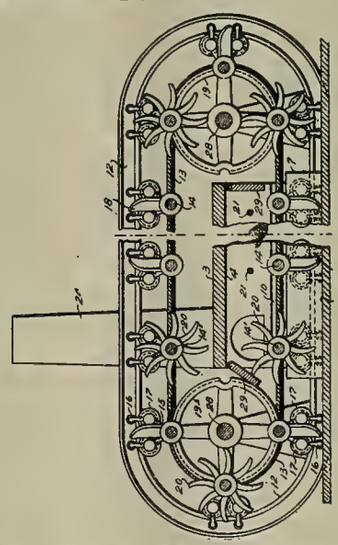
Combination with reciprocatory frame, of pair of racks carried by frame and adjustable thereon to operative and inoperative positions, teeth of racks being yieldable in opposite directions, respectively, shaft, and gear carried by shaft and intermeshing with racks.

JACK ARM FOR EXCAVATING MACHINES.—No. 797,627; E. B. Stone, Oakland, Cal.



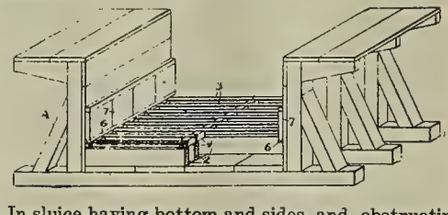
In machine of character described, combination with A-shaped supporting standard of pair of jack arms hinged to apex portion of standard so as to swing in vertical plane.

ORE ROASTING FURNACE.—No. 797,584; C. E. Keating, East Chicago, Ind.



In device of class described, combination of horizontally disposed hearth for supporting layer of material to be roasted, track extending along each side of hearth, shaft extending across hearth and supported by wheels riding on tracks, plurality of stirring devices mounted on shaft and rotatable about axis thereof, stirring devices having radially disposed arms and being adapted to rotate through engagement with material on hearth for stirring same, arms being curved in radial direction whereby rotation of stirring devices when shaft is moved along hearth will cause arms to pass endwise into mass of material on hearth and be lifted edgewise therefrom, and means for moving shaft along hearth.

MINING SLUICE.—No. 797,168; P. Bouery, Weaverville, Cal.



In sluice having bottom and sides and obstructing riffles, T rails having base flanges fixed upon riffles, blocks interposed between rails having ends fitting curvature of rail sides, holes made through blocks and countersunk depressions at ends, bolts extending through holes and through rail flanges, heads of bolts being enclosed within depressions at one end of block, and nuts by which bolts are secured to rail web being enclosed in next adjacent block.

Notes on Copper Deposits Near Tokar, Sudan.*

Written for the MINING AND SCIENTIFIC PRESS by W. H. SHOCKLEY.

These copper deposits lie between 17° 30′ and 18° north and 37° 45′ to 38° 30′ east. They cover with their float an area of 500 square miles; the ore in place was found over an area of 130 square miles. They have been but little studied and nothing has been published on them that I know of. The only engineers who have visited the region are J. F. Morris and myself; we were there during February to April, 1905.

The region is mountainous, the highest summits rising to 9121 feet on the Erythrean border, at a distance of 50 miles from the sea.

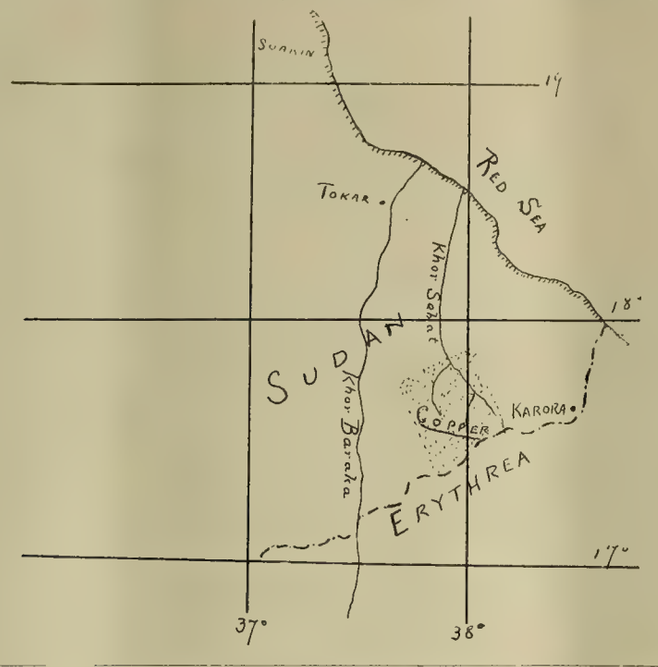
The formation is exclusively made up of schists having a strike a little east of north and a steep westerly dip as a rule. The schists are varied in structure and injected into them are eruptive rocks with well marked crystals. Limestones, sandstone, basalts, porphyries and granites, all of which are found to the west, are wanting.

The slopes facing the sea are covered with dense brush and small trees, and on the higher ranges are forests of juniper. The country is sparsely peopled by Hasas, a tribe of black Arabs, living almost entirely on milk from their sheep and goats. Cattle and camels are also kept. There is much game, gazelle, koodoo, warthogs, bustard and guinea fowl being the principal varieties.

The following assays were made chiefly of float and are only valuable as showing the existence of good ore:

From—	Copper Per Cent.	Silver Ozs.	Per Ton. Dwt.	Grs.
Khor Areirib	2.01	0	6	14
Ibrahim Ledge, near Hubrah	2.03		traces	
Abandob (float)	11.96	2	2	11
Khor Dareb	42.59	20	16	0
Khor Areirib at Abandob (float)	21.25	7	2	17
Khor Areirib, near Abandob (float)	14.33	2	19	0
Khor Humrik (float)	nil		nil	
Near Katal Dul	34.24	15	10	0
Small Khor from Areirib, near Abandob	5.59		traces	
Mahomed Ledge, Khor Humrik	2.92		traces	

All these deposits are on the concession of the Tokar Syndicate, and will be further studied the coming winter. No other mineral deposits were found. Quartz veins are very abundant in one portion of the concession, and the ground is covered to a depth of several inches for many square miles with quartz float, but all the samples assayed were barren.



Sketch Showing Position of Copper Deposits Near Tokar, Sudan.

The copper float found consisted of rock, stained green by malachite, varying from small pebbles to boulders weighing twenty-five pounds. The float, though distributed over 500 square miles, is nowhere abundant, and it needs careful searching to find it. The Arabs soon become expert in finding float; at first they had great difficulty in distinguishing between the chlorite and epidote rocks, which are common, and the copper ore. Specular iron ore is found as float and also in lodes. This mineral is found in the croppings of the copper veins at Bearhaven, in Ireland, which consist chiefly of white quartz. After sinking a short distance the quartz is replaced by copper ores. This fact I learned from Mr. Morris, who examined these mines recently with a view to reopening them.

By following up the copper float we found a number of lodes and indications of many others which our limited time did not allow us to discover. None of these deposits showed any ore that would pay to ship. It is possible that some of the deposits we found may improve in depth, and further prospecting may find much better lodes than we have yet seen.

The strongest outcrop we saw was of white quartz 75 feet long, 10 feet high and 15 feet thick. This showed many small stains of malachite. Strata of schist, impregnated with copper, were found in many places varying from lenses 40 feet long, with a width of a few inches to 4 feet, to a vein a foot wide and extending for several hundred feet along the surface. The largest deposit showed copper stains in a space 100 feet wide by 200 feet long. The staining did not cover the whole space; the largest outcrop here was 15 feet long by 6 feet high and 2 feet wide. A sample taken here gave 2% copper.

*See illustrations front page.

The Ventilation of Mines.

NUMBER IV.

Appliances for Regulating Air Currents: The use of doors and stoppings for systematizing the ventilation of metalliferous mines has not had the attention which its importance deserves, the currents being generally allowed to travel haphazard through the mines. The smoke and vitiated air from lower workings are consequently often found passing into upper ones to the detriment of the men there, when by a little trouble they could be diverted into a return way in which they could do no harm. Each level should, as far as possible, be made a separate "split" from the downcast current, the air being guided through the stopes above it and thence into the main return. Frequently it is not practicable to make each level a separate split, and then two or more may have to be worked on one split, but the more the principle of ventilating the mine in sections can be carried out the more thoroughly it will be ventilated.

The regulation of the distribution of the air can be carried out by stopping all unnecessary air ways, and placing doors so as to direct the currents into the paths along which they are desired to travel. In our examination of the metalliferous mines we found only two which made regular use of an air door system throughout the mine, namely, the Sons of Gwalia and the Ivanhoe, and in both the evidence of witnesses showed that their construction had been attended with great improvement of the ventilation. In the Sons of Gwalia the main shaft is an upcast, the downcast air coming from the surface into the mine through winzes and stoped-out ground, and in order to drive it to the bottom levels it proved absolutely necessary to use doors to prevent it returning to the upcast by the shortest route. In the Ivanhoe case the object of the air doors is to carry the downcast air through the main shaft into the bottom of the mine before allowing it to escape upwards through the workings. In the Lake View Consols mine good use is made of air doors at one or two important points, and in the Ida H. mine, near Laverton, we noticed a well-considered plan of using bag doors to good advantage, but in the great majority of the mines visited there was very little attempt made at any regulation of the air currents. Undoubtedly the judicious use of doors and stoppings would be of the very greatest advantage in almost all mines. In our opinion it should be incumbent on every mine to show should be marked, in order that consideration of this the course of its ventilating currents on suitable plans and sections, on which also all doors and stoppings question should be constantly forced upon the attention of the management, and come prominently under the notice of the inspectors of mines.

Devices for Mechanical Ventilation: A great many different devices for mechanically assisting the ventilation of metalliferous mines were mentioned by witnesses as being used in mines with which they were familiar here and elsewhere, from the large ventilating fans used in collieries to hand-driven fans, water jets, and other simple appliances employed in ventilating small portions of mine workings. There can be no doubt that, in order to insure a thorough and constant ventilation throughout a mine, the use of a powerful fan is the most certain method of attaining the desired end, and that in very many cases where the natural ventilation presents difficulties, the best solution would be a fan installation. The case of the Sons of Gwalia mine seemed to us one which could best be dealt with by a fan. Instead of having the main shaft the upcast, it would be much preferable to have it the downcast into the mine, which could be brought about by putting an exhaust fan on the small shaft, which is the present principal in-take of air, and enlarging the air-way from this through the workings. So long, however, as a fair amount of natural ventilation can be obtained in metalliferous mines in the course of opening them up in the ordinary way, it is hard to persuade owners to go to the expense of installing mechanical ventilation on a large scale, even though in many cases such ventilation would be so much superior that economy, instead of expense, would result. It is somewhat difficult to convince managers that this might be possible without direct comparison of cases where one system has been tried against the other, which are not available in this State; but the experience of coal mines strongly supports the contention that mechanical may be even more economical than natural ventilation, notwithstanding the obvious expense of the former as shown on the cost sheet. Should it enable the working force underground to do only 1% more work in the same time, there would evidently be a very considerable credit to put against the debited cost. That the state of the ventilation does affect the working efficiency of the men employed can not be disputed, especially when the mines are hot. With better ventilation, not only is it possible for men to work longer, on account of more rapid clearing of the smoke from blasting, but the lowering of the temperature brought about also enables them to exert themselves to better effect and do more work. The observations of Dr. Haldane as to the effect on men of high temperatures underground show very strikingly the impossibility of performing vigorous exertion when the workings are very hot and moist. That the temperature may be greatly reduced by ventilation was proved in the driving of the St. Gothard tunnel, where, "before the fan was brought into operation, the temperature used sometimes to be as high as 107° F., with 97% of moisture; but by artificial ventilation the temperature fell to 81° F., subsequently to 74.5° F."

Any of the well-known types of fans used for colliery ventilation may be used also for metalliferous mines, either driving air into the workings (plenum system) or exhausting it out of them (vacuum system), and the choice is a matter for individual consideration.

In the system of ventilating mines by large fans at surface, either blowing or suction, the mine excavations themselves are the principal conduits for the air. Another system, however, is often applied, especially in conjunction with natural ventilation, namely, that of blowing or exhausting the air through pipes. Root's and similar blowers are often used for this purpose, driving or drawing air through pipes into or from the places where ventilation is required. In the blowing system the pure air is confined to the pipes until it reaches the points of discharge, and all the smoke and vitiated air have to travel back through the mine passages; while in the exhaust system the pure air travels inwards to the faces through the workings, and the fumes are removed in the pipes and do not pass over the workmen to any extent. When the air is blown in, however, there is an advantage in the fact that the current can be sent forward some considerable distance from the end of the pipe, while with an exhaust there is little current perceptible a few feet from its end. The blast is, therefore, much preferable in clearing ends of smoke, as it is impossible to keep pipes right up to the faces.

Although the main ventilation of a mine may be very good, it generally happens that development work must be carried on so far ahead of any possible connections that some means must be adopted of carrying a current of air into them. This can occasionally be done by bratticing or by the air-sollar system, as already mentioned; but usually pipes of some sort are the most applicable method. Very generally, however, those used are much too small. Small fans and blowers driven by hand, or by water power, if available, or by a small compressed air engine, or by an electric motor, are often used successfully in such cases, causing air to pass in from a well ventilated part of the mine and removing the vitiated

air. They may be worked on the plenum or vacuum system, as the operator may consider most advisable. Where electric power is available in a mine, the use of small high-speed fans driven directly by motors affords a very flexible system of air supply; and where there are no electric leads a small engine, worked by compressed air from the rock drill mains, also permits a very convenient installation. Where there is a good deal of water allowed to pass from the higher levels to a pumping station lower down in the mine, the water may sometimes be made use of at the lower level as a source of power, being brought down in a pipe and used on a small Pelton wheel or other motor. Where there are Cornish pumps at work, the old "duck machine" or Hartz blower may be used very successfully. If high pressure water is available, as above, or can be obtained from a small pipe let into the rising main of a pump, it is often utilized more simply by merely turning a jet into the bell mouth of a ventilating pipe, the jet driving the air forward. The jet may similarly be arranged to exhaust. In the Ida H. mine we were shown another application of the water blast—a simple variation of the old and well known "trompe," the air being carried down by a stream of water from a rose in such a way that its only outlet was through the ventilating pipe. Air driven in by a water blast is often much liked by the men, on account of its coolness and sensation of freshness. In dry mines, however, either hand power, electric power or compressed air must be resorted to to produce the ventilation. One of the most convenient ways of employing the compressed air to produce a draught, either inwards or outwards as desired, is to use it as an injector, by introducing a small pipe through the side of the ventilating pipe and fitting it with a right-angle bend and small nozzle, so as to deliver a jet of air along the axis of the pipe. A Korting injector may be used as a more elaborate form of the same device. The jet device was employed in the Sons of Gwalia mine, but was dismantled at the time of our visit; we were informed by witnesses, however, that it had been very successful. It was also used in a long crosscut, some 1300 feet or more in length, made some years ago in the Queen Margaret mine, at Bulong, and was regarded as most successful by the manager—an opinion corroborated by some of our witnesses who had seen it in action. In both these cases the jet was turned into ordinary 6-inch or 8-inch galvanized iron ventilation piping.

The convenience of using a blast of compressed air from the mains to blow out the smoke from working faces after firing, makes up, in the opinion of many practical men, for the admittedly high cost of this method of air supply, and it is the means at present in almost universal use in our mines. We have shown, however, that the air so driven in is far too small for adequate ventilation, and ordinarily it is set free too far back from the face, at the coupling from the air hose, to have the best effect, and comparison of the horse power required to deliver a certain quantity of air by fans or blowers with that needed to supply the same amount as highly compressed air, proves that the latter method is absurdly more costly. It also has a great disadvantage, in many cases, in raising a large amount of dust. The difficulty of maintaining large and light ventilation pipes close up to the firing points is admittedly so great as to be almost impracticable, and the use of large, strong pipes means serious cost. We would suggest, however, that the following compromise system might meet the difficulty and would be worth practical trial: Large, light ventilating pipes exhausting to the shaft, either by furnace draught at surface, or, better, by exhaust fan, to be carried to, say, 200 feet from the face, and continued to 100 feet from it by stronger spiral-rivetted piping of the same diameter, the line to be extended from time to time by carrying forward the strong pipe and introducing behind it fresh connecting lengths of the lighter pipe. Then, to bring the smoke back to where the exhaust pipe can reach it, carry in as close to the face as practicable a strong iron pipe 4 or 5 inches in diameter—an old compressed air main would do—with the injector jet in it, by which a blast may be sent in which will reach the face; the injector to be attached to the air mains at the rock-drill hose coupling by a short length of hose. The smoke would then be blown out to the exhaust pipe and drawn out by it. In many cases of rising and sinking winzes the injector pipe alone would be required, the smoke being carried away by the natural currents when it reached the level. This plan might not give so high an efficiency as an electrically driven fan, but would, we think, be more adapted for the rough usage of mine work and be a long advance on the use of compressed air directly from the mains. The injector system uses a considerable portion of the power contained in the compressed air in moving a relatively large volume of other air, but the power in what is blown off from the mains is almost absolutely thrown away.

Where steam pumps are used in a shaft, the exhaust steam from them may be usefully turned into the bottom of a large ventilating pipe or wooden box placed in the shaft and connected with branch pipes into the levels. The warming of the air in the column up the shaft by the exhaust steam increases the draught very materially by accentuating the differences of temperature on which the movement of the air depends. The steam pipes leading down to the pump are sometimes placed inside a large surrounding ventilating pipe for the same reason, and also for the sake of a slight economy in steam, through the steam pipe passing through the warmer air instead of going down the shaft uncovered.

(TO BE CONTINUED.)

Placer Mining in Alaska.*

NUMBER V.

For moving up the cars within reach of the dipper as each one is filled, the device shown in Fig. 10 is used. This was devised by W. S. Purington, and has been in successful use for five years. The long cylinder, made with casting to attach to the shovel, here shown on the near side, contains a piston of equal length, which is supported on suspended track and wheel as it leaves the end of the cylinder. To the near end of the piston a cable passing over a sheave is attached. The other end of the cable is hooked to the corner of the gravel car, steam is turned into the near end of the cylinder, and as the piston travels back toward the forward end of the shovel car, the gravel car is hauled by the cable an equal distance—from 5 to 7 feet, as may be required. Steam is then turned into the cylinder, allowing the piston to return and the cable to free itself; the cable is unhooked and pulled by the car man to the following car and hooked in readiness to pull it along. The amount of steam and the time consumed in the operation are so small as to be almost negligible. By passing the cable around the body of the shovel car over a second sheave, the cars on the opposite side of the shovel can be moved, when the relative position of the shovel is reversed.

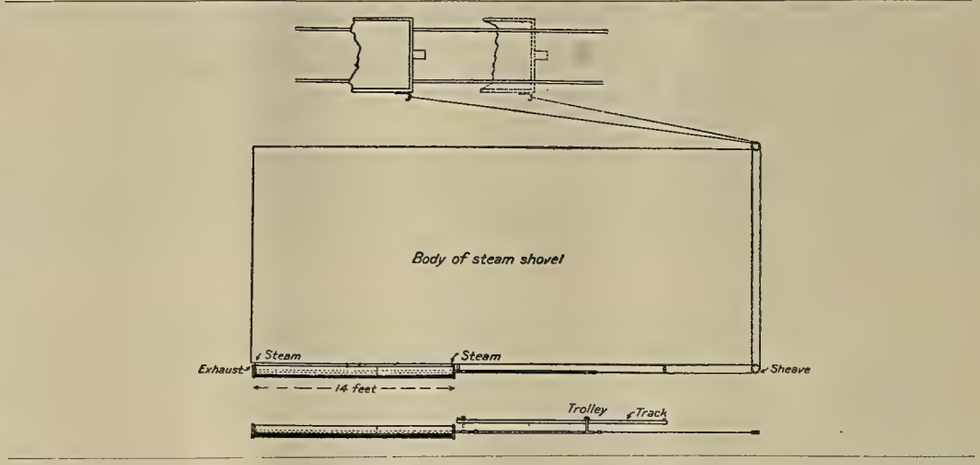


Fig. 10.—Pulling-Up Device for Steam Shovel.

Dipper chains are generally preferable to cables in placer operations, as illustrated by the experience of the shovel dredger in Solomon river. A link in a chain can be repaired where a wire cable can not.

In Anvil Creek plant the present arrangement for dumping the cars at the sluice is unsatisfactory and will be changed. Self-tripping, two-way dumping cars will be substituted for the man who trips the cars. The sluice presents no new features. It is 500 feet long by 32 inches wide by 36 inches high at the dump box, and narrows to 26 inches wide by 24 inches high, in 10-inch grade, and is furnished with angle iron riffles. The cost of digging, tramming and dumping the gravel to sluice is said to be 12 cents per cubic yard.

In the Anvil Creek operation the actual working cost of digging the gravel, tramming and hoisting, and tripping the cars to the sluice box is given below, as estimated by the superintendent—the figures covering 810 yards in twenty-four hours, and including superintendence on the ground, labor, crude oil fuel at $3 a barrel, lubricants, etc.:

COST OF STEAM SHOVEL WORK AT ANVIL CREEK, ALASKA, PER CUBIC YARD.

Digging	$0.045
Tramming to incline	0.025
Hoisting	0.018
Dumping	0 011
Proportionate superintendence on ground, and incidentals	0.021
Cost per cubic yard	$0.120

Although the cost of 12 cents on Anvil creek appears attractively low, it must be remembered that it does not take into account the labor of shovelers cleaning bedrock after the shovel. This operation, unfortunately, can rarely be dispensed with, at least in portions of the ground, and it will naturally increase the cost of getting the auriferous material into the cars. In some places in Alaska the slabs and leaves of bedrock must be scraped with brooms in order to recover all the gold. The prospective steam shovel miner should keep in mind the fact that a machine which will handle a large quantity of material, however cheaply, is of no avail unless it can succeed in extracting a large percentage of the values.

The steam shovel plant at the junction of Bear creek and Klondike river occupies the flood plain of the latter stream, a fact that influences greatly the economical excavation and disposal of material, since both lack of grade for washing gravel and dump for disposal of tailings must be supplied artificially.

This steam shovel digs in a pit 20 feet below the surface of the flat. The dipper empties into cars which are pushed by hand to the foot of an incline and raised by steam winch to the platform of the washing frame, where they are dumped by hand into a hopper. The material passes through a trommel, and the oversize falls into a self-dumping carrier and is elevated to dump. The undersize passes over tables and through sluices, and the fines are also raised by steam, a scraper being employed to secure dumping ground. There are, therefore, four distinct elevations, viz., by the shovel, the gravel by the tram, the coarse tailings by the bucket, and the fines by the steam scraper.

The pit in which the shovel works varies in depth from 20 to 24 feet. The gravel lies beneath 3 feet of muck, is generally mixed with considerable sand and extends to bedrock. The material is well rounded and contains but very few stones (but 1%) that are over 18 inches in diameter. Considerable black sand is found in the cleanup. In spots the ground is frozen, necessitating the occasional use of steam points. Steam is conveyed across the cut in a covered steam pipe hung from a stretched cable. A schist bedrock, generally hard, is excavated for about 2 feet by the shovel.

The shovel weighs 35 tons and revolves 360° upon a turntable. The dipper holds 1 cubic yard, and the machine has a capacity of 1000 yards in ten hours, though this cannot be obtained owing to inadequate tramming facilities. Its cost on the ground is about double that charged by the manufacturer. The boom, when horizontal, reaches 22 feet beyond the bow, but when at level of track only 14 feet. Three-quarter inch cables are used in transmitting power. The faults of cables in steam shovel practice in inaccessible localities have been commented on above. The dipper contains no new features. Prongs are added to save lip, the central one being longer than those adjacent. The machine has three engines and uses in all about 40 H. P.

For conveying material three cars of 2 yards capacity each are used, running on a 3-foot gauge track with 16-pound rails. The cars are pushed by hand to the foot of an incline, which has an angle of 22° and extends 100 feet, and thence elevated by cable connected to a 40 H. P. hoist. Two hundred and fifty cars are usually raised in ten hours. On reaching the platform the cars are dumped by hand and returned by gravity to the foot of the incline.

From the hopper into which the cars dump the gravel is fed into a revolving trommel 16 feet long and 3 feet in diameter supplied with a worm upon the inner surface and punched with holes varying from ½ to 1½ inches in size. The rate of feed is regulated by hand, a gate being raised and lowered when necessary. Water is supplied to the trommel by a 6-inch longitudinal pipe. All oversize passes directly over a sheet iron chute into a square hopper, from which it falls by gravity into a self-dumping carrier and is elevated approximately 40 feet upon a dump. A 10 H. P. winch does this duty. The hopper is furnished with a heavy iron gate, raised by the steam winch running the self-dumping carrier, and is lowered by its own weight. The fines (the material passing through the trommel) fall directly on gold-saving tables similar in design to those used on many gold dredgers. The tables, which are fed by two 4 inch pipes, are six in number (three on each side of the trommel), and have a gold-saving surface of 80 square feet. They are fitted with expanded metal and cocoa matting riffles, which prove to be very efficient, the greater part of the gold being caught near the upper end of the first table. The material then

*Bulletin 263 U. S. Geological Survey.

passes to a longitudinal sluice, which consists of eight boxes 22 inches wide, furnished with Hungarian riffles constructed of 1x3 inch inclined cleats, capped with three-sixteenths-inch iron. The tailings are removed by a steam scraper and elevated upon a dump. The winch for the scraper is 30 H. P. and elevates 400 4-wheelbarrow units 15 feet in ten hours, seven-eighth-inch cable being used. It will be seen that the above double elevation of material must be costly, using as it does, not only much power, but also additional men on separate winches.

The greater part of the water for sluicing, 300 inches, is brought by flume from Bear creek. The remainder, amounting to 100 inches, is raised from the pit by a series of pumps. A No. 6 centrifugal pump raises the water to the foot of the washing apparatus, from which it is lifted 25 feet by a No. 8 centrifugal and used for sluicing. A 35 H. P. engine does the latter work. An additional pulsometer pump is occasionally used in the pit.

The power plant contains two 60 H. P. boilers and one 50 H. P. boiler, wood being used for fuel. Sixty men are employed about the plant, the daily wage of the laborer being $4 and board. The men work two 10-hour shifts throughout the working season.

The above-described plant will undergo considerable change in the near future, improvements designed to effect greater economy being contemplated. It is planned to haul all material excavated a distance of 2000 feet by locomotive, in trains of six cars, to a washing plant on the banks of Klondike river, where the ground is 8 feet below the upper edge of the pit, and then wash it by gravity water from Bear creek. High water in the Klondike will greatly economize the handling of tailings, and it is hoped the full capacity of the shovel may be utilized.

A machine run on radically different principles from those above is illustrated by a steam shovel on El Dorado creek, in the Klondike region. In this case the use of a tramming system is entirely avoided by so arranging the plant as to allow direct dumping by the dipper into the sluice boxes. In this case the shallowness of the ground and the use of a 50-foot boom permit such an arrangement. The work lies in the creek bed proper and cuts are made longitudinally along the stream, the sluice boxes being moved every three or four days, following the progress of the shovel. This practice alone involves both good and bad features. The practice of dumping directly into the sluice is, theoretically, much to be desired, embodying, as it does, only one elevation of the gravel, an arrangement which consumes the least power and time—two all-important factors. The moving of the sluice boxes, however, in this case consumes much time—from one to two days for each move—and, wages being $6 a day and the season very short, constitutes a serious drawback, greatly reducing the capacity of the plant. The boom of the machine, as stated, is 50 feet long and hoists the gravel 30 feet above the cut. If an arrangement facilitating the moving of the boxes could be devised, so as to avoid the long delays caused by this operation, a very satisfactory result might be effected. Such a system requires a relatively shallow bank, however, and it is doubtful whether it is available for steam shovel operations in general.

In this instance the gravel to be taken out is frozen, and continuous thawing must accompany the advancing work. In this work fifteen steam points are driven into the bank to bedrock, where they remain 24 hours, the process consuming during that time three cords of wood. A 25 H. P. boiler is used for this duty.

Water is very scarce at this plant and is used repeatedly, being raised from the pit by a centrifugal pump and carried back to the sluice boxes in a flume. The pump also serves to drain the pit. The sluice boxes have a grade of 9 inches to 12 feet, but, with the water at hand, are unable to keep pace with the capacity of the machine.

The shovel carries a one-yard dipper operated by chains. It is claimed that one cubic yard is moved every two minutes. Bedrock of a slaty nature is taken up to a depth varying from 2 to 5 feet.

The problem of disposal of tailings is a difficult one and has not been solved economically. A steam scraper is used and all tailings must be scraped to one side and elevated. Not only is the expenditure for wood an item, but a man must be constantly attending the scraper while another handles the steam winch.

A tramming system which would convey the material to be washed to such a point as would admit of the disposal of the tailings by gravity, even if a thousand feet or more distant, would be a more economical arrangement, saving, as it would, not only all elevation of tailings, but also all delay in moving the washing apparatus.

Ten men are employed about the plant each shift, occupied in scraping tailings, forking gravel in dump box, running shovel, attending steam points, and in cleaning bedrock at places where the dipper could not effectually work.

The shovel is moved on rollers running on skids, power being obtained from the shovel winch. The dipper is furnished with soft steel prongs which wear very rapidly.

DRIFT MINING.—Northern gold gravel deposits, that are sufficiently rich to warrant the method, can generally be exploited by drifting beneath the overburden at all times of the year. In drift mining creek deposits the gravel is hoisted through shafts, and where bench gravels are worked it is generally trammed through adits. In all portions of the interior of Alaska and in the Klondike the drifting of auriferous gravels has been carried on with fully as much activity in the winter as in the summer. The expense of winning the gold by winter drifting and spring thawing is greater by over $1 per cu. yd. than that of summer work. This is due to the necessity of rehauling and, in many cases, of rethawing the dumps in the separate process of sluicing. In consequence, only the richer ground, running from $6 to $10 to the cubic yard, can be profitably drifted. The price of labor during the winter in the interior is only 25% less than in summer, so that this does not afford a great offset to the increase of cost from other causes. In Seward Peninsula, where the price for winter labor is only $2.50 a day and board, as against $5 in summer, it would seem that winter drifting can be undertaken more generally than heretofore. A reliable operator of Nome is of the opinion that winter drifting operations should be continued in that vicinity where timbering is necessary but thawing is not, and where the gravel can be trammed to surface through adit for $3 per cubic yard, including all expenses of extraction and sluicing-up in the spring. This is less than double the cost of drift mining in the Forest Hill divide region of California, where conditions are eminently favorable.

Neglect to sample is the worst possible practice, as many lamentable failures have resulted from overconfidence in the value of the ground taken out, and the miner who confidently waits for the big wash-up before thoroughly knowing the amount of gold in the material he is handling is frequently doomed to disappointment.

Where timber is scarce and costly and wood for fuel has to be hauled from a distance, it is advisable to consider the entire abandonment of attempts at winter work. The amount of gravel which can be hauled is less and the cost per cubic yard is greater. The time spent in sluicing the winter dump may frequently be more profitably employed in preparing for the summer. The ordinary small rig for drifting operations without timbering is shown in Fig. 11.

(TO BE CONTINUED.)

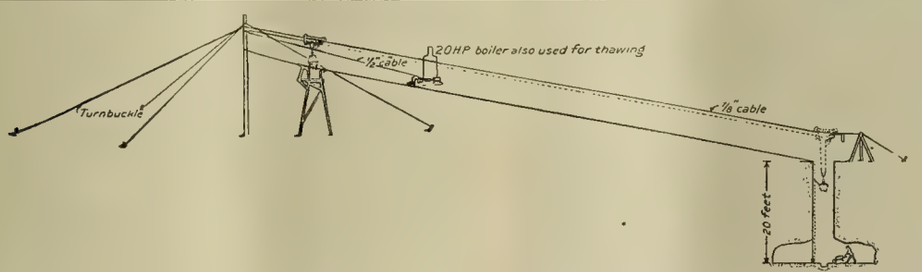

Fig. 11.—Rig for Small Drifting Operations in Alaska.

THE PROSPECTOR.

The samples from Oasis, Cal., were determined as follows: No. 1, quartz, with considerable brown iron oxide. At one end about a nucleal bunch of copper glance is green copper carbonate (malachite) and copper silicate (chrysocolla). On breaking the specimen galena (lead sulphide) was found. There are also indications of the presence of arsenic, and it may also carry gold and silver. No. 2 is feldspar porphyry. No. 3 is the same, but somewhat altered by pressure and shearing. On one side are seen several crystals of galena.

The gold sent with black sand from Burnt Ranch, Cal., is what may be called quartz or vein gold. It is rough and shows not the slightest sign of having been rounded by water wash or attrition of any sort. It is very probable that the vein or deposit is not far distant. A portion of the sand is magnetic, and is mostly altered pyrite—that is, pyrite in a stage of semi-oxidation, being what is known as a "pseudomorph"-limonite after pyrite. Gold when first freed from its matrix is always rough, no matter what the gangue may be. Placer gold is more or less rounded, according to the distance it has traveled from its source and to the scouring agencies. A large nugget may not travel far in a creek bed, and yet be much rounded by the scouring action of the sand and pebbles which are carried along by the water in the stream.

The rock samples from Prescott, Ariz., are: No. 1, a hard, dense, metamorphic rock, which was originally a clay rock. No. 2 is andesite. No. 3 is liparite. No. 4 is quartz-porphyry. No. 5 is granite. The black veinlet on one side is tourmaline. No. 6 is largely epidote and feldspar. The black metallic mineral in scales is specular or micaceous iron, a variety of hematite.

The rock sample from Dorleska, Cal., is hornblende schist. In rocks of this character frequently occur gold-bearing veins. The specimen contains very little silica, but in some localities this class of rock becomes silicified along certain zones, and then often carries gold, silver, copper, etc.

The samples from Constellation, Ariz., are: No. 1, mica schist, of no value whatever. No. 2, muscovite mica In its present condition it is of little commercial value except after being ground into powder. In depth the quality may improve, when it may become valuable for various purposes. Large electrical manufacturing concerns, like the Westinghouse company, are interested in getting a supply of inexpensive mica.

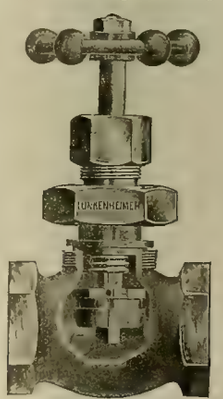
The samples from Burnt Ranch, Cal., are: A, a very siliceous metamorphic rock, originally fine sandstone, now practically a quartzite; b, a very much decomposed rock, impossible to properly classify, but seemingly an altered greenstone, probably diabase or some similar rock. C is principally silica, carrying finely disseminated iron sulphide. It is probably an altered dike rock, such as felsite.

The rocks from Barstow, Cal., are: No. 1, an altered and partly serpentinized limestone. It still effervesces with acids. No. 2 is the variety of volcanic glass known as pitchstone-porphyry or vitrophyre. It contains numerous crystals of feldspar and one or two fragments of stony rhyolite.

The ore from Elk City, Idaho, is evidently a portion of a silicified dike rock, possibly diabase or diorite. It consists principally of quartz with probably 3% pyrite (iron sulphide). By careful examination with a high power lens a few minute yellow spots were seen which may possibly be calaverite, but the quantity is so very small as to make positive determination impossible.

Improved Regrinding Valves.

The Lunkenheimer Co. of Cincinnati, Ohio, manufacturers of the Lunkenheimer engineering specialties, have made a number of changes on their regrinding valves, increasing the weight of the valve as an additional precaution against rough handling while attaching, etc. The medium pattern valves are guaranteed to stand a working pressure of 200 pounds per square inch, and the extra heavy pattern up to 300 pounds per square inch. They have also altered the shape of the valve, which improves its appearance and increases the area through the valve permitting an unobstructed passage, the area being more than equal to that of the connecting pipe. To insure a perfect and strong joint between the pipe and valve, the pipe threads have been made considerably longer, thus overcoming the danger of stripping threads. All sizes of the valves now have lock nuts on the hand wheels, which facilitates the taking apart and assembling of the valve for repairs. Referring to the sectional illustration, it will be



Improved Lunkenheimer Valve.

noticed that the hub which carries the operating stem is secured to the body by a union connection, which, in turn, screws over the shell of the valve body. By means of this construction, it is impossible for the hub and the body to become corroded together, as the thread which holds the union ring to the body is protected at all times from the action of the steam, the joint being made between the flange on the hub and the neck of the body. This tends to make the valve rigid and strong. The disc is held loosely to the stem by means of a lock nut, and will therefore adjust itself to the seat readily. The stem is fitted with a strong, durable and long thread, and the manufacturers emphatically state that the valve is easy to operate and that there is practically no exertion necessary to tightly close even their largest valves, as the hand wheels are so proportioned in respect to the seat opening that no additional leverage need be applied to the hand wheel to facilitate the operation of the valve. To regrind the valve, the bonnet ring is unscrewed and the trimmings are removed from the body. A wire or nail is placed through the lock nut and stem, a little powdered sand or glass and soap or oil is placed on the disc, and the trimmings are again placed in the valve and reground.

Gold Dredging in California.*

NUMBER IV—CONCLUDED.

There are two classes of sluice and table paving used in the Sacramento valley gravels to save fine gold. One is ordinary Hungarian or cross riffles with quicksilver, and the other cocoa matting covered with expanded metal, 2½-inch mesh. These are nearly equally satisfactory, so far as the managers report. However, in most cases each manager has used only one kind and made no comparison. Where comparison has been made the preference seems to be in favor of the riffles with quicksilver. There is no arsenic or anything else present to prevent a rather free amalgamation. Yet there is present so much black sand which would prevent the gold from reaching the quicksilver that it is found necessary, in putting in the riffles, to insert between them stones that stand up above the tops of the riffles in order to stir up the black sand and allow the gold to go to the bottom. On the cocoa matting the expanded metal, in diamond shape, about ¼ inch deep, is placed for the same purpose.

One of the most careful managers at Oroville states: "We originally used cocoa matting on our dredger, but later installed the riffles and quicksilver and increased our gold-saving area 85 square feet, by utilizing the space in the distributing box directly under the screen. We are going to use riffles and quicksilver in our new dredger."

Under the screens on the first tables quicksilver in large quantities held in place by riffles is used with a view to bringing the fine gold into contact as it drops from the screens. In this respect shaking screens do better work than revolving screens, because they let the fine material down over a larger surface.

Both at Oroville and Folsom, and even at Yuba, it has been found that gold—even the very finest gold—if brought in contact with the quicksilver, will amalgamate without much difficulty. In Colorado and in Idaho, where there is fine gold, and dredging has been done on rather an extensive scale, it has been found impossible to make any consequential saving of gold with quicksilver, owing to the presence of arsenic or something else. The result is that cocoa matting or some similar appliance must be used. It would appear that where the very fine gold amalgamates freely, riffles and quicksilver are preferable to cocoa matting.

As platinum does not amalgamate with quicksilver, there is a greater loss of this metal when riffles and quicksilver are used, than when cocoa matting and expanded iron mesh are used.

CREW OF A DREDGER.—The following table will give an idea of the number of men commonly required on dredgers. The wages named are those usually paid at Oroville:

CREW FOR ONE DREDGER.	Per Day.
One foreman, at $5 per day	$5 00 to $ 5 00
Three winchmen, at $3 to $3.50 per day	9 00 to 10 50
Three oilers, at $2 to $2.50 per day	6 00 to 7 50
One blacksmith, at $3.50 per day	3 50 to 3 50
One helper, at $2 to $2.50 per day	2 00 to 2 50
Two Chinamen, $1.75 to $2.50 per day	3 50 to 5 00
Total	$29 00 to $34 00

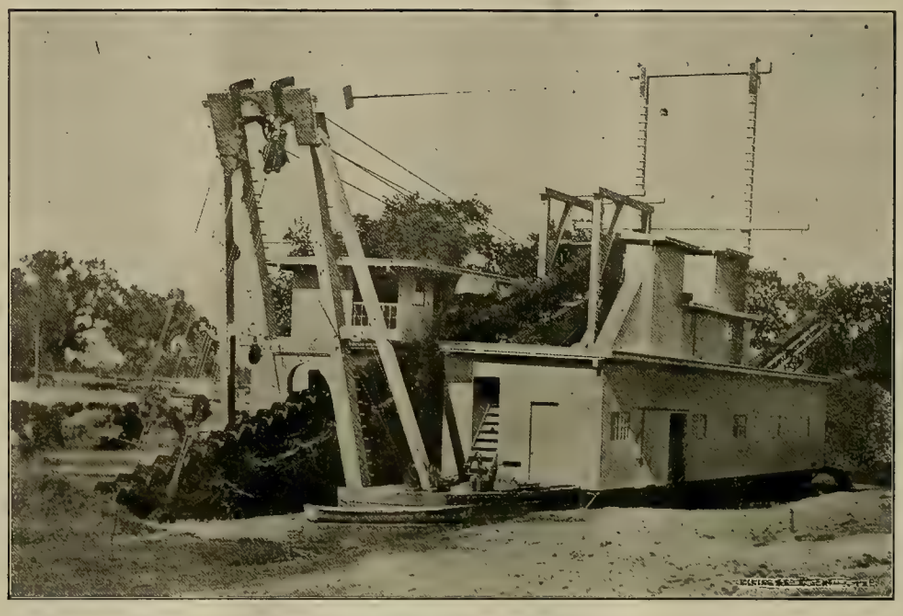
In addition there is a superintendent, whose time is generally divided among several dredgers. The winchmen and oilers work eight-hour shifts, while the blacksmith and helper work ten hours. The Chinaman clear the ground of brush and trees, "bury dead men," as making fasteners for the lines is called, and do general chores.

The depth to which the present dredgers may dig is from 30 to 60 feet below the water level, the latter depth being reached by the new dredgers on the Yuba. That greater depths may be reached is only a question of increased strength and power and longer digging ladders. These work at their best, it is claimed, on an angle of 45°.

WORKING COSTS.—A majority of the dredger companies in California have given statements as the approximate actual cost of dredging per cubic yard. These costs vary from 2.36 and 3 cents to as much as 8½ cents. It will be seen that where a return of 3 cents or less is given, it is for a new dredger with all the advantages of the latest ideas as to strengthening the parts of the machinery, and that there have been no breakdowns and consequently very little, if any, costs for repairs. The labor bill has been very light, for the running time has been full. The owners of this dredger have stated that their costs will be materially increased in working longer periods of time, through the loss in actual working time caused by breakdowns and the cost of new parts and for repairs.

So it is only those reports on dredgers which have been in operation for a long time, say three or four years at least, that are of much value in determining what would be the average cost of working under similar conditions. However, one must remember that the lately built dredgers are more strongly made and afford less opportunity for breakage and repair costs. The record for low cost is 2.36 cents per cubic yard with a new dredger.

In studying these reports, one must consider in respect to the different districts: (1) The cost of power; (2) the rate of wages; (3) whether the company reporting has one or several dredgers under one management; (4) whether the company has its own machine shop or not; (5) the hardness of the ground, and this particularly as to whether blasting with powder is necessary; (6) the size of the buckets; (7) whether the buckets are alternating or close connected; (8) whether belt or bucket conveyor is used; (9) whether revolving or shaking screens are used; (10) whether a sand pump is used; (11) the age of the dredger.



A California Dredger in Operation.

A Modern Dredger in Construction.

Only one company operating at Folsom returns cost of working, and that at 5 cents. At Folsom the cost for power is 0.65 of a cent per kilowatt hour, while at Oroville it is 1½ cents.

Some idea of the difference in cost per cubic yard between operating one dredger and operating several dredgers under one management may be had from the estimate of the Oroville Gold Dredging and Exploration Co.

Of course, under certain difficult conditions a dredger of small capacity may be preferable, but under most ordinary conditions, such as at Oroville, Folsom, and other places in the Sacramento valley, the greater the yardage capacity of the dredgers, the lower the cost of working.

It may be said that the cost of repairs is still excessive, but this item of expense has been reduced from year to year since the first successful dredger was put in operation in 1898. It may be said, too, that if the dredger builders had not increased the strength of the buckets, the quality of steel used, and in many other ways strengthened all the straining and wearing parts of the dredgers, it would now be impossible to build, as they propose doing at Folsom, a dredger with 13 cubic feet buckets, or even 7 cubic feet buckets. A comparison of costs of a new dredger with those of an old dredger of same size and type is therefore unfair.

Whenever the Bucyrus type of dredger is mentioned, it is understood to have close connected buckets, a shaking screen, belt conveyor, and riffles and quicksilver on the sluicing tables; while the Risdon dredger has alternating buckets and links, a revolving screen, bucket conveyor and cocoa matting, with expanded metal mesh covering them on the sluices.

It is for the dredger builders and for the skilled managers at Oroville or Folsom or elsewhere in the State to more seriously consider this question of cost of repairs than anything else, except, of course, the question of saving the present loss of fine gold, which is far greater than most of them suppose.

PROSPECTING AND EXAMINATION OF CONDITIONS.—It may seem a simple thing to say that a careful

*Bulletin 36, California State Mining Bureau.

study of all the conditions should be made before a dredger is ordered, no matter how large the values in gold may be found to be. The values may in many cases be of almost minor importance, or of no importance, where, as is the case in some of the mountain districts, the hardness of the bedrock, with much of the gold on the bedrock, has prevented dredging very rich ground. There have been many failures in California, and all because proper examination of the ground was not made before the dredgers were built.

In Trinity county, in one case, a dredger was put in and failed and has been dismantled because the fact that the ground was valueless was not proved. There is another case where a dredger was built and operated for a time on very heavy ground, but it was so weak in construction that it failed and was dismantled. Now another company is building a dredger to work the same ground, with every promise of success. There are similar wrecks in the Oroville sea caused by incompetent pilots.

It has been said in regard to sampling, that which will apply to any other part of the examination of a dredging property: "Haphazard and occasional sampling and assaying are worse than useless. They lead to great losses of valuable capital, frequently to the total abandonment of good properties, and, worse than all, to a false sense of satisfaction that discourages improvement by denying its necessity."

Conditions to be considered: The following are some of the conditions, etc., to be determined by drilling and other examination prior to determining whether the ground may be dredged, prior to estimating costs, and prior also to determining the kind of dredger to be used:

Value in gold per cubic yard, and its distribution.
Hardness of gravel.
Total depth of gravel to bedrock.
Depth of gravel from water level to bedrock
Whether level or rough on surface.
Size of bowlders.
Amount of clay in gravel.
Hardness of bedrock.
Whether bedrock is level or not.
Water—amount of supply, and cost.
Cost of power.
Wages.
Cost of transportation.
Cost of supplies.
Cost of repairs.
Cost of land.
Climatic conditions.

Hardness of Gravel: Generally speaking, any gravel that may be picked may be dug with the dredger, without the use of powder. If it is so hard as to require blasting, the cost per cubic yard will be increased from 2 to 3 cents.

Depth of Gravel: The most satisfactory depth to dredge with some newer dredgers now in use is not to exceed 60 feet, but they will work down to 70 feet. In order to work to a greater depth than 70 feet, some changes in the digger, stacker, and power would be required.

Level Surface of Gravel: With an uneven surface the use of headlines is not so satisfactory as spuds.

Size of Bowlders: Very large bowlders can not be handled with the ordinary dredger, and much gravel may be left on the ground. The size of the bowlders must be considered also in deciding whether to use an open or close connection of buckets in the digger, the latter rendering it impossible to handle the larger bowlders.

Climatic Conditions: Of course, freezing weather will prevent washing the gravel, and cause a stoppage of work. In the northern latitudes of Montana and Alaska, the season is commonly not more than five months long.

Clay in Gravel: The clay will not permit of clean dumping from the buckets, and not only is much gold carried back to the bottom and lost, but the yardage capacity of the dredger is decreased. Besides this, the clay carries off gold and fine amalgam from the sluice boxes.

Hardness of Bedrock: If the bedrock is too hard to dig, gold in the crevices or lying near the bedrock is lost. The drill will locate the position of the pay which may not be too close to the bedrock.

Level Bedrock: The bedrock should be near enough level to permit the boats to float over all the ground to be worked.

Presence of Arsenic: The presence of arsenic or anything else that will prevent free amalgamation makes the use of quicksilver and riffles of little avail, and cocoa matting, plush, or other such means must be adopted to save the gold, especially where it is in fine particles.

Drilling: Nearly all this work in the Sacramento valley districts of California has been done with Keystone drills, No. 3 traction. Owing to the presence of water in the gravel in most instances, it has been found impracticable to sink shafts. The cost of the drill, including freight, etc., is about $1900 complete. Three men are required to work it, with wages from $3.50 to $4, and $2.50 and $2 per day. To this must be added the cost of fuel, water, repairs, etc., and wages of one or two men to do the sampling. The sampling, if properly done, would require a skilled man, and his pay might add much to the cost. The total cost per day to run the drill and do the sampling varies from $15 to $30. About 12 or 15 feet per day is a good average speed for sinking in the gravels of the Sacramento river basin. With larger bowlders and harder ground the cost might be materially increased.

In comparatively shallow ground, where there is not much water, it is much more economical to sink shafts than to drill, and the results will be found more satisfactory.

The following table shows the form in which notes of sampling have been kept in making an examination at Folsom:

Column marked "a" indicates colors of fine and flour gold, smaller than "b" size.
Column marked "b" indicates colors of size estimated 25 to 1 cent.
Column marked "c" indicates colors coarser and heavier than "b" size.

APRIL 11, 1904—HOLE NO. 1.

No. of feet.	Material.	No. of Colors. "a"	"b"	"c"	Remarks
0	Surface line.				
1 2 3	Sand and gravel.	2	0	0	One pan.
4 5 6	Loose gravel.	6	6	0	Hole 4½ feet 6 P. M. April 12, 7:30, two pans started.
7 8 9	Loose gravel.	30	8	2	Five pans.
10 11 12	Loose gravel.	15	4	0	Rockered.
13 14	Bedrock.	10	0	0	No water, rockered.
Total.....		63	18	2	

GENERAL REMARKS.—Drilled 14 feet in the clay, being a volcanic ash; first few feet a light brown color, then whitish, down as far as we drilled. This clay is called "bedrock."

Diameter of drill, 5⅝ inches; diameter of shoe, 7 inches; casing, 5¾ inches, inside diameter.

By proper sampling is meant the determination, from a comparatively small sample, of the values in a much larger volume of the same material. Care, judgment, and experience are necessary, and all such work, whether done by drilling or by sinking shafts, should be put in charge of an experienced man. Gravel lifted by drills or taken from a shaft must be accurately measured or weighed, and proper allowances made for expansion when loosened. Allowance must be made for excess of bowlders not sampled, and for excess of gravel beyond the normal width of the drills that may come in and be lifted.

Prospecting: There is no rule as to the number of holes that should be sunk. More drill holes would be required, to give satisfactory results, than shafts. If the values are comparatively evenly distributed over the tract to be examined, fewer holes would enable nearer approach to a correct estimate of values than where the pay is uneven. In districts where the character and values are comparatively well known in parts of the gravel that have been sampled, less careful examination is necessary on intervening tracts in order to determine most of the conditions and values.

Errors in sampling frequently occur from the squeezing in of material around the bottom of the casing, so that more gravel than is called for by the size of the hole is lifted. A check on this is to drill and pump in a section of a foot or so and weigh the material. Sliming and consequent loss of gold sometimes result when too long a period of churning transpires before pumping the hole.

The casing should be kept driven below the point of drilling, whenever possible.

Fine Gold: When the gold is as fine as at Oroville or Folsom, the pan and rocker will not save all of it, but will save all that the best saving tables in the dredgers will save, and may save considerably more. But when it is considered that if some of the finest gold now being saved be shaken up in a bottle of clear water it will take one or two hours to settle, there can be no question that some is lost whether the sampling is done by panning or rocking, and also in the sluicing. How much this is could be determined by gathering samples, especially of the water from the pans and rockers and also at the ends of the sluices and subjecting them to proper tests. It would seem that this work should be undertaken and carefully carried out by the dredger people. If much gold is being lost, there is a spur to ingenuity in devising means for saving it.

Temporary and Permanent Headframes.

Not infrequently it becomes necessary to construct a permanent headframe over a pre-existing temporary wooden structure, while the work of mining continues, using the wooden frame. The accompanying engraving illustrates how this was accomplished at the Mizpah mine at Tonopah, Nevada. The old two-post wooden frame was used daily, while the new steel frame was being placed. In some cases the hoisting plant is located opposite the end of the shaft to facilitate the installation of the permanent hoist.

Steel Headframe Building Over the Temporary Wood Frame.

THE recent ousting of A. J. McMillan from the management and directorate of the Le Roi mine at Rossland, B. C., will probably result in ending a long-fought battle for control of that property. It is thought by those competent to judge that if the conflicting interests are harmonized, and the Center Star and certain other properties be consolidated with the Le Roi, the proposition can be placed on a paying basis, if the metallurgical branch of the enterprise is properly handled.

WOODEN TANKS will last longer and give better service if the outside of the tank is painted. A mixture of coal tar and asphaltum in equal parts, applied hot, makes a good coating for the inside of tanks.

Cyaniding Raw Sulphides.

At Barberton, S. A., a somewhat unusual operation was recently undertaken in the cyanidation of iron sulphide concentrates assaying about $60 per ton in gold. Ordinarily only low-grade material is treated by the cyanide process, but the success of the attempt in South Africa, here described, indicates that high-grade ores may also be successfully treated by this process under favorable circumstances.

The work was done by A. L. Edwards, and is thus described by him in the Journal of the Chemical, Metallurgical and Mining Society of South Africa:

As the results from several experiments proved favorable, the company decided to cyanide their accumulated concentrates, some 210 tons in quantity, assaying 60 dwts. to the ton.

The concentrates were ground in a small ball mill, and passed through a 1600-mesh standard screen, sampled, thrown into treatment vats, water washed, and four pounds of lime per ton of concentrates added, a first weak (.05% KCy) wash was run on, leached off, then a second medium (.1% KCy) solution run on, and leached off, and the concentrates were turned over. A strong (.75% KCy) was then run on, and allowed to remain in contact for twelve hours, the solution drawn off, and all dissolved gold washed out as rapidly as possible; this treatment was repeated on three subsequent occasions, with the result that the extraction was brought up to 93%.

The time occupied in treatment was forty days, but this could have been reduced to 25% had time been allowed for grinding the concentrates to a finer state of division.

The cost per ton for cyanide was 12s, zinc 4d, lime 3d and labor 5d (the costs of power, lubricants and supervision are not available); it will be seen that the solvent is responsible for 12s of the 13s, the high consumption being due to the unroasted state of the concentrates. An experiment carried out on a quarter ton lot of roasted concentrates showed a cyanide consumption of 8s per ton on a twenty-eight days' treatment.

It was known beforehand that, to successfully treat concentrates by percolation, roasting was essential, but the company having "shut down," time did not allow of this being done.

The leaching was good and the precipitation excellent, and the action so strong as to necessitate the flow being reduced to two tons per hour.

Two-thirds of the gold, 390 ounces, was precipitated in the first three weeks.

In the strong box only clean zinc was used, while the zinc-lead couple was used with good effect in the weak box, the solutions leaving at from six to eight grains. The strongest solution used was .75%, and the weakest .08% with a final water wash.

Towards the end of the treatment period the "white precipitate" made its appearance in the weak box.

I am informed that chlorination charges are:

1.	£4 per ton for treatment	£4	0 0
2.	15% of gold contents not paid for	1	18 0
3.	Railage at 20s per ton	1	0 0
	Making a total charge per ton of	£6	18 0

This sum deducted from the value of the concentrates means roughly 50% of the value.

Now, if we put the total charges of cyaniding at 40s (a liberal margin) we find that the cost of treatment locally is only 15% as against 50%. It is hoped that these notes may prove of service to members and associates engaged in cyaniding in the outside districts, and in far away Rhodesia, where cyaniding concentrates by agitation as at the George Goch, or fine grinding by tube mills are not applicable.

If the press reports to the effect that Thomas W. Lawson of Boston is organizing a "bear raid" on copper stocks and the metal be true, that astute and somewhat spectacular operator has adopted a most unusual method in carrying out his plan. It is not customary for large operators to so openly announce their intentions concerning the market. Under existing conditions a bear raid looks somewhat like a risky proposition, though success in the stock market is largely, if not wholly, based upon the cupidity and fear of the public. These very human attributes are responsible for most of the rapid fluctuations in stock and metal prices in the markets. The eagerness with which the public sometimes buys offered stocks and other securities has an immediate effect upon the market—the demand raises the price—and the precipitate haste with which the same public endeavors to unload their holdings upon a falling market must be a matter of supreme satisfaction to the manipulators, who know the real value of the article dealt in, and who fully appreciate and take advantage of these weaknesses of the investing public. Few of that class of speculators buy for actual value of the stock, and for the dividends honestly earned and paid, but for the purpose of making quick turns, either on a rising or a falling market, for the experienced operator knows how to make money in either event; but when he publicly announces his intention to raid the market either way it is just as well to be a spectator, and not an active participant in such a campaign. It would seem that Mr. Lawson, with a full knowledge of the fact that the stock-gambling public is easily elated and as readily thrown into a panic, has some idea of engineering a campaign against copper stocks, but that he seriously contemplates attacking the metal market with a view to "pounding down" the price of copper—the metal—seems unlikely.

The New Leadville Discoveries.

When one learns of the numerous important discoveries of valuable ore bodies in the Leadville district of Colorado made within the past year, it is a matter of surprise that these discoveries had been so long delayed. It was not due to a lack of knowledge of the geology of the region nor of the possibilities which remained in untried areas, for, more than twenty years ago, the work of S. F. Emmons and of others of the United States Geological Survey, and that also of other engineers, indicated clearly the character and, to a considerable degree, the probable extent of the ore-bearing formations. Possibly the fear of encountering large volumes of water have deterred some of the mine operators of Leadville from sooner proving the unprospected areas. Several of the most important finds have been made by means of the diamond drill—and for the purpose of securing definite information at minimum cost this device is certainly superior and should be employed more than it is. From a district which was moving along in a slow and rather uncertain way, Leadville has taken on new life and is again one of the leading centers of the mining industry in Colorado. Another important factor in the revival of Leadville is the discovery of a means by which the large amount of zinc in the ores may be utilized at a profit. Old dumps and certain ore bodies, known to carry large amounts of zinc, were left untouched for years simply because they were not commercially available. The electro-magnetic separators have solved this problem, and the zinc of Leadville district now finds as ready a market as its lead or silver. That the limitations of Leadville's ore-bearing territory have been sharply defined many do not believe, and there are those who think that properly conducted prospecting in the region about Breckenridge would result in the discovery of ores similar to those at Leadville, and at the same geological horizons.

Refining Zinc Precipitates.

The following method of refining the precipitates recovered from the zinc boxes at the Homestake cyanide plant has been adopted by C. W. Merrill. It comprises a preliminary treatment with HCl, the removal of the liquid through a filter press, a subsequent treatment with H_2SO_4, the washing and drying of the precipitates, mixing with litharge, borax, silica and powdered coke, sprinkling with lead acetate, and briquetting under a pressure of from two to three tons per square inch. The briquettes are melted upon the hearth of an ordinary cupelling furnace, the resultant slag is run off, air is turned on and the Pb is cupelled in the same furnace. The resultant metal 975 to 985 fine, is run into bars. Cupel slags and bottoms are put through a blast furnace, recovering the Pb for the next cupellation, and the litharge is added to the next charge of precipitates. Mr. Merrill says that the blast furnace slags carry less than 5 dwts. to the bar; that the total cost of refining is less than .75%, and the loss, less than .1%, goes to the next precipitate. The total cost of this refining amounts to less than .75%. The loss in refining is given as less than .1%.

Books Received.

"The Delavan Lobe of the Lake Michigan Glacier of the Wisconsin Stage of Glaciation and Associated Phenomena," by W. C. Allen, Professional Paper No. 34 of the U. S. Geological Survey.

"The Structure and Genesis of the Comstock Lode," by J. A. Reid, Bulletin No. 10, Vol. 4, of the department of geology of the University of California, is a study of the ore deposits, in which the author discusses the form of the Comstock lode, the deposition of the ores and the location of the bonanzas.

Recent geological work carried on by the palæontologists of the University of California is embodied in Bulletins Nos. 7, 8 and 9, of Vol. IV, of the department of geology. These are: "New Mammalia from the Quaternary Caves of California," by Wm. J. Sinclair; "Preptoceras, a New Ungulate from the Samwel Cave, Cal.," by E. L. Furlong, and "A New Sabre-Tooth from California," by J. C. Merriam.

Obituary.

ALFRED MULHALL, assistant superintendent of the United Verde mine at Jerome, Ariz., was recently killed by an accident.

F. H. RINDGE, a mining man of Los Angeles, Cal., died at Yreka, Cal., August 29, while inspecting mines in Siskiyou county.

Personal.

NEWTON DUNYON has charge Little Bell mine at Park City, Utah.

P. S. COULDREY has resumed charge Le Roi No. 2 at Rossland, B. C.

J. F. BROAD is manager Sonora Quartz M. Co. at El Tero, Sonora, Mexico.

V. G. HILLS is making a mine examination in San Miguel county, Colorado.

L. D. SIVYER of Los Angeles, Cal., has been examining mines near Mayer, Ariz.

ARTHUR BUCKBEE has taken the management Sinker tunnel near Silver City, Idaho.

H. DUNN has been appointed superintendent Zeibright mine, east of Nevada City, Cal.

A. C. MASSEY has been appointed superintendent Richinbar M. Co. at Richinbar, Ariz.

WM. DEEM has taken the management Golden Gate mines, near Mayer, Yavapai Co., Ariz.

ROBT. LANKA has returned to southern Nevada and will examine properties near Bullfrog.

LEO VON ROSENBERG of New York City has been examining mines near Silverton, Colo.

G. B. D. TURNER, manager West Quincy mine of Park City, Utah, is making a short trip East.

WM. MAGENAU is superintendent mines and smelter for the Luna Lead Co. at Deming, N. M.

J. A. SHINN, of Denver, Colo., has returned there after an absence of ten months in Pittsburg, Pa.

S. M. MCELROY, of Pittsburg, Pa., is examining mining properties in Lake and Summit counties, Colo.

A. P. ROGERS of San Francisco, Cal., has been examining mines near Guazupares, Chihuahua, Mexico.

M. D. DRAPER has resumed the superintendency Minnesota-Connor mine, at Chloride, Mohave county, Ariz.

R. M. ATWATER, JR., of Helena, Mont., is examining the Calumet & Arizona Co.'s properties at Bisbee, Ariz.

J. K. BROWN has been elected manager Leavenworth Mountain Mining & Tunnel Co. of Georgetown, Colo.

A. L. MCEWEN, manager Imperial mine at Cable Cove, Or., is conferring with the directors at Detroit, Mich.

J. H. TALBOT has succeeded the late P. E. Murray as superintendent America M. Co. at Cananea, Sonora, Mexico.

H. H. TRAVIS has been appointed manager Banker M. Co. at Winfield, Colo., succeeding A. E. Stahler, resigned.

F. L. LARSON, superintendent El Globo mine, near Nacozari, Sonora, Mexico, has been spending his vacation in California.

R. J. DAVIDSON of Bath, N. Y., president Oregon Mines Exploration Co., has been visiting their properties at Tipton, Or.

R. G. BURNETT has been appointed manager Doornpoort Diamond Mines & Estate Co., near Pretoria, Transvaal, South Africa.

S. J. GORMLEY has been appointed superintendent Bingham Con. smelter, at Bingham, Utah, in place of W. H. Nutting, resigned.

G. L. MOATS of Salt Lake City, Utah, manager Ohio Lead Mining and Smelting Co., has been attending a directors' meeting at Dayton, Ohio.

G. W. KIMBALL of Placerville, Cal., is superintending drill prospecting for the Western Exploration & Dredging Co. in Burnt River valley, Baker county, Or.

R. E. MILLER, with Crocker-Wheeler Electric Co. in Denver, Colo., has resigned to accept a position with the Westinghouse Electric & Mfg. Co. in their Denver office.

OLIVER HARTLINE has been appointed superintendent British Columbia M. & D. Co., working mines on White Grouse mountain, 15 miles from Marysville, B. C.

JOHN H. HUDSON JR. desires to announce that his address is now with Messrs. W. R. Grace & Co., Lima, Peru, where he would be glad to hear from his friends at all times.

W. E. MITCHEL, a mining engineer of New York City, is in San Francisco, Cal., returning from an investigation of the Montreal and Boston mines at Greenwood, B. C.

JOS. C. ERMAN has taken over the management of the Live Oak C. M. Co.'s property and will hereafter be in charge of that mine as well as the Keystone mine, near Globe, Ariz.

LOUIS B. CARR, of the firm of Carr & Sauer, mining engineers and chemists, Denver, Colo., has returned there from Cyclops, Arizona, where he has been examining mining properties.

C. E. BRAINARD, late manager mining department of Fairbanks, Morse & Co., is now with the Power & Mining Machinery Company, with offices in the First National Bank Building, Chicago.

PLACER MINERS usually consider a "sluice head" for a 12-inch box set on a grade of 8 inches to 12 feet at 20 miners' inches or 30 cubic feet per minute. If five sluice heads are required it means about 150 cubic feet of water per minute.

MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

ALASKA.

It is reported that work is to be started on the Valdez, Sterling & Northern railroad, from Valdez to the Copper River mining district, by A. W. Swanitz.

ARIZONA.

Cochise County.

A concentrator is to be put in by the Cochise Con. C. Co. at Paradise. H. Alexander is manager. The company has been working the Davis group. The Ainsworth shaft on the Mascot claim is sunk at an incline of 60°.

Coconino County.

The surveyor general has approved the official survey of the Sunset lode and Sunset millsite, designated as survey No. 2118 A & B. These claims are in the Warm Springs mining district, on the strip of ground lying on the north side of the Grand Canyon of the Colorado. This is a new mining district which has been opened up in the last few years.

Gila County.

(Special Correspondence).—Work has been commenced on the Live Oak mine, near Globe, by Manager J. C. Erman and twenty tons of copper ore are being shipped daily. A leaching and electrolytic precipitating plant are to be put in.

Globe, Sept. 4.

A 25-ton experimental concentrating plant is to be put in at Globe by the Inspiration M. Co., of which J. D. Coplen is manager.

Graham County.

Superintendent F. C. Alsdorf of the Cuprite Copper Co. at Metcalf reports a good strike in the Cuprite claim 40 feet from the surface on a drift from the main shaft. A new 6 H. P. Fairbanks-Morse gasoline hoist is being set up.

Mohave County.

It is hoped to reach the 300-foot level of the Victor & Virgin mine in the San Francisco district by September 15.

The German-American M. Co. has leased the water of the Blue Ridge Co., near Vivian. The Blue Ridge people are sinking their shaft, and it will be a number of months before the mill will be run. At the German-American mines the work of sinking the shafts on three of the main veins of the group is being pushed. Considerable water is being developed, and the mill is to be started up at once.

Pinal County.

It is reported that a Chicago company has resumed work on the Lake Shore mines in the Casa Grande district.

Santa Cruz County.

The Gringo mine in Temporal gulch, 3 miles from Patagonia, has been sold to R. E. Doan of Los Angeles, who is reported as intending to put in a 50-ton mill to treat the low-grade ore.

Yavapai County.

The Crown King M. Co. is pushing work on the Crown King deep level and the Zika tunnels in the Bradshaw mountains at Crown King. The former has been surveyed to run 7000 feet west and will reach a depth of from 900 to 1800 feet. The Zika tunnel starts 1 mile west of the deep tunnel and runs north on ground of the first south extension of the Zika claim for a depth of 1500 feet and then crosscuts to the Zika and Jack Pot locations where it will form a connection with the deep level tunnel. It has been driven 500 feet. Two 15 by 16 Rand compressors have been ordered. Pending their arrival the work will be driven by hand.——The El Dorado G. M. Co., in Copper basin, west of Prescott, has its working shaft down 200 feet.

Yuma County.

The owners of the Valenxuela mines, 15 miles northwest of Quartzsite, have struck water in the well that they have been boring. The company has the machinery on the ground for a 10-ton smelter and has only been waiting for the discovery of water before setting it up and beginning work.

CALIFORNIA.

Amador County.

The Zeila's new hoist is in operation and the mill has resumed crushing. They are putting in an air compressor to be run by electric power. They will operate machine drills.

Butte County.

J. M. McClung has taken the blue lead mine near Bangor, and is pumping out the water and getting the mine in shape so gravel can be taken out. A. Duggins has charge.

Calaveras County.

The Calaveras Prospect publishes the following list of mines, together with the names of the local superintendents and foremen; Yellow Boy M. Co., C. V. Zinn, J. A. Campbell, Murphys; Chispa M. Co., F. A. Mitchler, Murphys; Ozark M. Co., F. A. Mitchler, Murphys; Othello M. Co., John M. Shepherd, Murphys; Cordellia M. Co., W. L. Driver, Murphys; Hercules M. Co., L. L. Washburn, Murphys; Clary G. M. Co., W. H. Clary, Sheep Ranch; Big Horn mine, J. E. Spencer. Murphys; Big Trees M. Co., G. O. Pearce, Murphys; "49" M. Co., J. M. Evans, Douglas Flat; Bourbon M. Co., W. H. Tulloch, Murphys; Black mining claim, E. Black, Murphys; Carley Bros. mining claims, S. O. Carley, Murphys; May Day M. Co., John Bunney, Murphys; Stonewall and Hidden Treasure mines, Geo. Taylor, Murphys; Caruthers mine, Jeff Raggio, Sheep Ranch; Lucky Strike mine, Northwood Barrow, Murphys; Alhambra mine, John Ross, Murphys; Sonoma mine, Sierra Nevada D. Co., San Francisco.

El Dorado County.

A new hoist has been put on the Clipper mine above Georgetown.——F. Hall of San Francisco has bonded the Marco Varozza property near Smith Flat.——It is reported that a 20-stamp mill will be put on the mine in Coloma canyon which is being operated under the supervision of S. Beers of Butte, Mont.

Mariposa County.

W. Graham of Los Angeles has bonded the Dexter mines, 6 miles east of Coulterville. Harry Argaul has charge of pumping out the water.——The Austin mill at Whitlock has started crushing.——At the Teats mine in Whitlock, J. Nevills, E. Donovan and S. Hogan are mining, and as soon as enough ore is taken out the Teats mill will be started.——The Schroeder Bros. of Saxon's Creek, near Whitlock, intend building a mill on their property.

Nevada County.

The new 10-stamp mill at the Oustomah mine, near Nevada City, was destroyed by fire September 1, a loss of $12,000, on which there is an insurance of $4000.——The pumps have been started at the Banner mine on Banner mountain, near Nevada City. Pipe has been laid for a water supply and a shaft will be sunk to the 1200-foot level. C. M. Belshaw and E. C. Voorheis are interested.

Under the direction of Superintendent J. H. English of the Spanish Ridge mine, in the Washington district, concentrators purchased from the Gold Tunnel mine are to be put in.

Plumas County.

The Plumas-Eureka mine on Eureka peak, near Johnsville, has passed under the control of J. D. Johnston and associates of Newport, R. I., who intend to run a 6000-foot double-track tunnel at a lower level than the old workings. It is reported that a new stamp mill and cyanide plant are to be put up at the mouth of the tunnel.

Shasta County.

Another furnace will be put in the Afterthought smelter at Ingot.

Sierra County.

At Pike City, G. W. Mohler will work the Nobby placer mine this fall and winter.——C. C. Weisenburger is repairing the 10-stamp mill at the Rainbow mine, between Alleghany and Chipps Flat.——As a result of an examination of the Poker Flat quartz mine, near Table Rock, by Jos. Voyle, it is reported that F. P. Roddy will put in a cyanide plant.

Tulare County.

The Josephine mine at White River is putting in a roller mill and other machinery to crush their ore.

Tuolumne County.

A new rock breaker has been put in at the Los Angeles mine, near Sonora, being worked by J. Phillips.——George Stayton is sinking a 3-compartment shaft on his claim, near Jacksonville.

Superintendent Partington has fifteen stamps dropping at the Longfellow mill at Big Oak Flat.——The water company has given notice that the supply will have been exhausted by Sept. 10. Many mines will close as a consequence, and mills will be given a general overhauling and put in condition for a long run when the wet weather sets in.——The New Lead mine, near Phœnix lake, east of Sonora, owned by M. Bottini, has been bonded to H. J. Dykes. The property has been developed to a depth of 120 feet, drifts being run 60 feet east and west on the 100-foot level. A new incline shaft will be put down, and the property will be equipped with a 10-stamp mill.——A company has been organized to work the Columbia mine, situated near Columbia on Experimental gulch, by W. G. Phipps and A. Baier of Columbia, F. Littlehall of San Francisco, and G. B. Morow of Sonora.

COLORADO.

Chaffee County.

Platinum in paying quantities has been discovered near Buena Vista by W. G. Zeigler. In a sample submitted to the United States Geological Survey a chemist found gold, 1.99 ounce per ton; platinum, 0.43 ounce per ton. The samples submitted were taken from claims 2 miles up the Arkansas river.

Clear Creek County.

The Topeka group, in East Argentine, owned by E. Erickson, has been bonded to Eastern parties, who are developing it.——Thomas Rodda of Idaho Springs has secured a bond and lease on the Waukegan from Frank McCready, and is making arrangements to carry on development work during the winter. The Waukegan is near Loveland pass.——The Blue Bird claims, on Republican mountain, have been leased and bonded by D. W. Stewart of Idaho Springs. The property is owned by Wm. Hunt of Georgetown and Nels Frohm of Denver. A crosscut tunnel which has been driven 800 feet will be continued.——The Silver Plume M. Co., with Edward Butts of Chicago as president, has taken an option on the Aspen-Promise group, on Leavenworth mountain, near Silver Plume, and is prepared to carry on development. —— On Republican mountain, near Georgetown, the Joplin tunnel is being driven by the Joplin Tunneling G. & S. M. Co. to develop the Gambetta group. Of the 800 feet to be driven, over 100 feet have been run. B. J. O'Connell of Georgetown is superintendent.— R. C. Bonney, manager of the Sun and Moon mines, has purchased for his company twenty-one mining claims in Pleasant Valley district. This group adjoins the Sun and Moon holdings and will be developed by a lateral, which is now being driven on the Sun and Moon, from the Newhouse tunnel. Bonney's lateral has been run easterly for 1200 feet and is rapidly draining the mountain.——Walter Farragher has started operations on the Queen of the West, in the East Argentine district, recently secured under lease by Thomas Cunningham of Georgetown.

Custer County.

It is claimed that the continuation of the Bassick contact has been struck in a 100-foot crosscut from the Vulcan tunnel of the Walcott G. M. Co., near Silver Cliff. The existence of the Bassick contact has long been disputed. The tunnel is to be continued under the old shaft, giving a depth of 500 feet. The company intends building a mill on the east side of Tyndall mountain.

Eagle County.

Rich gold strikes have been made 18 miles southeast of Eagle by James Murphy and H. W. Ennen and R. B. Davis. They have a lease on the Lucy mine, where the strike was made. The ore is found in the granite 500 feet below the quartzite. It carries oxidized iron sprinkled with free gold.

Gilpin County.

The Powers mine, in lower Russell district, has shipped enargite to the Denver smelters. The second-class ores are shipped to the concentrating works. Increased shipments of this class will be made from the 200-foot east workings to the old workings, which will improve the ventilation, after which the working force will be increased and regular shipments will follow.——The Benzie Investment Co. announces that it will resume operations on the Ingalls property, on Gunnell hill, near Central City, and that a large plant of machinery will be put in.——G. W. Mabeet, Sr., and other Denver parties are arranging for the resumption of work on the Virginia property, up Chase gulch, near Central City.

Work has been resumed on the Polaris group on Colorado hill, in the Pine Creek district, by J. A. Peterson of Idaho Springs and J. L. Walters of Apex. The main shaft on the Polaris is 70 feet deep and is to be unwatered and retimbered and arrangements are being made to sink it deeper.——The Sherman & Macon M. & M. Co. is developing its claims on Silver creek, near Apex, with a tunnel which has been driven 600 feet and is to be extended 400 feet farther. Charles Sperry is in charge.——The Pet shaft of the Golden Rod M. & M. Co., near the head of Silver creek, is down over 200 feet and is to be unwatered by a crosscut tunnel being driven to tap it.——The Pine Creek G. M. & M. Co. is unwatering its Bonanza shaft on Oregon mountain, near Apex, with W. S. Barrick in charge. The shaft is down about 70 feet, and as soon as the water is out they will timber and continue sinking. The Pine Creek Co. is building a shafthouse on its Rochester shaft, with the intention of putting in machinery. This shaft is down 65 feet and the company intends to sink it to the 100-foot point and then drift and crosscut to open up the ore body.——At the property of the Evergreen G. & C. M. Co., Superintendent J. L. Walters has been grading for a new road and a new shaft building to be put up east of the main tunnel. The new shaft building is to be 30x60 feet in dimensions and the equipment will consist of a 30 H. P. hoisting engine, 80 H. P. boiler and a Cornish pump. The shaft on which this plant is to be put in is down 75 feet and is to be continued several hundred feet, so as to get below the ore bodies of the Evergreen property, which have already been opened up in the tunnel and other shaft workings. The main tunnel is in 485 feet, while the other tunnel is in 215 feet.——The Wheeler mill on North Clear creek has been leased by H. B. Gilbert & Sons for the treatment of ores from their lease on the Star of Gilpin mine in Russell district.——In the shaft of the Homestake mine in Russell district sinking operations are being carried on at a depth of 330 feet. Stoping in the 300 west level is developing a high-grade concentrating material in sight, from which shipments are being made.——A new shaft building 28x50 feet has been built on the Ralls County mine on Quartz hill, Nevada district, and an 8½x10 hoist and 50 H. P. boiler have been put on. The main shaft is down 700 feet. The shaft has been repaired in good shape down to the 300-foot level, at which point work for the present will be carried on, the intention being to repair the balance of the shaft at a later date.

Gunnison County.

The Belzora-Bassick M. & D. Co. plans to drive a 2700-foot crosscut tunnel into Sacramento mountain, near Pitkin. This is intended to cut the Sacramento, Monte Vista and Lillie Dell veins.——The Taylor Park M. Co. is building a 100-ton cyanide plant to treat the output of the Enterprise mine in Tellurium gulch, near Tin Cup.

The vein in the Camp Bird shaft, near Bowerman, is improving with depth. The shaft is 130 feet. The mill has completed the treatment of 500 tons of ore. A test is being made on seventy-five tons by cyanide at the Quartz Creek mill at Pitkin.——Adjoining the Camp Bird, the Netted Gem M. Co. is sinking a shaft and driving a tunnel.

Work is being pushed on the mill being built by the Raymond Consolidated Mines Co. on Ohio creek, near Pitkin. They expect to have it finished by November 15.——Wm. Friend, operating the Grand Prize group, near Pitkin, will start a new level at a depth of 106 feet.

Lake County.

(Special Correspondence).—J. A. Shinn, who has been in Pittsburg the past ten months, endeavoring to interest capital in his mining and railroad enterprise, has returned to Leadville with S. M. McElroy, who is interested in the enterprise, and it is believed the big tunnel will be cut through the hill from Empire gulch, on the Leadville side, to Four Mile, on the Fairplay side of the mountain. This tunnel will open up some undeveloped country and will be used as a transportation as well as a mining tunnel. It is understood that the Westinghouse Electric & Manufacturing Co. of Pittsburg has interested itself in the enterprise and will back the railroad end of the scheme. If the railroad is built it will connect with the Colorado & Southern at Fairplay and run through to Leadville.

Leadville, Sept. 2.

The lower section of the ore channels between the Penrose and the Coronado is to be thoroughly explored, as the pump station at the bottom of the Penrose shaft, 100 feet long by 16 feet high and 60 feet wide, is completed. Two large compound and one triple expansion pumps are being set, with a combined capacity of 2500 gallons per minute. When the pumps are working smoothly the 1200-foot drift to the Coronado will be

driven as quickly as possible. When the drift reaches the Coronado it will be 100 feet below the bottom of the shaft, which will be sunk to the level of the drift to make connections. When the connections are made the Coronado ground will be drained. Little water will be lifted from this shaft, as it will be handled at the Penrose. The Sixth Street shaft is the half way mark between the two properties, and from the upper levels of this property large quantities of iron have been shipped, but below the 600-foot point no work has been done. The Penrose drift will cut under the shaft 300 feet, and it is the general belief that the same ore shoot found in the Coronado will be exposed in the Sixth Street shaft. By the driving of the drift the downtown section will be drained.——At the Mammoth placer, in Big Evans gulch, the drill hole discloses two bodies of ore, one at the 450-foot level and the other at 600 feet. The shaft is down 400 feet and making good progress, and the water so far has not impeded sinking.

In Iowa gulch, near Leadville, the Ella Beeler has driven a tunnel in 600 feet and rails are being laid to the breast, and the ore body that was recently opened will be thoroughly prospected.——The Doris is shipping iron and manganese, also some carbonates that were recently opened.——The Ready Cash from the breast of the tunnel, 400 feet, is shipping a good grade of ore.——A new tunnel has been started on the North Star and will be driven 500 feet.——The Auroras Nos. 1 and 2 are to be opened up by a tunnel driven from the Ready Cash.—— The Moyer from both shafts is shipping 1300 tons per month of iron, copper, lead and zinc. All of the surface improvements, including new boilers and hoisting plant, have been put in at the Tucson, a continuation of the Moyer shoot to the east, preparatory to sinking the shaft another lift of 350 feet. When this is completed the shaft will be 950 feet deep and under the ore shoot.

Sinking has been started from the 400-foot level of the Silver Chord winze in the Yak tunnel. This is a shaft 4x8 feet and equipped with hoist and pumps, and will be sunk 200 feet farther.——The 420 foot level of the Ballard shaft at Leadville has been reached. The shaft is to be enlarged to 4x9 in the clear and retimbered to the bottom.——Lomeister & Lynch have leased the Little Nell on Carbonate hill, Leadville, and resumed drifting from the bottom of the shaft, a depth of 500 feet. They hope to catch the Doddridge ore shoot.

Work has been resumed with two shifts on the Mt. Elbert property, 2 miles west of Twin Lakes.——The Manhattan M. &. M. and the Mt. Elbert T. & M. Cos. have resumed work, and arrangements have been concluded by which the Twin Lakes G. M. Co. has turned over, under lease, their mining property on Mt. Elbert to Chas. J. Fox, et al.

Ouray County.

The Atlas M. & M. Co. are making a test of the ore produced from their property near Ouray, having leased the Governor mill and put in electric power. President J. P. Sidwell is at the mine.

San Juan County.

(Special Correspondence).—Three years ago the operators and miners in San Juan county made an agreement which was satisfactory to both sides. This agreement expired on Sept. 1, and there is some rumor of there being trouble in the camps surrounding Silverton, but the more conservative element on both sides does not anticipate any serious difficulty, and it is believed and hoped that an adjustment of all differences can be made without a clash. During the big strike last year in other camps the agreement in the Silverton district between the operators and miners avoided a strike. It has been intimated by some that there will be no agreement signed this year. The following is the scale submitted by the Mine Owners' Association: Battery--Huntington and Chilian millmen, $3.50 for eight hours or $4 for twelve hours. Jig Men—One to five single jigs, without helpers, $3.25 for eight hours or $3.75 for twelve hours. Jig Men—More than five single jigs, without helpers, $3.50 for eight hours or $3.75 for twelve hours. Table Men—$3.25 for eight hours or $3.75 for twelve hours. Vanner Men—$3.50 for eight hours or $4 for twelve hours. Canvas Plant—$3 for eight hours or $3.25 for twelve hours. Engineers—$3.50 for eight hours or $4 for twelve hours. Firemen—$3 for eight hours or $3.30 for twelve hours. Crusher Men—$3.25 for ten hours or $3.75 for twelve hours. Blacksmiths—$4 for ten hours. Blacksmiths' helpers—$3.25 for ten hours. Roustabouts—$3 for ten hours.

Silverton, Sept. 4.

The tunnel at the Auburn claims, near Middleton, northeast of Silverton, has been driven over 450 feet, under the direction of A. V. Shaw. Progress is to be increased in speed when arrangements have been made to handle the water.——The new Hamlet mill at Middleton is handling from fifty to sixty tons of ore daily and an average of three carloads of concentrates are being shipped to the smelter each week. Canvas tables are to be put in.——O. Brendle, of the Bullion Bar M. Co., is working properties in Maggie gulch, near Silverton, and is making preparations to put in a compressor and air drills.——The Highland Mary mine, near Silverton, is being operated by the Gold Tunnel & Railway Co., under the supervision of W. D. Cole.

At the Galty Boy claims, in Dry gulch, north of Silverton, the work is being done by the Ross M. Co. A 600-foot crosscut tunnel has been run, 700 feet of drifting has been finished and a 200-foot upraise is being made. A 6-drill air compressor is to be put in.

T. J. Hurley, manager of the Ruby Basin M. Co., and the Natalie-Occidental Co. of Silverton, has bought machinery for water power and electric plant to run the Ruby concentrator mill and operate the Ruby mine by electricity. The Ruby mill treats from sixty to sixty-five tons of ore from the mine daily, making from fourteen to fifteen tons of concentrates, carrying on an average 50% lead containing silver and gold values. He states that he is driving work in the Natalie-Occidental and will probably construct a large mill on these properties another season, as well as enlarge the mill of the Ruby Basin Co.

The Silver Ledge mine, near Chattanooga, is shipping zinc concentrated by magnetic separators. Carmichael & Kramer of Silverton are working the mine. The mill is equipped with water power, and operations have to be suspended each season on account of the freezing up of the water supply pipes. The Ledge management is endeavoring to have the electric company extend its line from Red Mountain to Chattanooga and supply the Ledge mill with electricity.

San Miguel County.

The greater part of the Smuggler-Union mines at Telluride has been leased by the owning company to J. H. Robeson of Denver and E. J. Carter, the present superintendent of the property, for a term of years. Their leasehold comprises all of the territory lying between the Bullion tunnel and the third level, a block of ground 600 feet high by several thousand feet in length, including the New Pandora mill of 60 stamps. The new operators will require 200 men for the mine and mill.

Summit County.

G. C. Smith of Breckenridge is opening up good lead and silver ore in the Charlie Ross property, at the head of McCullough gulch.

At this time of the year most of the high-bar placer mines in this county are running at half speed on account of shortage of water. To obviate this difficulty, G. L. Kingsbury, manager of the Banner Placer G. M. Co., had several artificial ponds constructed 3500 feet west of and 200 feet above the placer pit. These small lakes fill during the night and next day there is an abundant supply for the two hydraulic giants. A small self-acting boom reservoir at the head of the pit fills and discharges itself every few minutes during the day and night. This "booming" sweeps everything before it down to the bedrock or hardpan to the "wings" of the first sluice, where the stream is contracted, and the material is forced through the 4-foot wide sluiceway, the bottom of which is lined with angle-bar steel riffles. An undercurrent separates the black sand from the balance of the waste and delivers it to the concentrating shed, where concentrating tables reduce the bulk of the sand to a grade of concentrates suitable for smelting. The tables are driven by electricity generated by a water wheel.

At the Jessie mine near Breckenridge 20 stamps are running on good ore from the upper and lower tunnel workings. —— The main crosscut tunnel of the Mary Verna mine at Frisco is in 240 feet. —— D. W. Fall is working a lease on the Maggie May and J. K. & F. properties on Gibson hill. A shaft is sunk. —— The North American mines' main tunnel at Curtin is in over 240 feet ——At the Novelty group near Breckenridge, now owned by J. G. Detwiler and the Summit County Mining Exchange, a horse whim is being put in and a shaft house put up. They intend to sink the main shaft 100 feet deep and then commence taking out ore for shipment, continuing to sink at the same time.

Teller County.

The output of Cripple Creek mines for August was as follows:

Plant.	Tons.	Av. Value.	Value.
Smelters	10,000	$60 00	$ 600,000
Portland	7,500	29 00	217,500
U. S. R. & R.	25,000	30 00	750,000
Economic	7,500	30 00	225,000
Dorcas	3,500	33 00	115,500
Wild Horse	1,500	4 50	6,975
Anaconda	2,000	5 00	10,000
Sioux Falls	1,550	2 00	3,100
Totals	58,600		$1,928,075

Sinking has been resumed from the 270-foot level of the Modoc mine on Bull hill, near Cripple Creek, by Manager F. H. Frankenberg. The shaft has three compartments and is to be sunk to a depth of 1000 feet.

Carrington & Eby, lessees of the Silver Belle & Mohawk Belle properties on Raven hill near Cripple Creek, are putting in crushers and rolls with a capacity of twenty tons to crush the ore before amalgamation.—— The hoist of the Last Dollar mine on Bull hill has been repaired and work resumed.——R. P. Russell has obtained a three-years' lease on the Cardinal on a southwest spur of Gold hill.——Water has caused Hansbrough and associates to stop work in the lower levels of the Morning Star claim of the Acacia. Work is being done on the 400-foot level until the water subsides. The Morning Star has a 400-foot shaft, and 170 feet from the shaft a winze has been sunk 250 feet, or to a total depth of 650 feet. It is proposed to continue the winze for 100 feet.

High-grade gold ore is said to have been opened up at a depth of 100 feet in the Agnes property, on Beacon hill, near Cripple Creek. Therson Bros. are developing the vein.——A five-year lease has been taken on the Red Rock and the Iron King lode claims of the Colorado City & Manitou Co., on the saddle between Ironclad and Tenderfoot hills. A 15-ton daily cyanide plant will be put in for trial purposes.——At the Home claim of the Cedar Hill G. M. Co., on Ironclad hill, Gardner, Jones & Co. are preparing to unwater the shaft and resume sinking to the 200-foot point.

IDAHO.

Blaine County.

The upraise at the Hillside mine near Bellevue has been finished and sinking is being continued in the shaft. The new works are showing good galena ore. A boiler, engine and hoist are to be put in.

Boise County.

A cyanide plant is planned to treat the ore from the Red Jacket ledge of the Equitable Co., in the Black district, near Boise.——Manager J. J. Overbillig of the Twentieth Century Co. is working day and night shifts drifting for the main ledge.——J. W. Edgerton intends developing the Nelson property, in the Black Hornet district, near Boise, recently taken over by the Conservative Development Co. He intends putting up a reduction mill.

Elmore County.

The 10-stamp experimental mill at the Tahoma mine at Atlanta is said to have proven a success, and twenty stamps are to be added to the mill, which will first amalgamate and then concentrate and cyanide the ore.

Idaho County.

It is reported that the Penn-Idaho G. M. Co. of Boise has filed articles of incorporation and will acquire mining property near Big creek formerly owned by D. T. Davis. Development work is to be pushed to determine the proper reduction process adapted to the treatment of the ore, and a mill will be built next summer. The property will be managed by J. B. Eldredge, who is also manager of the Independence.——At the Twentieth Century property, near Roosevelt, preparations are being made for continuous development through fall and winter. Dynamos and electric fixtures with capacity of 700 lights and the stamp mill machinery are being put up. The cable for the aerial tramway from the main working tunnel, Toltac No. 3, to the mill has arrived. The Toltac No. 3 tunnel is in 600 feet.

Nez Perces County.

The Lewiston-Clarkston Co. is preparing to run a high-power line up the Snake river, 25 miles above Lewiston, to furnish power to mining properties and the G. H. Kester marble quarries. Negotiations for the first power have been opened by J. M. Edwards, president of the Gold Crown Co., the Eastern stockholders of which have decided to start with a stamp mill with a capacity of 10 tons per day.

MICHIGAN.

Houghton County.

The Champion's experimental crushing mill at Freda is designed to test the efficiency and economy of rock crushing as against rock stamping. For the test in economy each unit of the machinery is to be driven by an independent individual electric motor. An individual meter will be attached to each of these motors, by which the electric consumption may be measured at each unit. For the test in efficiency the principles of the crushing system are such that samples will show exactly what copper is being recovered, what non-productive pulp is being discharged and what copper is being lost at each stage of the work. The rock for this plant will be crushed in the rockhouse at the mine in crushers which will have a maximum opening of 4 inches and a minimum opening of 3 inches. The rock at the mill will feed from the bins to a shaking grizzly, and in this process the barrel copper will be picked out. The bars in the grizzly screen will each have a face of 2½ inches, with spaces between of 1½ inch. All material above 1½ inch will feed to a gyratory crusher, whose jaws will have an opening of approximately 1½ inch, thus bringing the product uniformly to that maximum size. The entire product will then be sized in a series of cylindrical revolving screens, graded to sizes varying in stages of ¼ inch, and all copper released by the crushing in the gyratory will be extracted in this process. The sized material will then be crushed in stages of ½ inch and the released copper extracted and automatically discharged, while material not containing copper in commercial quantity will be discharged at each stage. The first stage of crushing after the rock leaves the gyratory will be in the Anaconda type of rolls, with heavy springs on the axis, so that any chunks of copper feeding to it may be allowed to pass through without obstructing the work. After this initial crushing in rolls, the various stages will have rolls with rigid axes.

The Tecumseh will have two shafts under way this fall. The first of these has been started. The second will follow the diamond-drill exploration to be undertaken, 1000 feet southwest of the first location.

The annual report of the Wolverine mine at Kearsarge shows that there were hoisted from the various shafts of the mine 336,780 tons of rock as against 328,412 tons hoisted for the preceding year, a gain of 8368 tons, despite an interruption of two weeks by reason of a strike of the trammers. Of this rock 321,813 tons were stamped, making a discard of only 14,967 tons. The mineral return for 1905 was 11,982,345 pounds, against 12,152,690 pounds for the year preceding, while the product of copper was 9,729,971 pounds, against 9,300,695 pounds for the preceding year. The cost per ton of rock hoisted was $1.47 a ton, against $1.50 a ton last year, a saving of 3 cents a ton. This presents the apparent anomaly of greater depth and decreasing cost. The cost per ton of rock stamped shows no change from 1904, the charge being $1.51 a ton. The cost of the refined copper laid down at the mine was 5.098 cents, as against 5.329 cents last year, a saving of .231 of a cent a pound. The total cost per pound of the copper laid down in New York figures to 6.222 cents a pound, the cost of smelting, freight and marketing charges with those of the New York market being 1.124 cent a pound. The total cost of copper last year was 6.458 cents a pound, being .236 of a cent more than the price for which the finished product was obtained this year.

The Calumet & Hecla struck the Kearsarge lode, containing good copper, at No. 21 location, within 200 feet of the Osceola boundary. It has been searching at this location for the past two years. The lode was cut at a depth of about 100 feet.

At the plant of the Michigan Smelting Co. in West Houghton, in the regular course of work, there was taken from one refining furnace working on Copper Range Consolidated output 292,000 pounds of refined copper, cast in ingot bars, in 7 hours. During the process there was an interruption of half an hour, so that the actual time of casting was 6½ hours. This work was done at the rate of 750 pounds of copper every minute. In operating the furnace and casting machinery 6 men were employed, while 4 men were loading the copper as the finished ingots were delivered to the loading platform from the conveyor.

MISSOURI.

The district output of zinc ore for the first eight months of 1905 has been 323,842,350 pounds, as against a production of 345,145,670 pounds during the corresponding period of 1904. The ore brought $7,272,750 as against $5,724,185 in 1904. The lead output since January 1 has been 39,829,720 pounds, which sold for $1,166,130. During the same time last year the output was 43,769,160 pounds, which sold for $1,193,420; a decrease of 3,939,440 pounds in production and $27,290 in value. The total for both ores for the first eight months of the year is $8,448,780

against a total value of $6,917,600 for the corresponding months of 1904; an increase of $1,531,180.

MONTANA.

The mine owners and miners of Montana have reached an agreement on the wage scale for the coming year. The new schedule is to continue until Oct. 1, 1906. The wages for skillful men range from $3.60 down to $3 a day for underground work; for outside work they are from $4 down to $2.50. Five holidays are mentioned.

Broadwater County.

The concentrator on the East Pacific at Winston has been started and runs successfully. There are 20,000 tons of concentrating ore on the dumps, besides large bodies of concentrating ores in the mines which are blocked out. A cyanide plant may be added.

Fergus County.

Prospecting is to be started with a diamond dril on the Fergus-Hilger land on Dog creek, northeast of Kendall. A. S. Wright, W. H. Fergus, H. M. Rae and David Hilger are interested in the company. —— The mill at the Gold Reef mine at Gilt Edge has been temporarily closed until the cyanide plant is finished. L. U. Loomis is manager.

Granite County.

Rich silver ore is being opened up in the Fraction lode of the Hope mine at Philipsburg. J. R. Lucas is superintendent.

Jefferson County.

It is reported that John Rothfuss intends putting up a 100-ton concentrator at the Jacquemin properties in the Elkhorn district. He has been making large shipments to the East Helena smelter.

Lewis and Clarke County.

The Bald Butte Co. mines, 4 miles from Marysville, are in charge of L. S. Ropes. R. M. Awater of Helena is consulting engineer. Twenty of the forty stamps in the mill are dropping on the company ore, two shifts each day, and eight of the sixteen concentrating tables are running. About 2000 feet from the entrance to the lower tunnel a shaft has been sunk 400 feet, giving the company a depth of 1000 feet. Crosscutting for the veins from the bottom is now in progress. There are two veins, the Albion and the Genesee. All the drilling is done by hand. The company is impounding the tailings from the mill. It is employing forty-one men, thirty-six of whom are in the mines.

Madison County.

The new 5-stamp mill at the Tesla mine near Pony has been started under the direction of C. E. Beebe.

Missoula County.

(Special Correspondence).—The Amador M. Co., which is building a railroad 12 miles long from the town of Amador to the mines, expects to have the line completed soon. The road will be equipped by the Northern Pacific Railroad Co., and as soon as the road is finished the Amador expects to begin shipping ore to Butte for treatment at the rate of 100 tons a day to start with.

Missoula, Sept. 3.

Silver Bow County.

(Special Correspondence).—F. A. Heinze of the United Copper Co. is operating a copper property on Knight island in Prince William sound. ——The United Copper mines in the Butte district have increased their output. The Corra mine has been raised from 300 to 600 tons of ore per day, and the Belmont, one on which Heinze spent $200,000 in development work, now yields 100 tons a day. Ore bins are being built at the Belmont, and as soon as completed the output will be more than doubled.——The North Butte M. Co. has taken up the bond on the Miners' Union claim, adjoining the Speculator, and has purchased the outstanding interests. The North Butte now owns the Miners' Union, Jessie, Edith May and the Speculator. The company is producing 800 tons of ore daily, and has a long-time contract with the Washoe for the treatment of its ores. The North Butte will sink an additional shaft in order to increase the output. Any funds necessary for sinking the new shaft will be provided from the earnings.——The by-products of silver and gold in the copper ores of the Anaconda Co. amount to $3,000,000 annually. Last year the company produced more than 100,000,000 pounds of copper, 4,000,000 ounces of silver and $300,000 worth of gold. This year the copper production of the company will be 115,000,000 pounds.

Butte, Sept. 4.

Hoisting has been resumed at the Neversweat mine of the Amalgamated at Butte, after a month of shaft retimbering.——The Pittsburg & Montana Co. is making matte and shipping it to the smelter of the Montana Ore Purchasing Co., where it is being treated in the blast furnace. The matte carries a copper product of 15%. The Pittsburg Co. did not intend to attempt to operate any of its furnaces until the arrival of its new blower, bought from the Mountain Copper Co. of Keswick, Cal., a short time ago, but its ore bins were overflowing and it had no place to put the output of its mines except on the ground, which would necessitate handling it over again.——The hoisting engine bought by the Reins C. Co. for the Combination mine is working. The shaft will be deepened 400 feet, which will give it a total depth of 1200 feet, after which the veins will be crosscut and mining of ore resumed. The company has two pumps at the 800-foot station, each of which will throw 700 gallons of water 800 feet per minute, and will use other pumps while sinking. The upraise started from the 800 to the surface, 40 or 50 feet north of the shaft, has broken into the opening on the 600 and will be continued upward.——At the property of the Raven Co., north of Butte, development work by way of the 1200-foot station of the Buffalo is progressing rapidly.

The Little Annie mine, west of the Goldsmith No. 2, northwest of Walkerville, has been sold to the Cobban Realty Co. of Butte. The mine was owned by C. Ramsdell of Deer Lodge.

NEVADA.

Lincoln County.

W. H. Bainbridge, superintendent of Ascott M. & M. Co., intends resuming work on the Ascott mine, near Searchlight, during September.——The Wallace G. M. Co. is to resume work at its claims at Capitol Camp, 7 miles southeast of Nelson, under the direction of D. Catlin.——The Quartette shaft at Searchlight is 40 feet below the ninth level and is to be continued to a depth of 1000 feet. Drifting has been started on the ninth and is being continued on the seventh levels.——It is reported that a 10-stamp mill and cyanide plant is to be put up at the Cyrus Noble mine, at Searchlight, by Manager J. J. Prendergast.——Sinking has been begun on the Commonwealth mine, near Searchlight.

White Pine County.

(Special Correspondence).—An organization of Butte, Mont., mining men has secured twenty claims near Ely close to the property of the Giroux & Nevada M. Co. and has organized the Butte & Ely Copper Co.

Ely, Sept. 4.

NEW MEXICO.

Grant County.

L. P. Deming is sinking a new shaft on the Pacific mine at Pinos Altos to provide better air. The shaft will be sunk to a depth of 400 feet and is down 150 feet. —— The Colorado Fuel & Iron Co. is again working a large force on its iron mines at Fierro.

Sierra County.

Work is to be resumed on the Wicks mine, near Hillsboro.——The owners of the Snake mine, near Hillsboro, have let a contract for 100,000 feet of lumber and work will soon be commenced on a 50-ton reduction plant.

Socorro County.

In the Key mine, in the Magdalena mountains, near Kelly, owned by the Mine Dev. Co., at a depth of 400 feet, while making a crosscut east from what was supposed to be the footwall of the ore, high-grade lead carbonate has been found by C. T. Brown.

OREGON.

Douglas County.

The Oregon Securities Co., at Bohemia, has completed arrangements for building an aerial tram from near the summit of the ridge between City creek and Champion basin to the Musick mine. This plan of equipment was decided on by Superintendent Archer when he took charge of the property, instead of continuing the crosscut through the ridge, and then building a surface tram from the City creek portal to the Musick. Under the new arrangement ore mined at the Musick will be loaded on the aerial tram, transported about 3000 feet and will be delivered into a bin over an upraise made from the lower Champion tunnel level, which will discharge by gravity into a receiving bin 500 feet beneath. From this bin ore will be loaded into the cars operated by the surface tram, drawn 1000 feet through the crosscut tunnel and then 3600 feet down the incline to the 30-stamp mill. Champion ores which are being mined on the crosscut level will be loaded direct into the cars that are moved by the surface tram. The crosscut, which has been driven 1000 feet into the mountain, is 10x10 feet in the clear, has room for a double track and will accommodate the large electric motor put in by the company for traction work on this level. At the Oregon Securities mill twenty stamps have been dropping this summer on Champion ore.——A rich placer strike is reported on Twelve-Mile creek, in the western part of this county. This new placer find is said not only to comprise the creek bed, but also its banks and even the high ground bordering thereon. This new discovery is in the Salmon mountain, Johnson creek and Sixes mining belt in the Coast Range mountains.——At the last meeting of the Bohemia Mine Owners' Association, F. J. Hard, A. Y. Churchill and Frank McIntyre were chosen a committee to investigate the possibilities of having a smelting plant built in the district.

Grant County.

The Sheridan shaft, near Granite, has been unwatered and sinking and drifting has been started.

Josephine County.

A 3-stamp mill and water power plant is being put in at the Gold Pick mill on Bolen creek, near Holland, by Manager Frank Fowler.

Lane County.

At the Great Northern mine, in the Blue River mining district, the aerial tram recently put in is a success. Within the past few months a new mill and bunkhouse have been built by Manager C. L. Inman.

Malheur County.

Reports from the Mormon Basin district state that the Summit mill, under the management of P. G. Wells, is operating steadily; the output is so satisfactory that at a recent meeting of the owners it was decided to increase the capacity of the mill to forty stamps. At the Gold Coin group the hoist has been completed and the reduction plant is ready for operation.

UTAH.

Beaver County.

The Peck concentrator, which, after a long series of experiments has been found suitable to work at a profit the dump of the Horn Silver mine of Frisco, has begun its regular run, and the management expects to put through from now on not less than 200 tons daily.—— Superintendent Gott of the Skylark Copper Co., operating at Blue Acre, in the Beaver Lake district, in his report to Manager McMullen of Salt Lake for August, says that the shaft now being sunk is down 124 feet and the bottom is in ore. The vein is on a contact of limestone and granite and carries values in copper, lead, silver and gold.

Juab County.

Ground has been broken on the Tetro property at Eureka preparatory to sinking the new shaft 400 feet to the east of the entrance to the old tunnel. A shaft with a single compartment and manway will be sunk 700 feet.

A station is being cut at the 400-foot level of the May Day mine, at Eureka.

Piute County.

It is reported that telluride ore is being taken from the incline shaft of Wm. Robottom's mine, near Junction City. The shaft is down 90 feet.

Salt Lake County.

The Bingham Mary M. Co. has been formed to work the Commonwealth and Mary claims of Bingham. S. Bamberger of Salt Lake City is president and J. H. Bean secretary. An electric hoist is to be put in and shaft sinking started.

The Uintah, M., M. & D. Co. has bought the Castro group at Bingham from N. Castro. Manager L. C. Moore will continue the tunnel, which has been driven 700 feet.

Sevier County.

The Mt. Baldy M. Co., operating in the Gold Mountain district, near Richfield, is driving a main working tunnel which will tap the vein at a depth of 500 feet. C. W. Watts is president.

Shoshone County.

H. Berteaumaux of Spokane and G. A. Henkle of Sprague have bought placer properties on Gold creek, near Orofino, from P. Sawyer.——Another condemnation suit has been started by P. Larson and T. L. Greenough to obtain a right of way for the Morning tunnel No. 6. E. J. Clark, W. P. Wood, D. F. Clark and M. J. McHugh, owners of the Midnight claim, which Larson & Greenough desire to traverse, are the defendants. A right of way for 560 feet through the Midnight claim is sought, the tunnel being 1000 feet long and 12 feet high. This is at a depth of 2100 feet. The appointment of three disinterested persons to assess the damage resulting is asked. This is the second suit of this kind brought in Idaho. Other condemnation proceedings were instituted several months ago by Larson & Greenough to secure a right of way for the same tunnel through the claim owned by Hedlund & Baillie of Mullan. The court decided they were entitled to a right of way, and three persons are now appraising the damage. The tunnel has been driven 8250 feet, and is in the Youlike claim 2100 feet beneath the surface. It is intended to drive it 1310 feet farther, giving a working depth of 2500 feet. The Midnight claim is located between the vein in the Morning and Evening and the mouth of the No. 6 tunnel. The complaint states that the mine cannot be successfully completed or profitably worked by any other tunnel; that the right of way across the Midnight is useful, beneficial and necessary for the draining, working and development of the mine; that no damage can result to the Midnight claim, but on the contrary, the tunnel will be an advantage to the claim.

Summit County.

The new hoist of the American Flag Co. at Park City has been started by Superintendent W. M. Curtiss.

Tooele County.

It is reported that Manager Keifer of the Herschel mine, at Mercur, will put in a mill.

Washington County.

John Green reports that the new shaft of the Blue Jay Extension Co., 18 miles northwest of Stateline and in Washington county, is down 65 feet, with sinking to be continued.

WASHINGTON.

Okanogan County.

A double cable aerial tramway is being put in at the Grand View mine near Loomis.

Snohomish County.

The drift on the Imperial mine at Silverton is in 650 feet and will be continued until a cross ledge which crops on the surface is cut. The greater portion of the ore runs as high as 15% in arsenic, for which the company receive nothing when the ore is shipped to the smelter. ——At the Bonanza Queen mine at Silverton a contract has been let to sink a winze from No. 2 tunnel to make connections with the raise now being driven from No. 3 evel.

Stevens County.

J. L. Magney, manager of the Heckley mines on the east slope of Heckley mountain, 12 miles east of Northport, in the Metalline mining district, reports that the group has 285 feet of tunnel, 180 feet of shaft, 65 feet of open cut and 500 feet of stripping work. The ore is galena and zinc. The company is preparing to move a concentrator from Deer Park, B. C., to the Heckley mine.

Whatcom County.

A big strike of free milling ore is said to have been made on the Columbia group of the North American mine in the Slate Creek district, 60 miles by trail from Bellingham. T. F. James is manager.

WYOMING.

Carbon County.

It is reported that the Penn-Wyoming Copper Co. intends adding furnaces to increase the present smelting capacity of 350 tons daily to 1000 tons daily, and an auxiliary steam plant at the smelter to be used when water power is not available; also a 1000-ton concentrating plant at the mine. They are working the Ferris-Haggarty property at Dillon. The present concentrating plant is producing 300 tons of a 28% product daily. ——At the Doane-Rambler mine at Rambler the lower levels are to be opened up and sinking continued. A large pump has been put in at the 645-foot level. J. L. Powell is superintendent.——The Battle Lake Tunnel Site Co. is working the mine. It is reported that they intend putting in a new water power plant. Preparations have been made to build a dam at the outlet of Battle lake.——Manager Aaron Slothower intends putting in a hoist and continuing the main shaft of the Investors' M. & P. Co. at Rambler.

FOREIGN.

AUSTRALIA.

New South Wales.

The half-yearly statement of the Broken Hill Proprietary shows a profit for the six months ended May 31 of £147,671. Net assets £423,905, and profit and loss account shows a credit balance of £580,470; £16,278 has been expended in construction during the half-year, of which amount £5,499 has been on account of zinc concentration plant and sulphuric acid plant. As the result of modifications in the furnaces at Port Pirie, satisfactory results have been attained in the recovery of metals. Connection has been made between McBryde shaft and Delprat shaft at the 1000-foot level, opening communication from Delprat shaft to not far from the southern boundary—a length of 2150 feet. Delprat shaft has reached a depth of 1120 feet. Cost incurred in prospecting, £22,076. Zinc concentration plant in full operation three months, and this worked satisfactorily, producing 12,851 tons of concentrates for the half-year; contracts are signed for the sale of concentrates at the rate of 40,000 tons per annum, extending to the end of 1907. The erection of the necessary plant for the manufacture of spelter, definitely decided to be situated at Port Pirie, is being pushed ahead as much as possible. The zinc concentration plant has a producing capacity of 1200 to 1400 tons weekly; this quantity is sufficient to meet all requirements for own manufacture, in addition to contracts. Since reporting, in February, 1903, the estimated quantity of ore in sight was 4,250,000 tons; have extracted 1,400,000 tons. In view of latest developments, a fresh survey has been made, and, according to recent estimates, the quantity of ore in sight amounts to 3,200,000 tons, of usual quality. Average prices obtained during the half-year: Lead, 12s 3d per ton, and silver, 49-64d better than during the past half-year. The past half-year completed the twentieth year of the company's existence, and within the time 7,747,306 tons of ore treated, producing 733,025 tons of pig lead, 4576 tons of copper, 7201 tons of antimonial lead, 129,740,728 ounces of fine silver, and 82,933 ounces of gold.

Western Australia.

As a consequence of favorable bore-hole prospecting, the management of the Boulder Main Reef is preparing to sink the main shaft from the 1400-foot level to the 2500-foot level.

CANADA.

The following announcement has been made by the Canadian authorities regarding duty on white lead: "Provided that dry white lead purchased on or before the 6th day of July, 1905, at any place out of Canada for importation into Canada, on evidence to the satisfaction of the Minister of Customs of the purchase and sale having been so made on or before the said day, may be entered for duty at the rate of duty in force immediately before that day, notwithstanding an increase of custom duties under this act, but this proviso shall cease to have force and effect after the 15th day of September of this year." July 6th was the date of delivery of the budget speech.

BRITISH COLUMBIA.

Some time ago the British Columbia parliament enacted a law forbidding the employment of Chinamen in mining underground. The Wellington Colliery Co., desiring to test this law, continued to employ Chinamen in underground work, whereupon an agreed case was submitted to the courts and passed finally to the privy council in London, England, the court of last resort. The judicial committee of the privy council has handed down a decision in favor of the colliery company. The committee sustained the contention of the company that it could send its employes to any portion of its property. Similar acts, relating to both Chinese and Japanese, have been disallowed by the Dominion Government.

Boundary District.

At the Emma mine at Summit the main incline shaft is now down 150 feet, where crosscutting is being done.——Work has been resumed on the Jewel in Long Lake camp with seven men, working under J. H. Smith.

Within the last year the Granby Con. M., S. & P. Co., Ltd., has purchased thirteen additional mineral claims in Phœnix, at a cost of $432,000, the last of which was the completion of the Gold Drop group, purchased for $225,000. The claims purchased were as follows, with their respective amounts: Monte group of four claims, $15,000; Monarch and Tamarack group of four claims, $180,000; Gold Drop group of four claims, $225,000; No. 13 claim, $12,000. It is the intention to open up the Gold Drop at once, by running a raise from the No. 3 tunnel to the surface, and quarrying the ore and dropping it down the raise. Superintendent Hodges states that he expects shortly to begin work on a surface tramway from the Gold Drop to one of the Snowshoe's Central Pacific Railroad spurs, for shipping purposes, the arrangements now being made with the Snowshoe Co. for that purpose. When the tramway is built to this spur ore bins will be built.

Rossland District.

The output for the week ending September 2 was 6540 tons. The Crown Point, after an idleness of several years, has shipped a carload. Shipments for the week were: Le Roi, 3590 tons; Center Star, 2250; Le Roi No. 2, 150; Le Roi No. 2 (milled), 400; Spitzee, 120; Crown Point, 30; Jumbo, 400; total for week, 6540, and for year, 225,653 tons.

Slocan District.

The Bosun mine, between New Denver and Silverton, has been purchased by the Monitor & Ajax Co. of New Denver, which controls also the new zinc concentrator at Rosebery. The Bosun is developed by five adit tunnels on the lead, with a vertical depth of 365 feet and a total length of 1800 feet. The lowest tunnel is 1000 feet long and is connected by raises with No. 2, 130 feet above, which is 800 feet long. Eighty feet above it is No. 3, which is 1000 feet long. No. 4 is 85 feet higher and 500 feet in length. No. 5 is 60 feet above No. 4, 60 feet below the surface at the face and 500 feet in length. The lead is a large fissured zone containing quartz, galena and zincblende. It is announced that the works at Rosebery are completed.——The Monitor Co., of which M. Gintzburger of New Denver is manager, has everything in readiness at the mines and reduction works for operations.

Vancouver Island.

Consul Dudley of Vancouver writes that the Britannia mine, 30 miles from Vancouver, has started shipments of ore and concentrates to the Crofton smelter. The mine lies at an elevation of 3500 feet above the beach at the head of Howe sound. An aerial tramway, nearly 3 miles in length, has been built to bring the ore from the mine to the crusher, which has been built upon the side of the bluff that rises from the shore, at an elevation of 100 feet. From the crusher the ore travels by gravity to the concentrator. The tramway has a capacity of 100 tons per hour. The concentrating plant has sixty tables. The concentrates are carried by gravity to bins at the shore, so arranged that three cars may be loaded at one time by simply opening the chutes and allowing the concentrates to run into the cars. The cars will be brought upon a transfer barge and, when loaded, will be towed across the Gulf of Georgia to Vancouver island, 40 miles, where they will be run on rails to the Crofton smelter. The contents of the cars will be dumped into the bin and the smelting and refining of the concentrates will be carried on day and night. The motive power of the tramway, the crusher and all other machinery, including the compressed air plant used to operate the drills, is electricity, generated on the spot. A small stream, with a fall of several hundred feet, gives power to the generator.

MEXICO.

Durango.

The Parral Miner reports that the Lustre M. Co. at Santa Maria del Oro, Durango, have been running the slag from their smelters into iron moulds of suitable shape for building purposes. These slag building blocks or bricks are cast in iron moulds 8x16x15 inches, with a taper of ⅜ inch all around to facilitate removal from the blocks. These blocks come from the mould smooth and shiny on the edges and rough, with tendency to blister on the top, while the bottom is reasonably smooth, as the mould is set on a heavy iron plate which serves as a bottom. The rough top is found to be an advantage, as it holds the muds or lime in building and helps bind the wall. There is no tendency to split or crack as might be expected in a basic slag. The company has built one house, 22x18x14 feet with 24 inch walls laid in mud, and is completing a second building 38x18x20. The slag blocks are laid up in lime mortar. The slag carries 55% silica and 20% iron.——The Inde Reduction Co. has blown in their La Roca smelter. Their present output is two tons daily.——La Cruz Mineria have completed their 25-ton smelter and will treat their own ores in the future.

D. M. Burns, general manager of the Candelaria mines in the San Dimas district, is having plans prepared for a hydro-electric plant in that district. A mountain waterfall will be utilized, and electric power will be supplied to the Candelaria and other mines and to reduction plants in the San Dimas district.

Jalisco.

The Lupita M. Co. of Colorado Springs, Colo., operating in the Navidad district, has purchased the Socorredora mine on Agujas mountain.——Ore rich in silver and gold has been cut in reopening the Barranca mine in the Ameca district. A force of 125 men is employed. The Barranca mine was purchased by E. J. Callahan for the Bonanza M. Co. A reduction plant at the mine is being built and new machinery will be added.

Commercial Paragraphs.

THE contract which R. W. Christian, gold dredger operator and inventor, has entered into with the Allis-Chalmers Co. gives that company the exclusive rights to his patents, and also his services as engineer in designing and constructing gold dredgers which the company may make embodying his inventions.

THE Rapid-Economy Stamp Mill Co. of San Francisco, Cal., reports a lively demand for their Richards' Rapid-Economy stamp mill. They have a contract to equip the Castle Mont M. Co.'s property in Tuolumne county, Cal., with a number of their stamps, and report the shipment of one of their 3-stamp batteries to F. H. Elder for his mine in Humboldt county, Cal.

N. C. BONNEVIE, president Denver Ore Testing Co., Denver, Colo., has contract for making plans and building a 50-ton stamp mill for the Sound Democrat mine at Animas Forks, near Silverton, Colo., and 50-ton Elspass mill for Max B. Fitch, manager the Southwestern Lead & Coal Co., Socorro, N. M. Both these parties had their ore tested by the Denver Ore Testing Co., and from the tests decided the kind of machinery to use in their new mills.

THE Trenton Iron Co. of Trenton, N. J., have recently built, or are building, Bleichert aerial tramways for the May Day G. M. Co. and the Bonnie Girl M. & M. Co., Hesperus, La Plata county, Colo.; the Howell Hinds Old Hundred mine, Howardsville, Green Mountain M. & M. Co., Silverton, Grand Mogul mine, Gladstone, Ross M. Co., and the Gold Prince mine, Silverton, San Juan county, Colo. It is expected that all the above will be completed within the present season.

STEAM hose in being dragged around rocks, etc., is liable to kink. Kinking breaks the hose from the outside, when the hose, then being unable to stand the necessary pressure, bursts. This kinking is said to be overcome in the flexible steel-armored hose as the nature of the armor maintains a uniform internal diameter. The steel armor of the flexible steel-armored hose entirely covering the inner rubber hose, and being interlocking, prevents an open rupture, with the result that sufficient steam pressure is maintained to continue the use of the hose. A drill or other machine can thus be continued in use with a damaged hose until it is convenient to replace it with another piece. Full description of this new hose may be had from the manufacturers, the Sprague Electric Co., 527 West Thirty-fourth street, New York.

Trade Treatises.

"Smelting Furnaces and Accessory Equipment" are attractively illustrated and described in Catalogue No. 122 of Allis-Chalmers Co., Milwaukee, Wis. The treatment includes blast furnaces for lead and copper ores, hot blast stoves, water jackets, forehearths, slag, matte and bullion pots, charging apparatus, blowers, engines and electrical apparatus.

As an exponent of recent hoisting practice, Catalogue No. 126, of the Allis-Chalmers Co. of Milwaukee, Wis., on "Hoisting Engines and Accessories," is practical and interesting. Besides illustrating many recent examples of fine hoisting installations, it contains much information and data on hoist problems. Its typographical appearance is in accord with the high standard already set.

Bulletins Nos. 1600 and 1601 of the Allis-Chalmers Co. of Milwaukee, Wis., describe tests and records of the 30,000,000-gallon pumping engine installed in the Chestnut Hill high-service station of the Metropolitan Water Works, Boston, Mass., and of the 15,000,000-gallon vertical triple-expansion pumping engines installed in the Baden high-service station of the St. Louis, Mo., Water Works.

"The Automobile Washstand-Turntable," manufactured by the Link-Belt Machinery Co., Chicago, Ill., is the subject of a trade treatise which shows that this appliance facilitates the handling of motor cars in garages and manufactories by enabling the car to turn as on a pivot toward any objective point, thus rendering every part of the garage easily accessible, and reducing the space ordinarily required for maneuvering cars to an extent which greatly increases the capacity of the garage. It permits the car always to face the door, thus avoiding the inconvenience and risk of accident which occur in backing out, especially when the approach is narrow or on a grade.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING AUGUST 22, 1905.

797,711.—JAR FASTENER—Abramson & Bennett, San Francisco.
797,839.—SWITCH—C. J. Carlson, Spokane, Wash.
797,841.—CHAIR—C. Conn, Bremerton, Wash.
797,721.—AGITATOR—M. J. Covell, Los Angeles, Cal.
797,796.—HOSE COUPLING—E. Devlin, San Francisco.
797,767.—WINDOW TIGHTENER—G. H. Dyer, San Francisco.
797,730.—ESCAPEMENT—F. Gundorph, San Francisco.
797,959.—MIXING DEVICE—Hulvorsen & Walls, Vashon, Wash.
797,736.—PENHOLDER—P. L. Keller, Petaluma, Cal.
797,737.—BUTTER CUTTER—N. W. Kline, Long Beach, Cal.
797,901.—ASSAY FURNACE—A. M. MacDuffee, Chloride, Ariz.
797,778.—WHEEL—D. C. McCan, Los Angeles, Cal.
797,779.—WHEEL—D. C. McCan, Los Angeles, Cal.
797,743.—SHOE STRING FASTENER—J. A. McCoy, Sisson, Cal.
797,709.—DIRT SCRAPER—P. J. Petterson, Seattle, Wash.
797,618.—WEDGE—F. P. Sharp, San Francisco.
797,627.—JACK ARM—E. B. Stone, Oakland, Cal.
797,638.—HANDLE—J. L. Thomas, Winlock, Wash.
797,831.—BOTTLE—M. T. Wright, Port Orford, Or.

FOR THE WEEK ENDING AUGUST 29, 1905.

798,386.—FAUCET—S. F. Baker, Santa Barbara, Cal.
798,317.—PLOW—J. Beard, Westport, Cal.
798,393.—SHINGLE MACHINE—W. L. Connett, Sweet Home, Or.
798,323.—CHUTE—C. F. Cormack, San Francisco.
798 576.—LOCK NUT—I. W. Exley, Colville, Wash.
798,278.—QUARTZ CRUSHER—L. C. Graupner, San Francisco
798,334.—FISH TRIMMING MACHINE—C. P. Hale, San Francisco.
798,192.—SIPHON HEAD—D. Landau, San Francisco
798,297.—SMOKE PURIFIER—Lawton & Reynolds, Grants Pass, Or.
798,195.—FIRE PROTECTOR—Locher & Predom, Auburn, Cal.
798,288.—SASH HOLDER—G. Malcolm, Oakland, Cal.
798,299.—DOOR KNOB—B. Phelps, Seattle, Wash.
798,299.—SEWING MACHINE—J. O. Rollins, Tuolumne, Cal.
798,541.—DUPLICATING APPARATUS—G. M. Stroud, Portland, Or.
798,308.—THILL ATTACHMENT—W. J. Thomas, Inglewood, Cal.
798,311.—BUGGY TOP REST—E. Wiet, Sacramento, Cal.
798,150.—CARBURETOR—S. B. Wolgamott, Tancred, Cal.
798,312.—SMELTING FURNACE—H. L. & N. Wrinkle, Keeler, Cal.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

TOOL ATTACHMENTS FOR SEWING MACHINES.—No. 798,299. Aug 29, 1905. John O. Rollins, Tuolumne, Cal. This invention relates to attachments for sewing machines, and particularly to a form of removable tool hanger and means for driving the same from the machine treadle. Its object is to provide a detachable carrier for rotary tools, which may be applied to machines already in use and which will drop below the table to permit of its being run from the main drive wheel without interfering with the table or requiring changes therein, and to provide a novel and efficacious means for operating the tools from the treadle of the machine and without necessarily running the sewing arm. It consists in the combination with the frame casting and operating treadle of a sewing machine, of a detachable arm arranged to be secured thereto, means including a bolt passing through the frame casting and plates on the bolt upon each side of the frame for detachably securing said arm to the side of the frame casting, a direction pulley and a flexible connection passing over said pulley between said arm.

FISH TRIMMING AND SPLITTING MACHINES.—No. 798,334. Aug. 29, 1905. Cress P. Hale, San Francisco, Cal. The object of this invention is to provide a practical labor-saving device which will automatically remove the tails, fins and head of large-sized fish, such as salmon and the like, and which will split the fish along the back to allow the removal of the backbone. The invention comprises in fish-dressing apparatus, the combination with fish-conveying means, of a table on which the fish is delivered therefrom, a rough-shaped carrier extending in the direction of movement of said conveying means and operatable at right angles thereto and across said table, means for delivering the fish from the table into said trough, and a cutter to one side of the path of the trough to sever an extremity of the fish.

Dividends.

Bunker Hill & Sullivan M. & C. Co., Idaho, dividend No. 96, $150,000, payable Sept. 4; total paid since Jan. 1, 1905, $2,625,000; total to date, $4,896,000.

MINING AND SCIENTIFIC PRESS.

Whole No. 2354.— VOLUME XCI. Number 12. SAN FRANCISCO, CAL., SATURDAY, SEPTEMBER 16, 1905. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

The Prospector, Etc.

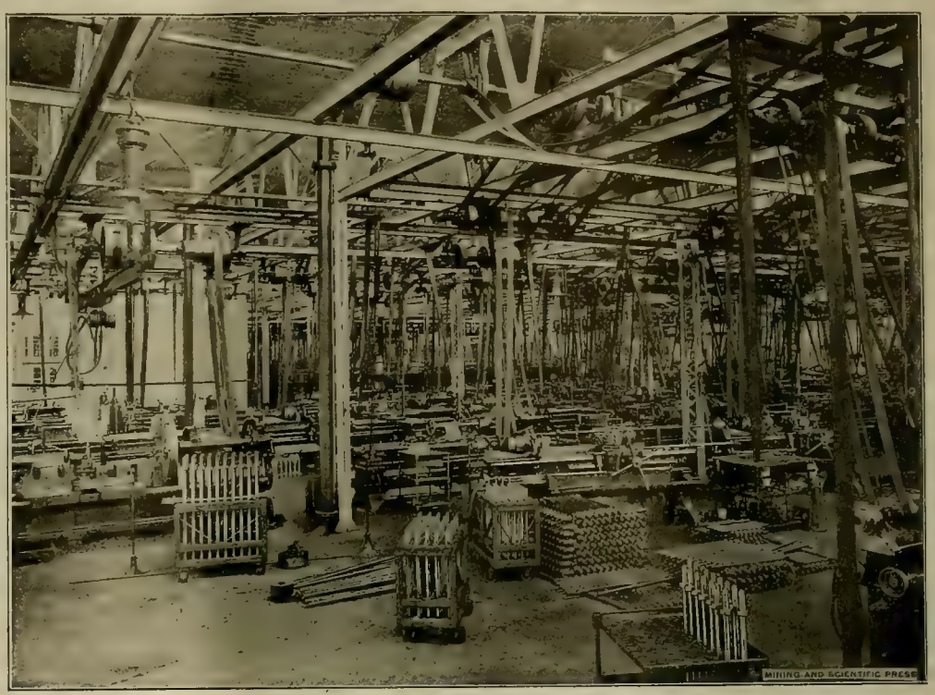
In a recent lecture on "The Laboratory and the Gold Mine," by Prof. S. L. Bigelow of the University of Michigan, emphasizing the need of mining and scientific research, and the absolute requirement of technical skill in mining, he said that time was when the treasure seeker in the mountains needed only a pan in which to wash the sand to determine if the prospect was a good one, but that nowadays the first requisite was the installation of costly machinery and that the day of the prospector is over.

It is singular how this latter idea clings to the minds of so many people; possibly it is because of their environment. The professor was right in recounting the achievements of mining and metallurgical science and in stating that knowledge of the sciences connected therewith is absolutely necessary for success; but he was wrong in assuming that "the day of the prospector is past." It is not, and it would be a sorry day for the mining industry if it were. The prospector with his pan, his scanty outfit and his patient, humble work is still the avant courier of the mining industry of America. He is still the sturdy pioneer that blazes the way and makes the initial discovery that renders possible the mining camp and all the busy life that clusters round a great mining property. As the acorn holds within its tiny cup the potentiality of the mighty oak, so in the kit of the prospector is the germ of the great subsequent investment—the development of the mine, the purchase of machinery and the outlay of vast sums of money.

This is not always easy to be realized by any one not acquainted with the eternal conditions that necessarily make it so. It is one of the things, to explain which is unnecessary to one that can understand it and useless to one that can not.

No man can thoroughly understand it if he forever lives his life where there is no unoccupied Government land, and hence no possible area for the prospector to wander in. For wanderer he is, and he must have an area of public domain to roam over. Forever filled with an unrest and a spirit of divine discontent, forever hopeful of finding something better than before, he and he alone is the real mine discoverer. He is by no means extinct; in his methods he differs little from his predecessors; in his results he is more fortunate in these advanced days of scientific mining, of which the professor quoted represents in many ways an honored adjunct. He has his sphere; the prospector his, and, with all due deference to the professor, the prospector is at least as important. Were it not for the prospectors, some of the professors would be without business. The prospector is as the voice of one crying in the wilderness, "Prepare ye the way of the Lord!" or words to that effect.

Nor is the professor particularly happy in his suggestion that the installation of costly machinery should be a primary proposition in the development of a mining property. That should be about the very last thing done on the property, and in a well managed mining proposition occupies the final place in the whole scheme. From the prospector's find to the installation of costly machinery is ordinarily a long and evolutionary process, and the ordinary modes of such evolution can not be hastened, reversed or disturbed without considerable disregard of the regular rules of business.



Drill Department, Ingersoll-Sergeant Co.'s New Plant.

Foundry, Ingersoll-Sergeant Co.'s New Plant.

Court Between Foundry and Pattern Storage Buildings.

THE NEW INGERSOLL-SERGEANT PLANT AT PHILLIPSBURG, N. J. (See Page 193.)

WITH impulse wheels to which water passes in planes at right angles to their shafts, it is desirable, in order to avoid changes in the directions of water pipes, that direct connected wheels and generators occupy the same room. This is the arrangement at the Colgate, Cal., Electra and Santa Ana, Cal., electric power houses. The area of a wheel room may frequently be reduced at stations operating direct current, horizontal pressure turbines, under low heads, by placing the wheels at the bottom of the canal, which has one side of the station or generator room for a retaining wall. Vertical wheels direct connected to generators must be directly under the main room of their station, and may be in a canal over which the station is built, in a wheel room that forms its lowest part, or in a wheel pit, and supplied with water through penstocks, as at the Niagara Falls electric plants.

IN connection with the expansion of American business in Russia is to be noted one of the first fruits of President Roosevelt's mediation between Russia and Japan. In cordial appreciation thereof, the Russian Czar has ordered a discontinuance of discriminating duties on American manufactures in Russia, which takes off from 20% to 30% duty on all kinds of American machinery imported into Russia, and which will thus tend to largely increase the American mining machinery trade with Russia.

THE operators of the large coal mines on Vancouver Island, B. C., appear to have gained a victory in the test case which was tried to determine whether the law of the Dominion Parliament, making it unlawful for mine operators to employ Oriental labor underground, was good law. The case has been carried up from one court to another, eventually reaching the Privy Council in London, the British court of last resort. This high tribunal decided in favor of the mine operators. An ultimate decision was reached much more quickly than is usually possible in the United States.

TO except mines or mineral lands from the operation of a townsite patent, it is not sufficient that the lands do in fact contain valuable minerals when the townsite patent takes effect, but they must at that time be known to contain minerals of such extent and value as to justify expenditures for the purpose of extracting them; and if the lands are not known at that time to be so valuable for mining purposes, the fact that they have once been valuable, or are afterwards discovered to be still valuable for such purposes, does not defeat or impair the title of persons claiming under the townsite patent.

A National Need.

The Canadian Government is about to accede to the requests of Canadian mining men and establish a National Department of Mines at Ottawa, under the direction of a Minister of Mines. The idea is a commendable one. As a cold business proposition Canada will make money by it. Such governmental department will pay for itself ten times over in the first year of its existence. Such a government department will foster and aid the mining industry of the Dominion in many ways.

For many years the necessity for a national Cabinet Department of Mines and Mining has been urged as a requisite part of the executive branch of the United States Government. The objections against the measure have been met, and the arguments for so salutary a step are now unanswered because unanswerable. The only objection noted of late is that the supervision of the mining industry can be left to the several States and that the general government need not be burdened with such proposed federal supervision. Such argument is born of ignorance and has no excuse for existence. If the mining industry were solely a State matter; if here and there throughout the nation there were only a sparse and sporadic evidence of its existence, then, as in similar cases, it might well be left to State supervision. But it has become the great basic industry of the nation. Many things the several State governments can have justly delegated to them for sole control: in the case of the mining industry it is due to its dignity and importance that it be accorded the fullest measure of federal recognition. In our system of government the federal power is dominant, and when it stamps the seal of paramount authority upon an industry, it lifts it to a height of industrial importance denied to anything controlled by State measures. To such dignity would the mining industry be raised by the creation of a Cabinet of Mines and Mining.

But it is not a matter of "dignity" so much as a plain present business requirement. The importance of an industry that last year produced twelve hundred millions of dollars is manifest, and justifies such Cabinet creation. It has always been the wise policy of the Government to create Cabinet departments in accordance with the growth and requirement of the nation. In the early years of the Republic the Cabinet of the President of the United States had but four officers. As we advanced it became necessary to have a Secretary of the Navy; later, the nation needed a Postmaster-General. Doubtless in those days there were men who shook their heads and thought it was unnecessary and extravagant to have so many Cabinet officers. But in 1848 it was found necessary to create a "Department of the Interior," and any one who has had anything to do with land or mines in the last half-century knows how overcrowded and overdone is the little section of that Cabinet department that is devoted to those matters. Since the first recognition of mining in the United States a little desk in an obscure corner of the Interior Department is all that is accorded the great industry that made the nation what it is and maintains its strength and prestige through the years.

In 1889 it was found needful to create a Cabinet Department of Agriculture. In 1903 was created a Department of Commerce. Every dictate of justice, economy and good business requires that there be created a Department of Mines and Mining, an officer as member of the Federal Cabinet. As shown, the President's advisers and assistants have grown in number with the growth of the country. The time has come when the industry that has made all others possible be given its due representation in the executive branch of our Federal government. It would be a good investment in every way.

And in this there is no plea for aid nor call for assistance; no hint at fostering care or protection; no request for favor or help of any kind. The American miner is perfectly able to take care of himself and asks no governmental help. He does think, however, that the Government exhibits a lack of understanding of its own true interests in its neglect to help itself. What mining is in 1905 is only an indication of what it can be made to be. We have illimitable mineral resources; abundance of capital; the highest quality of technical skill. There are many present limitations on all these because of the lack of proper governmental representation. Men who have a clear conception of national requirements see this; a broad-guage policy requires that the deficiency be supplied. In former arguments for the creation of a Cabinet Department for Mines and Mining, this journal has gone into details illustrative of the pressing need from a national standpoint of this measure. When the MINING AND SCIENTIFIC PRESS began the effort there was considerable apathy. There is a little left, and it is this indifference alone that has prevented the mining men of the United States from having a Cabinet Department years ago. Concert of action would secure a Cabinet Department of Mines and Mining inside of two years. Whenever the mining men want it they can have it by giving the national legislators to understand that votes count, and that mining men the country over know their friends.

NO kind of engineering has developed so fast as electrical engineering. The electrical engineer has an unusual advantage over other engineers in the fact or existing condition that in his line everything lends itself to exact calculation, and a completed machine or any of its parts may be submitted to the most searching electrical and magnetic tests, because such tests, unlike those applied by other engineers, do not destroy the body tested. In mining, tunneling, earthwork, building, making railways or canals, the engineer is supremely dependent on the natural conditions provided for him, and these conditions are seldom twice the same. The rock is different, the ore is dissimilar, the ground is not alike. There are no simple laws known to the engineer about the way in which currents will act upon sand and gravel; and engineers who have had to do with such problems are continually appealing to nature, forever making tests and observations, and bringing to bear upon their work all the knowledge and habits of thought that their past experience has given them. But the advantage cited in the case of an electrical engineer is sometimes set off by the concomitant fact that because of this as a finished product the electrical engineer must not overlook the need of training in the exercise of his judgment in actual, practical work.

THE growing importance of mining is being variously illustrated. Uncertainties in industrial stocks, the glut of cheap money, the strenuous competition in mercantile and manufacturing as contrasted with the profits of intelligent mining work, induce investments tremendous in the aggregate. Noticeable, too, is the increase in the number of students who in the different universities take up the "mining course." With requisite training and experience, the graduate of a mining college can be a good miner or mining engineer, the chief advantage of his college education being the "right start" he has secured; but in this matter nothing can take the place of experience, and this can only be had by actual work and responsibility. This influx of young men who in entering a mining college for a four years' course dedicate their lives to the profession of mining is also illustrative of the recognized importance of the mining industry, by reason of the fact that in mining, as in other important industries, it is the young man who has charge of affairs, and to the properly qualified man the mining industry affords fine opportunity for a prosperous career.

THE Supreme Court of California decided that any one who connects himself with the title of a mining corporation may take advantage of the law of that State prohibiting the directors of mining corporations from selling or encumbering its mining grounds unless ratified by the stockholders. In the case of Williams vs. Gaylord, 186 United States Reports, 157, the Supreme Court of the United States has decided that such decision is binding on the Federal courts; that is, a State may require the consent of the stockholders of a foreign mining corporation as a necessary prerequisite to the sale or encumbrance of the mining ground owned by it within the State, as such a requirement is not a regulation of the internal affairs of the corporation, but has reference to the conduct by it of its business.

The Deadly "Knocker."

A letter from a little town in northern Idaho says, as usual, that there is nothing needed there but capital—that the indications made manifest by the development work already done show conclusively that all that is required is capital to make three or four big mines. Very likely; indeed, almost positively so. The same assertion is made to this journal over and over again in the course of a year, and usually what the correspondent says is the truth. But it is not the whole truth. Such correspondent from northern Idaho, or southern Oregon, or eastern California or western Colorado, the same as other correspondents from many other promising localities throughout this west half of America, omits one important requisite not usually possessed by the denizens of a promising mineral region, namely: co-operation, which involves the absence of local antagonism.

It is, too often, the experience of would-be investors in a deserving mining prospect that some one on the ground—some local resident—will often do his best or worst to "knock" the sale of his neighbor's property, sometimes from pure cussedness, other times because he himself has a property that he wants to sell, and sillily knows no better way to recommend it than by decrying his neighbor's ownings. One or two such male specimens can kill a camp or hold back a really deserving mining locality.

It is within the writer's personal experience to be approached on his visiting a place that "needs nothing but capital," and confidentially told by a leading local light that the property under consideration was "n. g.," and that "no one but a damned fool would buy or bond it," meanwhile affording the information that he had a really fine proposition, just what was wanted, and might be induced to consider suitable offer therefor. This is not an uncommon experience. Of course, the almost inevitable result is that the visitor leaves on the next stage—and sometimes has reminiscent remarks not wholly favorable to further inquiries concerning that particular locality.

That this is the acme of folly goes without saying, but it is just what is being done over and over again in a hundred deserving localities.

Such people might with great benefit take a leaf from the ledger of real estate men's policy. If a "stranger" visits Brownstown or Silverville, and talks of buying a lot, the local real estate dealer to whom the "stranger" talks doesn't tell him that he has the only lot in town worth buying and the other fellows are only false alarms. He sensibly credits the visitor with the possession of ordinary intelligence (which is usually safe), and contents himself with effort to sell the lot in question, telling the truth (which is good enough, and most folks believe it). Should the visitor finally buy a lot from another real estate agent in the same town, the first one talked to says, usually: "That is a good lot, too; indeed, next to the one I showed you, I believe I would recommend it for your purpose."

Were he to start in telling the would-be buyer that that lot was badly located; that the property just there would depreciate, and that the whole was worthless, he would do no worse for the place of his habitation than the man who "knocks" the sale of a mining prospect in his locality.

"Then," it may be asked, "would you advise that an innocent purchaser be kept in ignorance of the situation? Is it not common honesty to let an investor know the defects and shortcomings of a property? Is it not the duty of a resident, acquainted with the facts, to so inform one uninformed?"

If there be swindling or false misrepresentation going on it is only right that the poor innocent promoter or mining engineer (who of course knows nothing), be told of his folly, but, generally, it is not with any such high ideal of his duty to his fellowman that the "knocker" does his deadly work. He "knocks" because his own narrow envy and little lust for lucre blinds him to the injury he is doing his locality. He is not fooling the promoter nor mining engineer into believing what he says about his own property, but he is helping to throw suspicion upon any honest statement of others, for in nothing is confidence more easily destroyed than in anything relating to the purchase of a prospect.

This is not a lecture nor a sermon, nor even to be considered as advice, but is, perhaps, a harsh way of saying what has been said herein before in more courteous terms, viz., that nothing is ever made and much is often lost by false and foolish statements made by local residents about their neighbors' property.

Many a good sale has been spoiled; many a deserving locality is dead or dying, because of the lying tongue of some resident idiot who is denied the sense that God gives to geese. Such a locality is unfortunate in possessing such an undesirable specimen of inhabitant, and if ever a boycott was justifiable it is in his case.

THE appreciation in the price of silver is of interest from either a mining or monetary standpoint, solely that it produces more profit at its present price to the miner. Indeed, in some cases where silver is a product, there is more money for the miner with silver at 62 cents than when it was $1.34 an ounce, thanks to improved metallurgical methods, gerater facility for transportation, and decreased cost of supplies. So far as the monetary question is to be considered, the parallel of anomaly is considered coincident. With silver at 50 cents an ounce, or 25 cents, or 62, as at to-day's quotations, the business of the world would adjust itself to the fluctuation. The currency or its value is unaffected by the current price of silver, for, in the United States, the silver dollar is in the last analysis merely a government note stamped on silver. The material counts for nothing in giving it circulation value, any more than does the paper on which national bank notes are printed. Should silver go to $1 per ounce, or drop to 25 cents, our currency would remain unaffected, provided the total amount of unexportable money in circulation here was kept within the amount that could find employment at par.

THE Transvaal, South Africa, Government has appointed a commission of twenty-four members to inquire into and report on the present practice in the matter of conveying persons in mine shafts, more especially with reference to winding ropes, their structure, material, preservation, examination, best method of attaching rope to load, and the reliability and adaptability of safety catches and appliances in shafts. There are five printed pages in the schedule received at this office, covering the entire subject in an exhaustive manner. The commission asks for technical testimony from any and all who are acquainted with the subject sufficiently to make their evidence of any material value. They would likewise be pleased to have manufacturers of devices connected with the subject furnish drawings, models and plans of such devices, with full descriptions of their workings. It will be necessary for each manufacturer submitting drawings or models to grant permission to construct the appliance in question for test purposes. The schedule may be seen at this office by any one interested. Anything sent in connection with the subject should be addressed P. O. Box 1132, Johannesburg, South Africa, and reach the secretary there not later than January 31, 1906.

IT sometimes occurs in statistics of ore shipments from mining districts that the figures would indicate decreasing values. But that is simply illustrative of how delusive statistics can be. It is the ordinary history of every mining district that after the first two years the ore shipments showed a lesser average value, manifestly because decrease in freight and increase in smelting or milling facilities made it possible to ship ore that in first conditions wouldn't pay for shipment or treatment. True statistics rightly elaborated would almost invariably bear out this latter view. A district might have shipped $100 ore two years ago, and now be shipping ore that goes only $20; but of the $100 ore only 20,000 tons were shipped, while of the $20 ore 200,000 tons is going out, the fact being that the camp is now shipping $4,000,000 value of ore, where two years ago it was shipping but $2,000,000.

THE owner of a ledge, lode or vein may follow it upon its dips or pitch beyond his side lines and into the adjoining claim, provided that the apex of the lode is upon the claim of the one who seeks to follow it; provided, further, that the lode is a continuous one, and that the end lines of the claim are parallel. With any one of these three conditions non-existent, the Federal mining law will not permit the owner of the lode to follow it beyond his own lines.

Quarreling With the Creator.

That "divine discontent" which impels desire to better one's financial condition is always commendable, but we have no sympathy with those who content themselves with futile complaint of the "unequal distribution of wealth," and who talk as though some one was doing them out of their share. The man who attacks the possessor of money without having the ability to acquire some himself is merely attempting to institute a quarrel with the Almighty because in the distribution of talents the gift of acquiring wealth was denied him. For a money-getter is merely a man who has ability in that direction and who exercises it. He can no more help making money than the man devoid of such a gift can help being without much of it. It is as useless to "kick" at the unequal distribution of the money-making talent as at similar unequal distribution of the inventive talent, or the musical talent, or the poetic talent, or the scientific talent, or the talent that makes an efficient mine manager. The world of invention is open to every one, and the fame and profits resultant from successful invention are the prizes of him who can win them; yet it would be ridiculous for any one to inveigh against Edison or any other great inventor because his mental endowment was not equal to producing such great inventive results.

It would be equally ridiculous for one to utter outcry because of his inability to write like Kipling or Conan Doyle or Winston Churchill. A "kick" against Tennyson or Shakespeare or Burns because of inability to write such poetry as they wrote would be as logical as this eternal bleat about the "monopoly of money power" by those who have no money-making ability.

As well declare against a Bessemer or a Roebling; a Hewitt or a Melville; a Oyama or a Roosevelt, or any men in any age made famous by deserved success, by the exercise of natural gifts. Of as much real purport to decry the achievements of the electrical or mining engineer because the success that has followed their intelligent efforts is not shared by the envious witness of the well-earned fame that fills the earth. Of course if it be bad to have men who can invent or write poetry, or make money, or create success of any kind; if the ability to do these things be a "monopoly," then let us all decry and defy this monopoly of talent and take steps to have such monopoly in any line destroyed. Why should Patti be paid $2000 to sing a song when the writer couldn't get a thousand cents for as many ditties? Of what justice is the fact composed that permits Kipling to get $500 for a short story when many of us couldn't get 5 cents for the longest kind of a yarn? How shameful a fact and full of menace to mankind is the sad spectacle of an Edison getting $50,000 for an electrical device that adds $50,000,000 to the wealth of the world, when we ourselves are unable to think up an improvement in a hen coop!

What an outrage on the natural rights of man for some miscreant to invent a cyanide process, or a water-jacket furnace, or a concentrator, even though such devices add thousands of millions of dollars to the world's wealth, where the railer at such wealth hasn't sabe enough to see pay ore in an outcropping! Let us take away the talent for doing anything well from the possessors thereof and drop everything to the dead level of mediocrity. It is an outrage to which no free man should submit that any one should be able to get wealth or renown because of individual talent or effort when such success institutes so damaging a comparison between relative mentalities!

Mind will always rule matter; brains will always win; intelligent and honest effort in any line, whether wealth, poetry, science, literature, music, mining or engineering, will invite success, and it is inane for any one to lose time in envious carping at those who substitute perspiration for inspiration, and who work at their chosen avocation first for the joy that a true worker finds in congenial work, and second for the material success that it brings.

CONCENTRATES.

ROSIN dissolved in alcohol will give a flux that will not corrode in soldering wire or electrical connections.

IN generating steam at 125 pounds pressure from feed water at 62°, about 25% of the total heat required is needed before steam temperature is reached.

COPPER can be welded by being first treated with a solution of nitrate of potassium and a cyanide, after which it can be welded either to itself or to iron or steel.

A MAN can stand a temperature of 122° F. and work therein when the air is comparatively dry; but in air saturated with moisture 104° F. would prove fatal to human life.

THE generally accepted value of a mining property is based to a great extent upon assumed knowledge of what it will pay as distinctive from what it may pay, with a fair allowance for future possibilities.

PALLADIUM is not in much demand. It is used to a limited extent by makers of chronometers, surgical and optical implements. It is found in connection with platinum and also with nickel in Canada.

THE best wooden tanks for metallurgical purposes are made of redwood. Pine, spruce, fir and other resinous woods are less suitable. Steel and galvanized iron are also successfully used in cyanide work.

AS BETWEEN adding quicksilver to the mortar of the stamp mill or simply on the plates, it depends largely on the ore. The personal experience of "Concentrates" favors the addition of mercury to the mortar.

THE Idaho statement does not show sufficient cause for contest. To constitute a valid contract (one that can be enforced by law) five things are necessary—competent parties, sufficient consideration, mutual assent, lawful subject matter and time of performance.

TO CASE HARDEN set screws, make a mixture of equal parts pulverized prussiate of potash, niter and salammoniac. Heat the screws a dull red, roll in this powder, then plunge them in bath of four ounces salammoniac and two ounces prussiate of potash dissolved in one gallon soft water.

REGARDING belt creep, it is to be said that for a common leather belt, running under ordinary conditions, the creep should not exceed 1%. This is usually styled "legitimate slip," but is an actual loss of power and can not well be prevented by patent pulley coverings nor belt tighteners.

A "PURE ZINC SULPHIDE" would contain 66⅔% zinc and 33⅓% sulphide. Leadville, Colo., zinc ore will average about 42% zinc. Carbonate of zinc will carry about 50% zinc. Zinc ore is reduced to a metallic state by distillation. A zinc ore carrying less than 20% is not commercially profitable.

COAL of good quality is widely distributed through Alaska and, with increased transportation facilities, will be utilized. The lignitic coal on Cook's inlet is now being mined in a small way for local use. The short seasons and absence of harbors have deterred the coal development of the peninsula.

THE Philadelphia & Reading Railway, in Pennsylvania, is believed to be the biggest coal carrying corporation in the United States. It annually carries about 9,000,000 tons of coal. There is probably no other railroad system in the country that does so much business and makes so little profit.

BAUXITE, the raw material from which aluminum is most economically manufactured, is produced in the United States to the extent of about 20,000 tons annually. About the same amount is imported. Cryolite is not mined in the United States; it is almost solely produced at Ivigtut, Greenland.

INVENTION does not always constitute discovery. It is not difficult to invent or devise a machine that will serve a useful purpose, though that would not be a discovery, which is quite another matter. When one can make a discovery in mechanics or science, he has achieved something rarely vouchsafed to the most gifted.

IT is possible to live and breathe and work for some hours under a pressure of two and one-half atmospheres (about 37½ pounds per square inch), but a greater pressure would tend to produce paralysis. The pressure under which men worked in the building of the St. Louis, Mo., bridge was one of over four atmospheres (63.7 pounds per square inch).

MINERALS, crude or "not advanced in value or condition by refining or grinding, or by other process of manufacture," are admitted free of duty into the United States. Zinc ore as mined comes under that head. The duty on zinc in blocks or pigs is 1 cent per pound; in sheets, 1¼ cent; manufactured, 35% ad valorem. Zinc sulphate comes under the latter heading.

SILVER cyanide may be prepared by precipitating the nitrate with alkaline cyanide. It is a white powder; specific gravity 3.94, which on being heated melts and loses half its cyanogen. It is converted into chloride by chlorine water, or hydrochloric acid. It may be prepared by dissolving silver chloride, cyanide, carbonate or oxide in a solution of potassium cyanide.

A RECIPROCATING ENGINE which is turning over slowly, with the throttle valve just off its seat, or with by-pass open, and having all its oil cups open and regulated, can be brought up to speed seventy-five turns in two and one-half minutes. If the engine is cold all over and has all its oil cups shut tight, and all its auxiliaries quiet, fifteen minutes would be a quick start.

OSMIUM is of the platinum group and is reduced by alloying the residue which remains when platinum is dissolved in aqua regia, with zinc, lead or tin. The osmium-iridium thus passes into a finely divided state, and, when heated in a current of oxygen, splits up into osmium tetroxide and iridium. Osmium may then be obtained by treating the osmium tetroxide with any reducing agent.

THERE are numerous disinfectants and purifiers of water. The one in every way the best is chloride of silver. The addition of two milligrams of this chloride to a liter of most impure water will completely sterilize it, the purified water permanently remaining so disinfected. Tincture of iodine—three drops to a quart—will sterilize water, but the water will taste of iodine, and the sterilization will not last an hour.

TIN is mined and smelted crudely and spasmodically at Santa Barbara, Guanajuato, Mexico. The country rock is rhyolite; the ore formation is cracks in the rhyolite filled with clay. It averages about 0.5% metallic tin. It is a tin oxide. It is smelted in small native charcoal furnaces. About 40% of the ore contents is the result. Roasting or reconcentration are ineffectual, and the impurities are insoluble in acids.

ALL silver ores, however complex, can be treated by amalgamation after a preliminary roasting with salt; but this, while adding greatly to the expense, gives rise to an additional loss by volatilization, and in most cases unless an ore can be amalgamated direct—that is, unless it is fairly free from base sulphide minerals—and the gangue is mainly quartzose or earthy, it is preferable to adopt either a smelting or a lixiviation process.

A PLACER LOCATION, even though taken by legal subdivisions, is required by law to be staked or marked on the ground. In the case of Mitchell vs. Olive (84 Cal., 409, 24 Pac. Repts., 164) it was held that: "The location of placer claims, using the names of persons as co-locators who are not intended to have any real interest, but who are to convey the rights after location (commonly called dummy locators), is a fraud upon the Government."

HIGH extraction of values from ores is always desirable, but the expense of obtaining high percentages of extraction may prove greater than the net result justifies. There is usually a point where the greatest profit results, and this, from a commercial standpoint, is the point the metallurgist should strive to reach. It is always permissible and proper to increase the percentage of extraction, but if it be done at a loss of profit there seems nothing to justify the effort.

SO FAR AS "inducements" are concerned, the present Arizona charter law regarding foreign and local corporations therein is certainly very "inducing." There is no annual tax, or tax on the amount of capital stock, no annual statement is required, no examination of the affairs of the corporation is called for or permitted, and the Legislature which has made the Territory itself the sole medium through which this business is transacted has not reserved the right to repeal a charter.

THE quantity of water discharged through the nozzle of pipe under known head may be approximately determined as follows: Extract the square root of the head in feet and multiply this by 8.03. The product will equal the spouting velocity in feet per second. Multiply the area in feet of the nozzle at the mouth by this velocity and the result equals the cubic feet of water discharged per second. Thus a 6-inch pipe under a 400-foot head will discharge $\sqrt{400} = 10 \times 8.03 = 160.6 \times 0.19635 = 31.533$ cubic feet per second.

WHEN attempting to operate the decantation process in cyaniding the pulp should not be too thick. There should be abundance of solution with the slimes if success is to be obtained at all. Some kinds of material can be worked somewhat thicker than others. For instance, extremely fine sands, so fine as to be considered slimes, may be settled with a less percentage of moisture than talcose slimes. Practical sense must be used in these operations, for there is no rule, but the result of experience, which may be safely depended upon.

IN a noted construction of concrete the specifications for mixing and placing required in part the following: "The sand and cement shall be thoroughly mixed dry, then sufficient water added to make a plastic or wet mortar, and the whole thoroughly wet again. The broken stone having been previously wet down, shall then be added, and the whole mass thoroughly mixed until every particle of stone is covered with mortar. The concrete thus mixed should be immediately placed in position and rammed until excess mortar shows over the entire surface.

AS HAS BEEN many times previously stated, questions to which these brief paragraphs are answers cannot be published for two reasons—want of space and natural disinclination on the part of the inquirer to have such publicity given him. The questions themselves would transcend our limits, and even the answers have to be boiled down to the briefest space consistent with accuracy and clearness. Unless the journal is set in finer type it is not likely that more than the condensed answer can be given. An attempt some years ago to use smaller type in these pages brought so much adverse comment that the present style of large type was continued in use.

IN an estimation of copper by potassium permanganate the copper in solution rendered slightly acid with hydrochloric acid is reduced by sodium sulphite or sulphurous acid previously nearly neutralized with sodium carbonate and precipitated as cuprous thiocyanate, boiled and filtered and washed thoroughly with hot water onto a filter, the funnel inserted in the neck of the precipitation flask and a boiling 10% solution of caustic soda passed through twice, and the alkaline thiocyanate resulting rendered acid with sulphuric acid and titrated with decinormal permanganate.

IT is hard to say just what should be the measure of responsibility of a contractor in carrying out a piece of work that was planned by some one else, circumstances entirely determining the rights in the case. The contractor generally prepares his own plans and submits his working drawings to the engineer in charge for approval or change. Contract drawings cannot always be considered available as working drawings. It is always best to have a thorough preliminary understanding between contractor and engineer before the actual work begins. A little extra time and expense at the start will save considerable of both later on.

IT has been more than once suggested that in the smelting and refining of zinc gold slimes a furnace built somewhat along the lines of the Bessemer converter would do the work with less cost and inconvenience than that occasionally made necessary. It has been suggested that instead of heating a large number of crucibles, the precipitates, mixed with requisite fluxes, be melted on an open hearth, this hearth to be supported on a hinge and maintained in a horizontal position by a hydraulic jack. After completion of the melting it would be but necessary to open a tap and allow the slag to flow slowly into a cone, the melted gold to be received in a mould.

FIR, PINE and other resinous woods are not as suitable for the construction of tanks as redwood, for several reasons. Pine, etc., always contain pitch, and if from any cause the pitch is driven from the wood leaks are almost certain to result, and pine does not stand changes of temperature as well as redwood. If the settling tank leaks, it is probably due partly to faulty construction of the tanks. Oakum is a better material to use in calking tanks than candle wick, as it swells and has a decided tendency to fill the space completely, thus stopping leaks. In a hot and dry country like southern Nevada pine tanks cannot be as satisfactory as either redwood or metal.

FLUMES in very cold countries may be kept from freezing by placing them on the ground, covering the tops and allowing them sufficient grade to give the water a rapid but quiet current. All sharp curves must be avoided, and also any inequalities of surface which would have a tendency to create any overflow, splashing, or any other disturbance of the water, for at such points ice will promptly form and soon result in serious trouble. If it becomes necessary to carry the flume across a gulch on a trestle, it must be made as nearly water tight as possible, for if it drips the cold will soon form large icicles, which may so overload the strength of the structure as to cause it to fall.

THERE are mining engineers who are paid $25,000 annual salary, and that is not considered the limit, as some distinguished members of the profession are credited with receiving more than that. Such a salary is by no means an unusual one among railway men, some of whom receive $50,000 a year. As to whether any man can make himself worth that amount of money to any concern per year, it may be said that while no one might "earn" that amount in the ordinary acceptation of the term, yet where a man by knowledge, experience and judgment can save or make, say a million a year, to the company he represents, 5% of that would represent his salary, and there are many broad gauge engineers, miners and railway men capable of such showing.

THE height of a mill from the concentrator floor to the point where the ore enters the building depends generally upon the series of processes through which the ore must pass, and varies from 60 feet to 100 feet in a gold mill. The latter includes delivery bins above the breakers, tandem breakers, storage bins, with abundant space

at every step of the process. It is a common mistake to allow too little vertical height, for instance, between the battery or plate floor and the concentrator floor. Twenty feet is not too much, as, if hydraulic classifiers are to be used, all of this room will be utilized. It also admits of the use of mercury traps and allows plenty of grade to launders. If cyanide works are to be included below the concentrators, the vertical height required may be as much as 160 feet.

BY CAREFUL experiment it has been determined that in plain mortars permeability depends upon the voids in the sands. A mortar not poorer than 1 cement to 2 sand will not leak, no matter what kind of sand is used. Mortars consisting of 1 cement to 4 sand will be impermeable if made of a normal mixture of sand—an unsized sand, having the normal variation in size of grains—and any mortar will become impermeable if the water in contact with it carries solid matter in suspension. A coating of neat or clear cement ¼ inch thick will render any mortar impermeable. Where soap and alum are used in cement mortars to render them impermeable, they do not at once become so. Generally speaking, it is more satisfactory to make a higher grade mortar—use more cement, which insures a better result at little, if any, increased cost.

NATURAL AND HYDRAULIC CEMENTS are produced by a simple process of eliminating the carbonic acid from clay-bearing limestone at a temperature of 1000° F. Portland cement is the result of exact chemical and mechanical mixture of lime, silica, alumina, magnesia and sulphuric acid in due proportions, calcined at a temperature of 2000° F. When mixed with water, Portland cement becomes a plastic mortar. Concrete is a mixture of cement with sand, gravel or broken stone. "Armored" or "reinforced" concrete is when steel is added to strengthen the mass. The steel is in bars, beams or wire netting, the cement being usually poured around the metal and allowed to set in a mould. "Slag" cement is the product obtained by pulverizing, without calcination, a mixture of granulated basic blast furnace slag and slacked lime.

IN electrical precipitation of gold from cyanide solution, the solution is permitted to flow through a mass of hard fragmental carbon, packed round the porous cup of an electrolytic cell and connected as the cathode of a circuit of and EMF of 15 volts. The anode consists of a carbon plate immersed in a solution of caustic soda contained by the porous cell. Upon passage of the current the gold is deposited in pulverulent form through the mass of the cathode. The two compartments are then emptied of their solutions, a carbon plate silvered and rubbed with plumbago substituted for the carbon aniode, and the current connections are renewed. A strong solution of potassium cyanide is then made to flow successively through the anode and cathode compartments, in the order named, and the recovery of the gold in the regular form is effected.

THE "Great Bonanza" which occurred in the Consolidated Virginia mine and extended into the California mine, on the Comstock Lode, was discovered, according to official record, in February, 1873, though there is little doubt that the probable existence of a valuable body of ore had been previously obtained through the medium of a drift run in a tortuous manner from the shaft of a neighboring mine. The find was made in Consolidated Virginia ground nearly 2 years before the Big Bonanza was struck in a drift run on the 1200 level of the Gould and Curry mine. In places this ore body was 320 feet in width. It was about 800 feet high and 1200 feet long. It was without exception the most valuable ore body ever discovered in modern times. Others have been found and worked out which were of larger size, but no other has produced so much in gross value or yielded so large a net profit.

CYANIDE MEN are divided in opinion as to the relative merits of sodium cyanide and potassium cyanide, but several prominent practitioners favor the former. By its use they claim the solutions are less liable to fouling; a saving of 20% is effected in freight expense, and its greater purity renders it more efficient. Absolutely pure sodium cyanide is equivalent to about 132% potassium cyanide. It is impossible to state even approximately the requisite proportion of cyanide, zinc and lime to be used per ton of ore, for each local situation involves so many different factors as to be a separate problem. In a broad way, it might be stated that 3¾ pounds potassium cyanide, 1 pound zinc and 4 pounds lime per ton of material treated would be a possible average. In cyanide treatment of slimes this approximation would be modified. Perhaps for the latter 5½ pounds potassium cyanide, 1 pound zinc and 14 pounds lime would be nearer the general requirement. No exact figures could be furnished without accurate knowledge of the local conditions.

THERE is a Congressional law for the incorporation of labor unions, should any of them desire to avail themselves of its provisions. Most of the labor leaders advise against such incorporation. Several trade unions in the different States are incorporated. The question involves complex discussions of policy, of responsibility in the case of suing and being sued, that cannot be even briefly brought out in a "concentrate." It may be said that incorporation would not make the members of a union more responsible than they are at present, except as the union might possess property or money. The mere act of incorporation of a body of men united not for the purpose of pecuniary profit would not ordinarily create any more collective financial responsibility than previously existed on the part of the individuals composing it. Purely as a matter of opinion, it is believed that incorporation would have a steadying influence upon a trade union, and bring its most conservative and cool-headed men to the front. Essentially, incorporation is a privilege, and not a duty.

THE substitution of oil for water in cooling cylinders of gasoline engines does away with any risk of damage to the engine by the freezing and expansion of the water jacket. Small engines can be cooled with oil by replacing the water tank with an ordinary hot-water heat radiator. For engines of medium size a special radiator is used in the form of a vertical boiler containing small tubes open at both ends. The top of the boiler is covered by a cone and short stack into which the exhaust from the engine is conducted to induce a draft through the tubing. The hot oil is fed into the top of the boiler and the cooled oil drawn off at the bottom to circulate back through the jacket of the engine. Large engines require the addition of a small centrifugal pump to keep the oil circulating rapidly. This form of cooler has been successfully applied to engines of over 40 H. P. It cannot freeze, requires no attention, and works well under any climatic conditions. The tank, connections and jackets are sealed air tight, so that no waste of the oil can take place, and the original supply will last as long as the engine.

LEAD can be imported in three ways: In lead-bearing ores, on which there is a duty of 1½ cent per pound on the lead contained; in lead bullion, containing more or less of the precious metals, on which there is a duty of 2⅛ cents per pound on the weight of the bullion, and in refined pig lead, on which there is a duty of 2⅛ cents per pound. The first article—lead-bearing ore—is smelted and refined by the bonded smelter in bond, and, after the lead contents of the ore have been ascertained by the Government assayer, a quantity of lead equal to 90% of the ascertained contents of the ore is locked up in the warehouse by the Government official, which lead has been taken from a general lead pile existing in the smelter, and if this 90% of lead is exported the Government cancels the bond. On the second class—that is, lead contained in lead bullion—the Government locks up in the bonded smelter 90% of the weight of the bullion, and if this 90% is exported the bond is canceled, the same as is done in the case of lead extracted from lead ores. The third class is foreign refined pig lead imported in the shape which can be immediately used by manufacturers.

THERE have been so many methods described for determining the free gold in ores that to give "a new one" is not easy. There is a test, however, not in common use, where say four pounds of ore are crushed to pass a 60-mesh sieve, and panned down in an ordinary miner's pan. With placer gold six pounds are taken for the test as representing $\frac{1}{500}$ of a cubic yard of gravel figuring that 18 feet of gravel in the bank weigh a ton, a cubic yard being thus figured at one and one-half ton. A small piece of gold weighing 123 grains is beaten out so as to form a shallow dish, shaped like a watch glass, and amalgamated on the inner surface. The pannings after having been weighed are transferred to this dish by gently sluicing out the pan through a small funnel held vertically over the dish, the latter being immersed in about an inch of water. The black sand residue in the gold test is then gently agitated or rubbed over the amalgamated surface with the finger. The dish is afterward dried in the sun, or on a sand or water bath, and calculated from the increase of weight. A prospector would want to have a small case with a number of bottles to hold pannings when it was not convenient to make the test at once. Any gold adhering to the dish is of course scraped off before making the next test.

THE problem of transmitting 100 H. P. a given distance requires consideration based upon stated conditions, viz., drop in the line, power wasted in the line, pressure, cost of copper employed, relation between cost of copper and power wasted in transmission, and attendant data. To transmit 100 H. P. 1 mile with 10% drop, if the engine or turbine shows 100 I. H. P., then the dynamo transforms 95% into electrical energy. When 95% enters the line 90% is delivered at the other end. The power delivered at the distant end of the line is 95 H. P., minus 9.5 H. P., 85.5 H. P. The process is not complete as yet, although the power is now at hand, ready for use. It is necessary to transform it again into mechanical energy. This transformation involves a loss of from 5% to 10%, the balance left being the difference between 85.5 — 8.55 = 76.95 at 10% loss in the motor, or the difference between 85.5 — 4.275 = 81.225% at 5% loss in the motor. The efficiency of transmission in any case, with 100 H. P. at one end, and the loss throughout in dynamo, line and motor of 10% apiece, respectively, will be about 77%. The 100 H. P. is thus reduced to 77 H. P. from the beginning to the end of the system. The actual transmission can be readily accomplished if the cost is not prohibitive, but in instances where this threatens to be the case certain means must be employed to raise the efficiency and reduce the cost of installation.

SAN MIGUEL, COLO., cyanide treatment does not vary much, if any, from that of other localities, variance in cyanide practice being a question of ore rather than locality. At the Liberty Bell cyanide works the upper vats are drained under suction, lime being added in the proportion of four pounds to the ton of sands. A weak solution running about three pounds of cyanide to the ton is then pumped on to displace the water retained in the sands. This is washed to waste until cyanide shows and run through the waste solution 2-inch box. At a strength of one pound per ton it is diverted into the weak solution box. After several days of treatment the upper vat is drained and lowered to the vats underneath and the sands washed with strong solution containing six pounds of cyanide per ton. The treatment lasts four days and the strong solution is displaced by weak washes and water until the strength falls to .7 pound per ton, when the vat is ready to sluice out. The strong solutions have a total alkalinity equal to about five pounds lime per ton, of which about half is due to cyanide and half to dissolved lime, so that the solutions are considered to be virtually a saturated solution of caustic lime. The cost of cyaniding 4000 tons per month is about 65 cents per ton; the consumption of cyanide is about one pound per ton of ore treated. The zinc consumption is .035 pound per ton. The extraction averages about 67%, the residues containing about 85 cents per ton.

IN the determination of gold and silver in copper bullion the following is considered to be a good method: The first and most essential point is the preliminary amalgamation of the copper to be assayed. This is effected by shaking one assay ton of the copper with 25 c. c. of water and 5 c. c. of a solution made by dissolving 50 grams of mercury in H NO_3 and diluting to 1 liter. The copper is then treated with 200 c. c. of dilute H NO_3 (475 c. c. to 1 liter), and when the violence of the action begins to diminish, the beaker containing the solution is placed on a hot plate. When action has ceased the solution is heated to boiling and diluted with 150 c. c. of hot water. Any undissolved copper or mercury may be disregarded, as their presence will not affect the results. The solution requires a turbid appearance, owing to the formation of mercuric sulphide, which, by the action of the hot nitric acid, is converted into the insoluble double sulphide and nitrate of mercury. The precipitate is filtered off, the first portion of the filtrate being passed through the filter a second time. The filter is washed and the beaker wiped out with a small piece of filter paper, which, with the paper in the funnel, is dusted with finely divided test lead, and placed in a 2½-inch scorifier, the bottom of which is covered with test lead. From the filtrate the silver is precipitated as chloride, but since silver chloride is soluble, in mercuric nitrate solution, a large excess of sodium chloride is needed, viz., sufficient to convert the mercuric nitrate into chloride in addition to precipitating the silver as chloride. The solution is filtered cold, the paper and precipitate washed, sprinkled with test lead, scorified and transferred to the scorifier containing the gold. The papers are burned, the ash covered with test lead, scorified and cupelled with the usual precaution. In scorifying, it is best to start by heating gently without the addition of borax, the assay being gradually melted, but prevented from scorifying until all indications of spitting have passed; the borax is then added, and the temperature raised until scorification begins.

THE use of any flux beyond what is actually required involves expense in its own cost and in the increased production of slag and expenditure of time, labor, fuel and crucibles consequent upon its addition. Owing to the basic nature of acid treated slimes, a flux of acid character is obviously required. A mixture of ground fused borax, not burnt or calcined, and sand well fills this requirement—the first to occasion fluidity, the second to protect the clay liner. The use of soda as a flux in an already basic material appears unnecessary, the small amount of alkaline oxide needed for the formation of a homogeneous slag being supplied by the borax. Bicarbonate of soda is objectionable, on account of the high percentage of gas it evolves upon fusion. Powdered glass instead of sand has been used, but since the function of the latter is to supply an acid flux and protect the liner, the introduction of such a complex silicate as glass containing unnecessary bases is not wholly advisable. Fluorspar is occasionally used for producing fluidity, especially of sulphates present, but is not deemed absolutely necessary. The effect of smelting a charge with an insufficiency of acid flux and excess of sodium oxide is to produce a corrosive slag, which, on cooling, may be dark and opaque, from suspended base metallic oxides displaced from combination by sodium oxide, and which may even deliquesce on exposure to the air. In dealing with unfamiliar slimes it is considered advisable to run three or four preliminary trials on the actual material to be smelted on a working scale, and under working conditions, with sufficient borax and varying proportions of sand and manganese dioxide and to note on pouring the quality of the bullion produced, the fluidity of the slag as evidenced by its appearance on pouring, and by the freedom or otherwise from gold prills, and the corrosion of the liner. A matte or base looking bullion indicates too little manganese oxide, while too much manganese oxide yields an infusible slag, or one containing much silver. If the proportions and temperature are otherwise correct, addition of borax increases fluidity, while corrosion of the clay liner indicates the need of more sand. Too much sand yields a viscous slag, but, of course, this cause of viscosity can not operate if corrosion of the liner also takes place.

Mining School Graduates.

TO THE EDITOR:—In a recent bulletin of the Department of Mining and Metallurgy of the University of California, Prof. S. B. Christy has presented a discussion relating to the general educational problems now confronting mining schools in this country. The paper, "Present Problems in the Training of Mining Engineers," has attracted considerable notice, due to certain general and pronounced views which it presents, and to the writer it suggests a number of ideas with which he is not entirely in accord. With no spirit of mere criticism or antagonism (for the writer is personally acquainted with Prof. Christy's views and is in accord with many of them), are the following remarks made. The general subject treated is of immense interest to all engineers and all engineering schools, and is not alone of importance to mining and metallurgy.

IS THERE AN OVERSUPPLY OF ENGINEERING GRADUATES?—After giving figures from census reports and elsewhere, Prof. Christy concludes "that there is a legitimate field for not much over 300 mining school graduates each year." The value of this statement must depend upon the point of view. Are mining and other engineering schools to graduate only men who enter the distinctive professions indicated in outline by their college studies? If we assume with Prof. Christy that all graduates are to strictly follow their respective professions, even then the writer cannot agree with his statement as quoted. It does not follow that all graduates will follow by their life work their college course of study, nor is it desirable that they should. A large output of graduates must produce competition, giving the important places to those best fitted, and must force the less adapted ones to positions heretofore filled by the so-called practical and more or less untrained man or out of the profession altogether. Competition must produce greater endeavor and activity and the writer can see in this only good for the profession as a whole. A student, because he has been given a degree, should not be led to believe that therefore he is fit. A college training in mining at best only fits a man for the start and does not insure, of itself, his success. We need a large output of graduates in all the engineering professions in order to procure always the necessary amount of the proper talent.

ENGINEERING SCHOOLS CAN TRAIN MEN FOR GENERAL BUSINESS AND PROFESSIONAL USEFULNESS.—This leads me to state that it is well, for another reason, to have a larger output of graduates from the engineering schools than seem to be directly needed in the strictly, technically professional pursuits; and it further seems to me that engineering teachers, in shaping the college course of study and the requirements for graduation, should remember that the engineering school may have a wider mission and broader sphere of usefulness to the whole community than the developing of but one type of man. A broad engineering training founded upon a sufficiently broad cultural course of study, the two closely blended throughout the student's life, may admirably fit a man for many business responsibilities where his technical knowledge will be of the first importance and assistance to him. American corporations are learning that it is to their interest to select for their directing forces men of business and legal capacity who are also technically informed. Surely no one will deny that many lawyers are handicapped in treating important problems of the day by their lack of personal knowledge of the fundamental principles of technology. I do not mean to imply that everybody should have a technical training, for then would I be going to another extreme, but I do imply that because a man has studied in colleges as an engineer is no reason why he must try to be one. When that training is wisely broad he will be equally fitted to seek his adaptability to one of many spheres of usefulness; and when he is in earnest he will find his place; and therefore I hope that the number of graduates may always be relatively large.

Whether or not there are too many mining or other technical schools and whether they are all of sufficiently and equally high grade is another and very different question, which the writer is not called upon to discuss. What effect the steadily increasing numbers of technical graduates may have upon their average wage, and whether engineering courses of study are sufficiently broad and cultural in their tendencies, are further questions of importance raised by the preceding remarks, but they also do not require attention in this letter.

ELEMENTARY AND FUNDAMENTAL SUBJECTS AND THEIR RELATIVE IMPORTANCE IN ENGINEERING COURSES OF STUDY.—In conclusion I wish to express some opinion regarding what Prof. Christy calls "Fundamental Subjects," because the writer does not exactly agree with him as to the relative values of these fundamental subjects to the different engineering professions; and I venture to speak on this topic because I believe I am not alone in the following friendly criticism of certain statements of the professor's which I herewith give verbatim:

"If we can secure for the American mining student a foundation training broad, deep and thorough in mathematics, physics and chemistry, he needs little else to make him invincible. The mining engineer must have a broader basal training than either the civil or the mechanical engineer, even though he specialize less. Mathematics, physics and chemistry are necessary for all engineers; but for the civil engineer mathematics is fundamental, for the mechanical engineer physics is equally so, while for the mining engineer we must add not only physics, but also chemistry, with the closely related allies, mineralogy and geology."

Before Prof. Christy's bulletin went to press, the writer had the privilege of discussing with its author the meaning of the above quotation, and he realizes fully that for brevity and force of expression the author was obliged to sacrifice some truth. Upon its face the quotation is too severe to civil, mechanical, electrical and sanitary brothers of the mining graduate. It is true that one type of the mining man requires perhaps more chemistry and mineralogy or geology than his brethren, namely, the metallurgist or prospector, but for pure mine construction and operation it is not true. All phases of engineering are sufficiently broad to require a scholarly engineer to be strongly versed in the three so-called fundamental subjects of mathematics, physics and chemistry. The engineer of structures must certainly know his mechanics and the laws of physics, and chemistry bears a vital relation to the manufacture of steel and cement; the sanitary specialist must know his chemistry and bacteriology; the electrical and mechanical devotees decidedly their physics and chemistry. In short they must be well rounded students, and no one can definitely say that they require one elementary subject more than another, and certainly in his life work the student cannot afford to follow such a statement in the selection of his studies and the amount of time he applies to them. Engineers are just like other men in that they generally are not masters of their own destinies. Few men follow the line of work they thought themselves most adapted for or interssted in while at college. I know a number of successful mining engineers who studied only in a civil engineering school. The reverse is also true. Lawyers, after their college days, have transferred their attention to technology with the most flattering success.

These remarks lead me to my final statement, which, I think, may well deserve serious consideration by professors of mining in this country. The statement applies to no particular school; it applies equally and with justice to three schools of mining with which I am thoroughly acquainted, all three of the highest rank; and I have every reason to believe that the statement may be generally applied to most mining schools in this country.

What is a fundamental subject? To me mathematics, physics, chemistry are elementary because they underlie those fundamental subjects with which every designing engineer should be conversant whatever his specialty, whether mining, electricity, sanitation, etc.

What, then, are fundamental subjects for the designing engineer? Those subjects which deal with the physical and chemical properties of materials, the behavior of materials under stress and in the presence of fire and other destructive agencies—in short, which deal with their life and their adaptability to particular designs. Mechanics, a complete study of the strength, elasticity, peculiarities and manufacture of the materials of engineering, and the methods for the analysis of the stresses and the means for the design of the simplest types of engineering structures, are fundamental. Unless a man enters metallurgy pure and simple, he has much need for all of these fundamentals. The mining man who is concerned with the getting of ore out of a large mine, the ore once found, is a structural engineer and should know how to build dams and retaining walls, steel head frames and buildings; he may even want to build a water works and a sewage plant, not to speak of a railway spur. Beside, tunneling and shaft sinking on a large scale are civil engineering subjects, despite what may be said by an opposing advocate. The writer does not intend to decry or limit mining in these statements. That he could not do, for he realizes that the mining engineer has the broadest kinds of problems to solve. But he does mean to say that mine construction and operation are almost always structural problems, and with the present engineering curricula the civil engineering graduate seems to have had for such work the fittest training. How many fresh mining graduates are familiar with the first principles of modern steel construction or the building of a high gravity dam? Their ideas are general, but not quantitative. This explains why civil engineers are often quickly successful in mining fields and why many mining men with whom I have talked agree to these statements. I am not trying to prove that a civil engineer makes a better mine constructor than a mining graduate, for such a position would contradict my first remarks. But I do say that what we want always, as the result of all engineering instruction, is a broadly trained man in his elementary and fundamental studies just because he cannot be sure of his future specialized field. That is why I think that most of our mining schools err in devoting time to chemistry and metallurgy at the almost complete expense of necessary knowledge of structural materials and the design of steel, stone and sanitary structures.

The "Economic Geologist."

TO THE EDITOR:—At last the "economic geologist" has appeared, and the horizon of the miner, and the mining investor, is clearing rapidly. Scarcely a cloud remains to mitigate "the roseate hues of early dawn" of a new and facile era in mining.

A slight feeling of confusion and doubt will have to be confessed upon first meeting the title, and its true meaning was only determined after earnest thought and a process of elimination—a negative process, so to speak. Webster and other authorities were consulted. At the first blush it seemed that the term "economic" referred to the relation, in a matter of business, as between these gentlemen and those who desired their professional services; that arrangements could be made which would be economical for the latter, as it were.

But this idea was eventually dismissed as undignified as pertaining to anything quite as awesome as an "economic geologist," and it was evident that the term conveyed a deeper and subtler meaning. The dictionaries say, "economic:—relating to the management of a household; regulative; family, domestic; frugal, careful; economic use of money or time, etc." The last definition given was puzzlesome for a time, but how could anyone use anything quite as passive to the human conception as geology? We could appreciate that a knowledge of geology could prevent many an error in mining operation, for instance, but the economic geologist apparently uses the geology economically. It is, or has been, with him, a purely domestic, frugal, regulative matter, in which his frugal instincts have been applied.

No: the "economic" is not passive. "Management of household, domestic, careful." In these we must find the true meaning. It can only mean an active participation in the great scheme of the universe, throughout the geologic ages, ruled by the great principle of economy. These economic geologists of to-day are assuredly the reincarnation of the acting committee on geology throughout the eons of the creation. They may be pictured, at that period, as advising against the employment of costly cataclyptic forces to effect a given purpose when air and water currents could be made more inexpensively to do the work by merely rearranging a few mountains, or, similarly, advocating the use of groynes instead of messing around with ruinous dredging, etc. — sort of consulting engineers and economists.

Theirs then, to-day, are the secrets of the deposition of the mineral wealth of the earth, which probably accounts for the ease and assurance with which they make apparently extravagant statements, and define conditions, in a manner totally impossible to the mere ordinary human being, however learned. Their source of information is unquestionably supernatural.

But to the outward appearance they are said to be not altogether unlike the ordinary human animal, and, in order probably to disguise as far as possible their supernatural origin and powers, are similarly said to possess many purely earthly characteristics and weaknesses. Any community having the mineral interests of their district at heart should not fail, as early as possible (for the supply will probably be limited), to secure one of these "economic geologists." When secured, the community could proceed to play Jacob to the E. G.'s angel until the blessing is obtained in the shape of definite information as to where the E. G. and his fellow economists stowed away the better class of ore, locally. MINER.

Rossland, B. C.

Tunnel Expenses.

TO THE EDITOR:—I enclose you a report from my superintendent on the expenses of tunneling with a box electric drill:

RUNNING EXPENSE FOR JUNE, 1905.

179 gallons of gasoline, at 25c	$ 44 75
5 gallons of engine oil, at 80c	4 00
½ gallon of motor oil, at 80c	40
2 gallons of coal oil, at 35c	70
1 pound of compression grease, at 25c	25
950 pounds of powder, at 13c	123 50
1500 feet of fuse, at 65c per hundred	9 75
300 caps, at 75c per hundred	2 25
300 candles, at 2½c	7 50
750 pounds of blacksmith coal, at 1c	7 50
124 feet of air pipe, at 30c	37 20
124 feet of 12-pound track, at 35c	43 40
Hauling supplies	11 78
Repairs	51 92
Incidentals	25 00
Payroll	582 50
Assaying	22 00
Total	$974 40

Made 24 set ups with drill, drilling 1061 feet in 202 holes, breaking 827 cars rock, making 124 feet of headway in main tunnel. Average cost per foot, $7.86. Drilled more holes and less number of feet

than in May. Rock much harder and distance gradually getting farther to run out the rock, therefore more expense. The item of assaying is a new expense this month. Tunnel, 8x8½ feet, and 800 feet in.

E. P. MITCHELL.

Santa Barbara, Cal., Sept. 1.

Placer Mining in Alaska.*

NUMBER V.

DRIFTING AND TIMBERING.—Drift mining, whether the workings are approached by shaft or adit, can be most economically conducted by adopting the system which proved successful in California. The mine is opened by a main tunnel or runway, 6 by 6 feet, which generally requires timbering with logs 8 by 8 inches, 6 feet long, the sets having 5-foot centers. This runway is continued out to the end of the block of ground which it is proposed to work, say from 50 to 100 feet in ordinary Alaska operations. It is assumed that the runway occupies the longer dimension of the ground and approximately the center of the pay streak, say 75 or 100 feet in width. From the main tunnel drifts are run transversely each way to the outer edges of the pay. These generally do not require timbering in frozen ground. Fig. 12

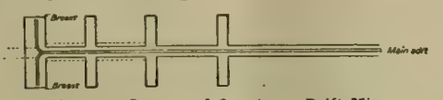

Fig. 12 —System of Opening a Drift Mine.

illustrates the system of main runways and drifts. The gravel can now be breasted out, a face being carried the full width of the pay and the work being continued in two or more of the drifts, as desired, the breasts being always carried toward the shaft or adit mouth. The drifts may be timbered either with sets, where ground is heavy, with single posts and caps in moderately firm ground, or left entirely untimbered, as in solidly frozen ground. Fig. 13 shows

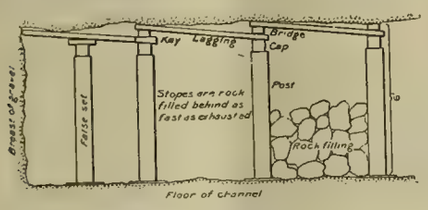

Fig. 13.—Hidden Treasure Drift Timbering.

the manner of timbering closely and rock filling behind when breasting out faces of loose gravel in the Hidden Treasure gravel mine in California. The sketch is made up in part from the report of Ross E. Browne (the ancient river beds of the Forest Hill divide, Tenth Ann. Rep. State Min., Cal., 1890, p. 452) and in part from the writer's own observations. The system of filling behind with quartz stones is impracticable for Alaska mining. Instead of this, timbers should be pulled and the ground allowed to cave. This form of timbering is in use in the drift mines of Solomon hill, Klondike, except that instead of separate base blocks sills are used. Fig. 14 shows a portion of the drift operations which were prosecuted on Solomon hill in the early years of the Klondike exploitation. The plan of the workings is here reproduced by courtesy of G. T. Coffey, manager of the Anglo-Klondike Mining Co.'s operations. The drifting operations in the southern portion of the ground are still in progress.

The main adits are timbered with 4-inch timbers, in sets with 5½-foot centers, at a cost of $1.75 for framing and putting in per foot of tunnel run The entire cost of driving the tunnel 5½ feet high, including steam thawing, excavating, tramming, timbering, and laying track of 12-pound rail, was $6 25 per foot. Transverse drifts were run from the main adits, and the ground was always breasted out in the direction of the adit mouth. The irregularity of the workings in a portion of the ground is accounted for by the fact that a certain amount of unsystematic work had been done previous to the purchase of the ground by the present company.

The ground is solidly frozen and had to be thawed by steam points. The rate of speed with which the work was carried on may be judged from the fact that two men, working a shift in running a straight tunnel after the points had been left in fourteen hours, averaged 5½ feet, including taking out the points, putting in timbers, keeping up the track, and driving in other points to a distance of 5 feet. The average height to which the gravel was taken out in a representative block was 4 feet. The cost of mining was $5.50 per square yard of area worked. In drifting out the ground it was found that three points in a face 6 feet wide, allowed to thaw twelve hours and then withdrawn, the ground being "sweated" twelve hours longer, would thaw all the ground. The sluicing was conducted in the ordinary way of piling up the dump and afterwards caving and hydraulicking with a nozzle into the boxes. The actual working cost of washing was about 18 cents per square yard of area worked.

*Bulletin 263 U. S. Geological Survey.

Production of Antimony in 1904.

Several obstacles combine to prevent the profitable exploitation of antimony ores in this country. These obstacles are set forth by Dr. E. O. Hovey in a report made for the United States Geological Survey on the production of antimony in 1904. In the first place, the reduction of antimony from its ores and its alloys with other metals is a difficult, complex and expensive process, and successful smelting depends upon peculiar conditions. Foreign ores are abundant and cheap. The price of the metal is comparatively low. It is apparent, therefore, that domestic ores do not repay the cost of transportation, and it is not surprising that the production of metallic antimony in the United States from domestic ore during 1904 was practically nothing. Only 25,000 pounds, valued at $396, were reported. Small as was this production, however, it is an advance over 1902 and 1903, when absolutely no domestic ores were reported.

Although the United States has practically no output of metallic antimony from domestic ores, a large quantity of hard lead or antimonial lead is produced here in the process of smelting impure silver lead ores. In 1904 the production of this alloy was approximately 21,752,000 pounds, with an antimony content ranging from 2 13% to 32%, and amounting to about 5,142,000 pounds. Hard lead is used in the manufacture of the several alloys of antimony. Its price ranges about 20 cents per 100 pounds less than that of soft lead. The total amount of metallic antimony obtained from domestic and foreign ores and from hard lead was 3057 short tons in 1904, valued at $505,524.

During 1904 the quantity of antimony ore imported into the United States and entered for consumption was 2,288,518 pounds, valued at $50,414, whereas in 1903 the quantity was 2,714,617 pounds, valued at $54,316, a decrease in quantity, but a slight increase in the average price per pound.

During most of the year 1904 the price of antimony varied but little from 7 to 8¼ cents per pound for Cookson's, 6¼ to 6⅞ cents per pound for Hallett's, and 5⅝ to 6¾ cents per pound for the United States, Japanese, French, Hungarian and Italian brands. Toward the end of the year, however, the effect of the increased demand caused by the Russo-Japanese war began to be felt and prices began to rise. Interest in the market fell off toward the end of December, and the closing quotations were 8¾ to 8⅞ cents per pound for Cookson's, 9 to 9½ cents for Hallett's, and 7½ to 8 cents for other brands.

Antimony is a white, very brittle metal, of laminated or crystalline texture. It fuses at a low temperature and readily vaporizes. It is not used in the pure state, but it forms several valuable alloys and compounds. The most important alloys of antimony are type metal, britannia, pewter and anti-friction metals. Type metal consists, essentially, of lead and antimony, often with the addition of small quantities of tin and nickel or copper. Britannia is a white-metal alloy of antimony with tin, copper and bismuth, and is much used for tableware. Pewter is a similar alloy, but it contains a smaller percentage of antimony than britannia. There are several anti-friction alloys which usually go under the name of babbitt metals. One of these consists of 50 parts of tin to 5 of antimony and 1 of bismuth, but other proportions are in use. The addition of antimony to lead hardens it, and the addition of a small quantity of bismuth gives the alloy the property of expanding at the moment of solidification from a molten state, thus producing a perfect cast from a mold.

Among the useful chemical compounds of antimony may be mentioned tartar emetic, a double tartrate of potassium and basic antimony, which is employed for medicinal purposes and as a mordant in dyeing vegetable fibers; a mixture of antimony trisulphide and antimony trioxide, which forms a flame-red pigment, known as antimony cinnabar, used somewhat in painting; and antimony pentasulphide, which is used in vulcanizing rubber and gives a red color to the product.

The report from which these notes are taken is published as an extract from the Survey's forthcoming volume "Mineral Resources of the United States, 1904." Those desirous of obtaining a copy should address the Director of the Geological Survey, Washington, D. C.

The Ventilation of Mines.

NUMBER V.

WHAT IS ADEQUATE VENTILATION?—The amount of ventilation required in mines to keep the air in such a state of purity as will enable the workmen to maintain good health depends greatly on circumstances, which may be very different in different parts of the State, and even in different parts of the same mine. The object of ventilation is to remove vitiated air and supply fresh, and it clearly depends on the amount of vitiation how much fresh air must be sent in to replace it. Where there is much blasting being done with heavy charges of explosives, or where there is much foul air emanating from the "country," a much larger quantity of fresh air is required than when little blasting is done and foul air is absent. Also when the temperature of the rock itself is high, and the workings consequently hot, it requires a much stronger current of air to be sent through them to cool them down than when the places are naturally cold. It is evident, therefore, that no fixed rule can be laid down to say that any absolute quantity of air is an adequate amount for a given mine, unless such a large amount is specified that it will be quite sufficient for the worst places in it. In other words, an unnecessary quantity must be forced into good places in order to comply with a fixed rule based on what is required in bad places. Otherwise, if for example an average amount for the whole mine, or group of mines, or district is fixed by regulation, the good parts of the workings will still receive more air than is required and the bad ones less than is needed, if the rule is strictly carried out. It is evident, therefore, that rules governing the amount of air to be put into a mine should be based on the condition of its various parts, and not on the number of men working in it, there being no necessary connection between the number of men and the state of the ventilation. When mechanical ventilation is employed, the supplying of an unnecessary amount of air becomes a serious matter from an economic point of view, as the horse power required to increase the ventilation is not in proportion to the increased quantity, but to

its cube, that is, to double a given quantity, eight times as much horse power is needed; to treble it, twenty-seven times; and so on. The cost, therefore, rises very rapidly, and the supply of more air than is necessary is a direct waste of money. The end to be aimed at, therefore, is to put into the mine such a quantity, and to distribute it through the workings in such a way that every man shall receive so much as will thoroughly ventilate the place he is in according to its individual requirements. One place might require 100 cubic feet of air a minute, another 200, and yet another 400. Also a fully sufficient average quantity to give a good supply to every man engaged might be entering a mine, but through improper distribution it might not reach all parts, some places being exceptionally well ventilated and others receiving very little air. Various attempts have been made to fix a definite standard of quantity as constituting adequate ventilation, without great success when the regulation comes to be carried out in practice.

(TO BE CONTINUED.)

Ancient Gravel Channels of Calaveras County, California.

NUMBER II—CONCLUDED.

Written for the MINING AND SCIENTIFIC PRESS by W. H. STORMS.

The Mokelumne Hill channel system is the most complicated of the several systems occurring in this county. Nine distinct channels have been identified by the writer in this district, each of separate age, and each having its own peculiarities and characteristics. The channels range in elevation through a distance of 250 feet. That is, the lowest of these old river beds is not less than 250 feet below the highest channel in the vicinity. Relative altitude is not an indication of the respective geological age of these channels, but, generally speaking, the higher channels are older than the lower ones, and in some cases the older streams have been crossed and cut out by the later rivers, and what is true of the Mokelumne Hill system in this respect applies to all of the ancient river channels of California.

The earliest channels of the Mokelumne Hill system are high above the neighboring ravines and gulches, and these have been exposed at numerous places, as on French hill, a mile northeast of Mokelumne Hill, and on the north end of Stockton ridge, in Happy valley and elsewhere, but the latest channels have cut their ways down into the bedrock, and are considerably below the level of the drainage of the modern streams. The channels of intermediate age are often found to have been cut, for most part, in the lava which caps all of the ancient channels. One of the most recent channels of the Mokelumne Hill system is what is known as a volcanic channel—that is, composed almost wholly of volcanic cobbles, boulders and other debris, often forming a cemented agglomerate. The latest of all the channels of this system is that known as the Old Woman's Gulch channel, and is 250 feet lower than the Corral Flat channel at Mokelumne Hill, but since that ancient stream was formed and filled by volcanic mud and an agglomerate of andesitic material, the Mokelumne river has cut its channel down through hard greenstone and other crystalline rocks, at least 500 feet below the ancient stream under Old Woman's gulch. This fact in itself indicates an enormous lapse of time since these old rivers were living streams.

The channels lying high up on the hills and ridges, and which were easily attacked by the miners, have, to a great extent, been worked out, but the deep streams lying below the drainage have offered some obstacles to the development of mining operations, the principal one being the abundance of water usually encountered in these deep streams. Although the canyon of the Mokelumne river affords abundant opportunity to cut under the old channels, they nearly all flow away from the river, and it is not generally thought the results of mining will justify a tunnel of sufficient length to reach the old streams at a point where any advantage would be gained. Thus a tunnel driven from the canyon of the Mokelumne river to reach and drain 2½ miles of the Old Woman's Gulch channel must be at least 3 miles in length, an undertaking too expensive to be given serious consideration until something more definite is known concerning the probable result of such an enterprise. There are two leads in the Old Woman's Gulch channel—a bedrock channel, and a later higher channel having for bedrock a volcanic ash, indicating two periods in the formation of this stream. This is a feature not uncommon with a number of channels in this county. In some instances the upper leads have been worked at considerable profit, chiefly, however, by hydraulic methods. It is also known that a large portion of the Chile Gulch channel still remains intact, but the same disadvantages—abundance of water and uncertainty of results—handicaps exploration by means of long tunnels driven through bedrock. The accompanying sketches illustrate the relation of these ancient streams to the modern drainage.

The high channels have, to a great extent, been worked out, though doubtless there still remain remnants of these which would pay handsomely could they be discovered. It must be remembered that these older streams were generally smaller and more sinuous in their course than those formed later, and that these earlier streams were intersected at various places by the later streams. As these old river beds are for the most part buried beneath 200 to 500 feet of lava, it is not an easy matter to pick up a stream which has been cut by a later one, when there may be a breach 1000 feet or more in width intervening between the worked out end and its possible continuation. In some instances the later stream has cut into the earlier one at a low angle and for some distance, at least the two coincide in the direction of their flow, thus making it far more difficult for the miner to pick up the continuation of his river bed where once cut out. In the early days when these high channels were worked extensively claims were small—16 feet square in many cases in the Mokelumne Hill district, particularly on Stockton ridge. The channels were from 250 to 350 feet deep under the lava cap and numerous small circular shafts were sunk to find the channel, and although sunk fifty years ago these shafts are still open. In order to work to advantage many small claims were consolidated and in this way rich gravel deposits were worked. All claim owners worked as rapidly as possible to remove the gravel before those owning neighboring claims could appropriate a portion of that which did not belong to them—a practice not at all uncommon in those days, and conflicts were numerous and sanguinary. Little attention was given to the geology of these deposits, and judging from the cement literature of that day they had the most vague and erroneous ideas of the origin and character of the old rivers.

The respective courses of the several ancient rivers is shown on the accompanying map, which was made from data carefully obtained. There are, as previously stated, some uncertain points which still remain unsettled. One of them is the probability of a channel occurring on the east side of Chile gulch about a mile south of Mokelumne Hill. Another interesting and much disputed point is the course of the channel rising in Section 1, T. 4 N., R. 11 E. This has two branches flowing northward with heavy grade for half a mile, when it flattens, and for more than a mile the grade is nearly flat. It is cut out by the Old Woman's Gulch channel, but work done in the Chile Gulch channel about ten years ago at this place discovered a narrow channel flowing westerly, nearly opposite the point where the stream in question is cut by the later Old Woman's Gulch channel, and it is believed by the writer to be the continuation of this small river. It is undoubtedly cut by the Concentrator channel a little farther west.

The Concentrator and Duryea channels came from the direction of Volcano and Rancheria, in Amador county, passing near the town of Jackson, and there being intersected by the Mokelumne River canyon. A remnant of these channels appears on the high hills between Jackson and Stockton Hill, and they then pass under Stockton ridge, as shown on the map.

The Fort Mountain channel system rises in the region north of Calaveras county and flows southwesterly toward San Andreas. This system is joined near this town by the system of old veins coming from the direction of Murphys. In the early days of placer mining in this county there were a number of noted places where large amounts of gold were obtained for comparatively little labor; these were at Mokelumne Hill, San Andreas, Murphys, Cave City and Vallicita. In each of these instances the gold came mostly from the ancient rivers at places where they had been cut by the modern gulches and where the gravels were easily accessible.

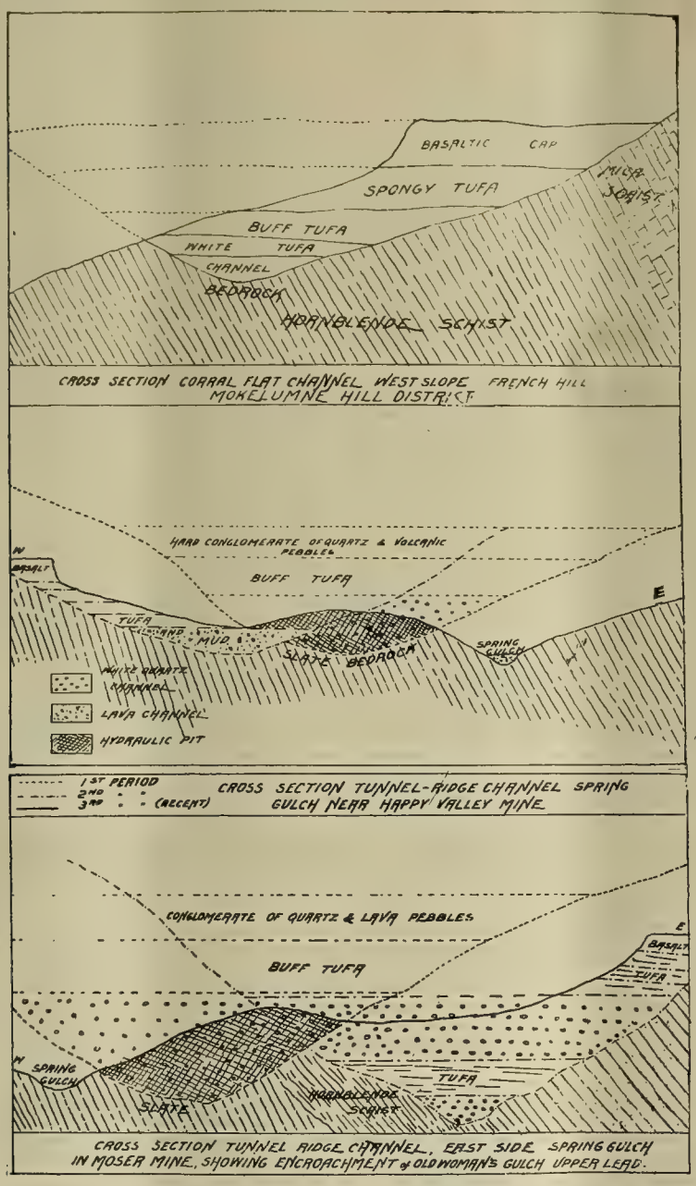
CROSS SECTION CENTRAL HILL CHANNEL ½ MILE ABOVE VALLECITO WIDTH OF UPPER LEAD 700-1000 ft

In a number of instances the old river beds, where favoraby exposed, were hydraulicked, and large profits resulted. In others the gravel was drifted and sluiced with good results. At Vallicita a drain tunnel was run under the flat and many thousands of dollars taken from a comparatively small area. Similar conditions were found in the vicinity of the place known as Cave City, at that time a settlement of several hundred miners, now only a memory, with two or three dilapidated houses.

At San Andreas most of the gold was obtained by drifting the rich gravels. Water was troublesome but was handled by long, though shallow, drain tunnels. In one instance the owner of a claim known as the Plug Ugly required a drain in order to work his mine. Such a drain would naturally prove a benefit to the claims lying above on the same channel, so he solicited financial aid from these claim owners, which was refused. He ran the drain himself, worked out all of his ground but a few feet and then stopped, leaving this nearly impervious barrier to dam up the water on to the claims above. They remained idle for years, for, contrary to expectations, the clay in the gravel held the water back and the mines could not be worked unless the drain was continued or power-

ful pumps put in to control the water. After several years a compromise was made and by paying a stipulated sum the drain was run and work was continued.

It would be expected that these ancient channels would have been largely worked out many years ago, but such is not the case, for there still remains a large amount of unworked ground in the channels of this county. Not only is this a fact, but there is more activity in this class of mining in Calaveras county at present than before in many years. At Douglas Flat, San Andreas and Mokelumne Hill particularly, active mining is being done by a number of companies, beside which there is a large amount of prospecting and development in progress. Although there are 40 miles of ancient unworked channels in this county, the great drawback to the more vigorous development of these deposits probably lies in the fact that by far the greater portion of the ground is covered by agricultural patents. It seems strange that agricultural patents could be obtained on land of this character, but it has been accomplished, and in some instances, at least, the means to defray the expense of obtaining the patent and to pay for the land was secured by working the gravel beds for the gold they contained.



Semi-Electrolytic Process of Gold Assay.

In the ordinary process of assaying by cupellation and parting, the former operation is accomplished with a loss of gold, while the latter is incompetent to remove the last traces of silver. When the whole assay is experimentally carried out on absolutely pure gold, mixed with absolutely pure silver, the final error is a constant one, and the proper allowance may be made. But in practical work other metals besides silver and lead are liable to be present (although in small amounts), and by their difference in specific gravity they cause the results to vary. A. Bock finds that if a plate of gold be placed as anode in an electrolytic bath filled with nitric acid of the specific gravity 1.2, opposite a platinum cathode, the liquid rapidly becomes opalescent and opaque. On interrupting the current, the electrolyte clears again and a precipitate of gold is deposited, but the cathode remains uncoated. The action is, therefore, mechanical in its nature; the anode is disintegrated by the evolution of oxygen and the current of electricity, without being actually dissolved. If, however, the cell contains water, but be faintly acidified with nitric acid, the electrolyte does not become cloudy, the weight of the gold remains unchanged, while the silver and all other soluble metals in the anode (except lead) are deposited on the cathode or dissolved on the liquid. Bock's process of gold assay depends on this phenomenon; and the following example, which shows its accuracy, also indicates the method of carrying it out in practice. Two pieces of fine gold, weighing 500 milligrams, were each melted with 1300 milligrams of silver in previously warmed graphite crucibles. After cooling, the buttons were hammered, rolled and melted once more to ensure uniformity of composition—the yield in each case was exactly 1800 milligrams of alloy. The second buttons were rolled out, parted in the usual manner, then immersed in a bath composed approximately of 1 volume of nitric acid (sp. gr. 1.2) diluted with 6 volumes of water, and submitted to an electric current, the strength of which was "about that employed in copper analysis." After ten minutes, the platinum vessel containing the rolls of gold were rinsed out with water, placed in boiling water for a few minutes, again washed, and the gold dried and ignited in an earthen crucible. The total weight of metal recovered was exactly 1000 milligrams. When the legal alloy of 900° fineness is being examined, not more than 900 milligrams of silver should be added to each 500 grams, lest the pieces of gold become too porous and break; but the process is generally as accurate as in the case of fine metal. In melting this alloy, it is well to use nearly new plumbago crucibles, so that the carbonic oxide produced may prevent oxidation of the copper. As lead is not dissolved by the above process, when this metal appears in the pieces of gold, they must be treated in a fresh bath of nitric acid with the direction of the current reversed; but under no circumstances must the change of polarity be made in the one platinum dish. The new method occupies practically the same time as the old one; it is, taken altogether, a little cheaper, and it forms an easier way of preparing samples of pure gold to act as standards.

The New Ingersoll-Sergeant Plant at Phillipsburg, N. J.*

The new plant of the Ingersoll-Sergeant Drill Co. at Phillipsburg, N. J., is completed. It is a large and modern establishment devoted to the manufacture of rock drills, air compressors and pneumatic tools. The design of this entire plant, to the minor details of floor arrangement, was the work of the Ingersoll-Sergeant Co.'s own engineers and draughtsmen. The intent has been to obtain maximum efficiency with minimum expenditure of time, power and manual effort.

There are twenty separate buildings, each of structural iron, brick and concrete construction. While each is a unit complete in itself, the several shops are so arranged as to form a single unit, which is capable of further extension along the original plan.

Within and between the buildings dozens of Pawling & Harnischfeger traveling cranes (which have helped to make Milwaukee famous) are in readiness. The foundry alone has ten of these cranes and here, as in all other buildings, the cranes can control the entire floor area, whether in the main building or in the wings.

The facilities of the plant are such that castings from the foundry are advanced from one process to another almost automatically, and each part is so accurately constructed as to be interchangeable.

In the center of the group of buildings and connecting with each is a subway of concrete and steel construction, which carries piping and wiring for compressed air and electric power transmission, water supply, lighting and hot water heating.

Everything in this subway is on the unit system and can be altered or enlarged as required. The piping is bracketed to the walls and the wiring enters the various buildings through multiple conduits. In the shops electric plugs—each with its steel cover-plate—are conveniently located near the supporting columns, so as to connect readily with the many Crocker-Wheeler direct connected motors with which lathes, drills, planers and other shop tools are run. Compressed air connections for pneumatic tools are made in a similar manner at convenient points.

The shop heating system, whose main stem also traverses the subway, is supplied by two De Laval steam turbine two-stage centrifugal pumps, each of 50 H. P. The boiler which supplies steam to these is equipped with Foster superheaters.

In the engine room of the central power plant are an Ingersoll-Sergeant-Corliss compound condensing two-stage air compressor and an Ingersoll-Sergeant class H compound condensing duplex air compressor; three 300 K. W. Crocker-Wheeler direct current generators, each driven by 450 H. P. Cooper-Corliss compound engines, and a 100 K. W. generator driven by a 150 H. P. engine, both of the types last mentioned.

The boiler room has a capacity of ten boilers, arranged in double batteries, which will give a total capacity of 2500 B. H. P.

The rock drill department has a floor area of 125,000 square feet. Hundreds of workmen are busy at dozens upon dozens of planers, lathes and machine drills, while thousands of parts, from the rough casting to the finished jacket or piston, are piled in orderly rows convenient to the workman's hand. Everywhere are jib and traveling cranes, and none of them seem idle. Motor drives and line shaft drives are arranged on parallel systems, designed to give the greatest efficiency in the least possible space consistent with good results. This rock drill building is of one story construction with saw-tooth roof arrangement, thus insuring an equality of light everywhere in the shop, and an almost perfect system of natural ventilation.

Near at hand but in a separate building is the drill testing department, fully equipped to give the drills a practical test through all of the varying conditions of actual operation. Every drill turned out by the company has to pass through the hands of the experts in this department, and any defect in construction or irregularity in operation marks the drill at once for thorough overhauling. Whenever a new type of drill is designed by the firm, as in the case of the "Little Jap" drill recently put upon the market, tests covering a period of months are made at the company's quarry, near the old plant at Easton, Pa. These practical tests are of course supplemented, in the case of all drills shipped to the trade, by the severe "service tests" in the department just described.

The air compressor erecting shop is an interesting feature of the plant. In this the complete compressors are subjected to no less severe tests than those which the rock drills receive, and the operatives are men of many years' service and experience with the company. The compressor erecting shop is 325 feet long and 45 feet high. Connected with this shop are the compressor manufacturing departments, each situated in a wing of the main building. As in the rock drill shop, a noteworthy feature is the large number of parts which are going forward to completion.

The foundry building is 500x160 feet, and has an equipment of four cupolas and eight coke ovens,

*See illustrations on front page.

besides a full complement of mammoth traveling cranes. The cupolas range in size from 68 inches to 86 inches, and each is supplied with a motor driven blower set.

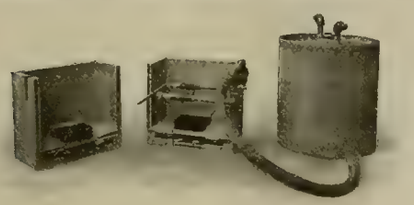
The foundry floor is 18 feet below the main plant level, thus facilitating the handling of coke, pig, sand, scrap, etc., for the storage of which huge bins are conveniently located under the standard gauge railroad spur, which adjoins the foundry building on a level with the main plant. In the shop yards are over 5 miles of standard gauge and "industrial" track for transportation of material between the buildings.

The pneumatic tool department, now at the old plant at Easton, Pa., will shortly have a building of its own at the new works. This branch of the company's business has grown rapidly of late.

Already a considerable settlement is springing into existence around the new plant, and many of the 2000 or more operatives will doubtless build or buy in this vicinity, to be near their work.

McGill Lubricator.

Herewith is illustrated the McGill lubricator, com-



posed of a wooden box 15x15 inches in the clear, made in two sections, to be easily separated and put together. In lubricating flat hoisting cables, the box is taken apart and placed over the mouth of the shaft on two pieces of wood, the rope being allowed to pass through the center of the box. The oil is kept in a galvanized storage tank and is forced out by means of compressed air through small apertures on each side of the rope, thereby lubricating the under as well as the upper side of the rope at the same time. In oiling, the rope is always lowered. A few inches below these apertures in the box there are two brushes, one on either side of the rope, which cleans the rope of any surplus oil. The waste or surplus oil is caught and used over. By the use of this lubricator the manufacturers claim it is a saving of time as well as in oil. It is made and sold by the Hendrie & Bolthoff Manufacturing & Supply Company, Denver, Colo.

Treatment of Copper Rock at Quincy Mills, Hubbell, Mich.*

Written by C. K. HITCHCOCK, E. M.

The rock treated at the Quincy Mills is a moderately hard amygdaloid, coming from the Quincy mine, which is working upon the Pewabic lode. It contains at present about 1½% of native copper and varying amounts of quartz, calcite, epidote and the zeolites filling the amygdules. Since the specific gravity of the copper is far in excess of any of the other constituents of the rock, it will be seen that the difficulties in milling arise more from the low grade of the rock than from the nature of the separation. As is the case in all low-grade milling operations, a fraction of a per cent of the valuable mineral, more or less, in the tailings represents a relatively large variation in the amount saved compared with the original amount in the rock, and, of course, means much in the profits of the operation.

During recent years efforts have been made to reduce, as far as practicable, the loss in the tailings. Without going into details concerning the experiments and tests in this line, the method of treatment will be described as it is to-day. It will suffice to say that the efforts to reduce the loss in the tailings have been made in three directions:

1. In obtaining the most economical machines for treating the material.
2. In re-treating material heretofore sent to waste.
3. In making the tailings poorer by increasing the amount of the heads, thereby decreasing the richness of the same.

After experimenting for several years, the result at present is: The substitution of Wilfley and new standard tables for the old two-deck revolving round tables; the separation, grinding and further treatment of a middle product from the roughing jigs, and the increasing of the amount of slime copper (No. 3 grade), at the expense of its richness, to a point where the increased smelter charges offset the saving of copper. Besides these, of course, changes of detail in treating the material have been made. The saving of float copper, however, still remains to be effected. The float copper is not due, as in the case of friable ores, to the crushing operations so much as to the shape of the piece. It does not matter so much how small the particle, so long as it is comparatively thick and compact. But the copper occurs in the mine in many places in thin sheets, much like foil, and this, when broken up small, will float off in the wash water, in spite of all care taken. The production of fine copper in stamping, however, has been greatly reduced by introducing a mortar discharge, by means of which copper which has been freed from rock, and which is too large to pass through the mortar screens, is taken directly from the mortar while stamping continues. Formerly this copper remained in the mortar, subject to the stamping which it could not escape. Frequent shutting-down of the stamp head was then necessary to allow for cleaning the mortar, which is now greatly reduced, resulting in a saving of time. Improved facilities for shipping the mineral to the smelter might be added to complete the list.

The two mills are on the shore of Torch lake, Houghton county, Mich. The older, or No. 1, mill contains five stamp heads, and the new one, No. 2, contains three. Although the treatment in No. 2 mill in particular is described here, the method used in No. 1 differs only in minor details. No. 2 mill measures 217x132 feet in size, of steel frame, and is situated on a side hill, so that nearly all material is handled by gravity. The storage bins extend the entire length of the building and are 22 feet wide and 26 feet deep at the front, holding when full about 2000 tons. The bottom was constructed by filling in poor rock until it took the natural slope from the back to the front, and by then laying a plank covering over this filling. The foundations of the stamp heads are built up of concrete and timber from the rock foundation. Power is furnished by a 16x36-inch engine. Water is supplied at the rate of 16,000,000 gallons per twenty-four hours by a vertical, triple-expansion pump of E. P. Allis make, and is maintained at a constant head by pumping it into an open iron supply tank, provided with an overflow. Formerly the water was furnished to each mill by a separate pump; but now the two systems are connected, so that a break-down of either pump will not necessitate a shut-down of either mill.

The copper rock, having passed through 4-inch grizzlies or through 10x20-inch jaw crushers at the mine, is dumped directly into the bins from the railroad cars. About 3350 tons per day are treated by the mills, which represents the output of the mine, exclusive of such masses of copper as are cut up underground, and such smaller masses as may be easily cleaned in the rock houses at the mine. The rock is then fed from the bins to the stamps by means of a chute. These stamps were all furnished by the E. P. Allis Co., but a Nordberg mortar has been substituted for the third head in No. 2 mill. They make 100 strokes per minute, at 120 pounds steam pressure. At present each head is stamping over 500 tons of rock per twenty-four hours, which is crushed until it will pass through the ⅝-inch mortar screens. Such pieces of copper, however, as can not be reduced sufficiently in size to pass through the screens are from time to time removed directly from the mortar by means of the mortar discharge. This is done merely by allowing the pieces of copper to pass through an opening in the mortar against a stream of incoming water strong enough to prevent the discharge of the smaller pieces of rock. The copper thus obtained is called No. 1 grade of mineral. Such material as does pass through the screens is conducted over a hydraulic classifier, which consists of a square box attached to the launder in such a way that the material must pass over a strong rising current of water. Whatever is heavy enough to pass down through the classifier against the stream of water is also collected as No. 1 mineral. The other portion passes into trommels, and those pieces which are too large to pass through the trommels—that is, over ¼ inch in diameter—are returned to the stamp by means of a bucket elevator to be crushed finer. These trommels are of perforated sheet iron with ¼-inch holes and are 5 feet 10 inches long by 2 feet 3 inches in diameter at the small end and 3 feet 5 inches at the large end. They make fifteen revolutions per minute. The material passing through the trommels is conducted over other hydraulic classifiers which separate out, as above described, No. 1 mineral and allow the remainder to go to the roughing jigs. There are two trommels to each head and each supplies material to three sets of four jigs each, each jig having two sieves and each sieve being 2x3 feet in size. The jigs are all run at 133 strokes per minute with a ¾-inch stroke.

The plant is so arranged that each set of four jigs receives the same grade of material, and the supply to each can be regulated by a gate placed in the launder; but the material treated by the individual jigs of each set is classified by being fed against a rising stream of water, so that the first sieve of the first jig, being 8 mesh, receives the coarsest material; the second sieve, 10 mesh, less coarse; and so on with the first and second sieves of the second jig, which are respectively of 12 and 14 mesh and receive finer and finer sizes. The third and fourth jigs of each set treat the overflow from the first and second jigs respectively, and the sieve in each case is 2 meshes per linear inch finer than the sieve whose overflow it treats. Whatever does not go to the roughing jigs is considered slime and passes on through an overhead launder to the settling boxes, which feed the slime tables. The tailings of the third and fourth jigs of each set go to the wastes and launder.

A middle product is obtained from both sieves of the third jig of each set—that is, the jig treating the overflow from the jig which treats the coarsest material. This middle product is drawn off through a ¾-inch pipe entering a little above the sieve, an operation which is accomplished by admitting air through another pipe at this point. This material runs in a launder to a Chilian mill in mill No. 2 and to a Huntington mill in mill No. 1, where it is reground and treated as will be described later. As the jigs run with considerable suction, a large amount of hutch work is obtained. This is treated on the finishing jigs and tables.

The finishing department consists of two sets of three 2-sieve jigs and two Wilfley tables to each head. These jigs are of the same size as the roughing jigs, but are of a more recent design, in that the motion is imparted to the plunger by means of an eccentric, instead of the rocker arm, whereby the motion is more easily regulated. They are run at 165 strokes per minute, with a ⅝-inch stroke. The material coming to each set passes over a hydraulic classifier, the overflow from which feeds the two sieves of the first jig, the same as in the case of the roughing jigs. Stuff too fine for treatment on the jigs passes into a settling box, whence it is fed to a Wilfley table. The overflow goes to waste. Whatever goes through the hydraulic classifier, together with the hutch work from the first finishing jig of each set, contains all the silver that is saved. Formerly No. 1 mineral was picked over by hand for silver, but this is now found not to pay.

The overflow from the first finishing jig is treated by the second jig, and the overflow from this, in turn, is treated by the third jig. The overflow from this last goes to waste. The hutchwork of the second jig is collected in a box and is called "No. 2 mineral." That from the third jig is too poor for a finished product and is re-treated on the slime tables. The concentrate from the Wilfley tables mentioned above is called "No. 3 mineral."

The slime department consists of nineteen Wilfley tables, a set of jigs and four new standard tables. The Wilfley tables are of the standard size and treat twenty-five tons of material a day. The new standard tables are used to furnish the finished product, while the Wilfleys discard the tailings. As stated above, the material coming to these tables is stuff that is too light for treatment on the roughing jigs. Before reaching the tables it is received in six settling boxes—two to each stamp head. These boxes are 11 feet by 5 feet 6 inches in size, rectangular in plan but pointed in elevation, with a depth of 3 feet 9 inches. They are elevated about 10 feet above the floor and the tables are fed by small closed launders. Each settling box feeds three Wilfley tables. The tailings from the tables go to waste, but the heads from each group of six Wilfley tables are collected and by means of a centrifugal pump are sent to another settling box, from which a new standard table is fed. The heads from these new standard tables are collected and are called "No. 3 mineral" or "slime copper." The tailings are returned to one of the first-named settling boxes for retreatment on the Wilfleys.

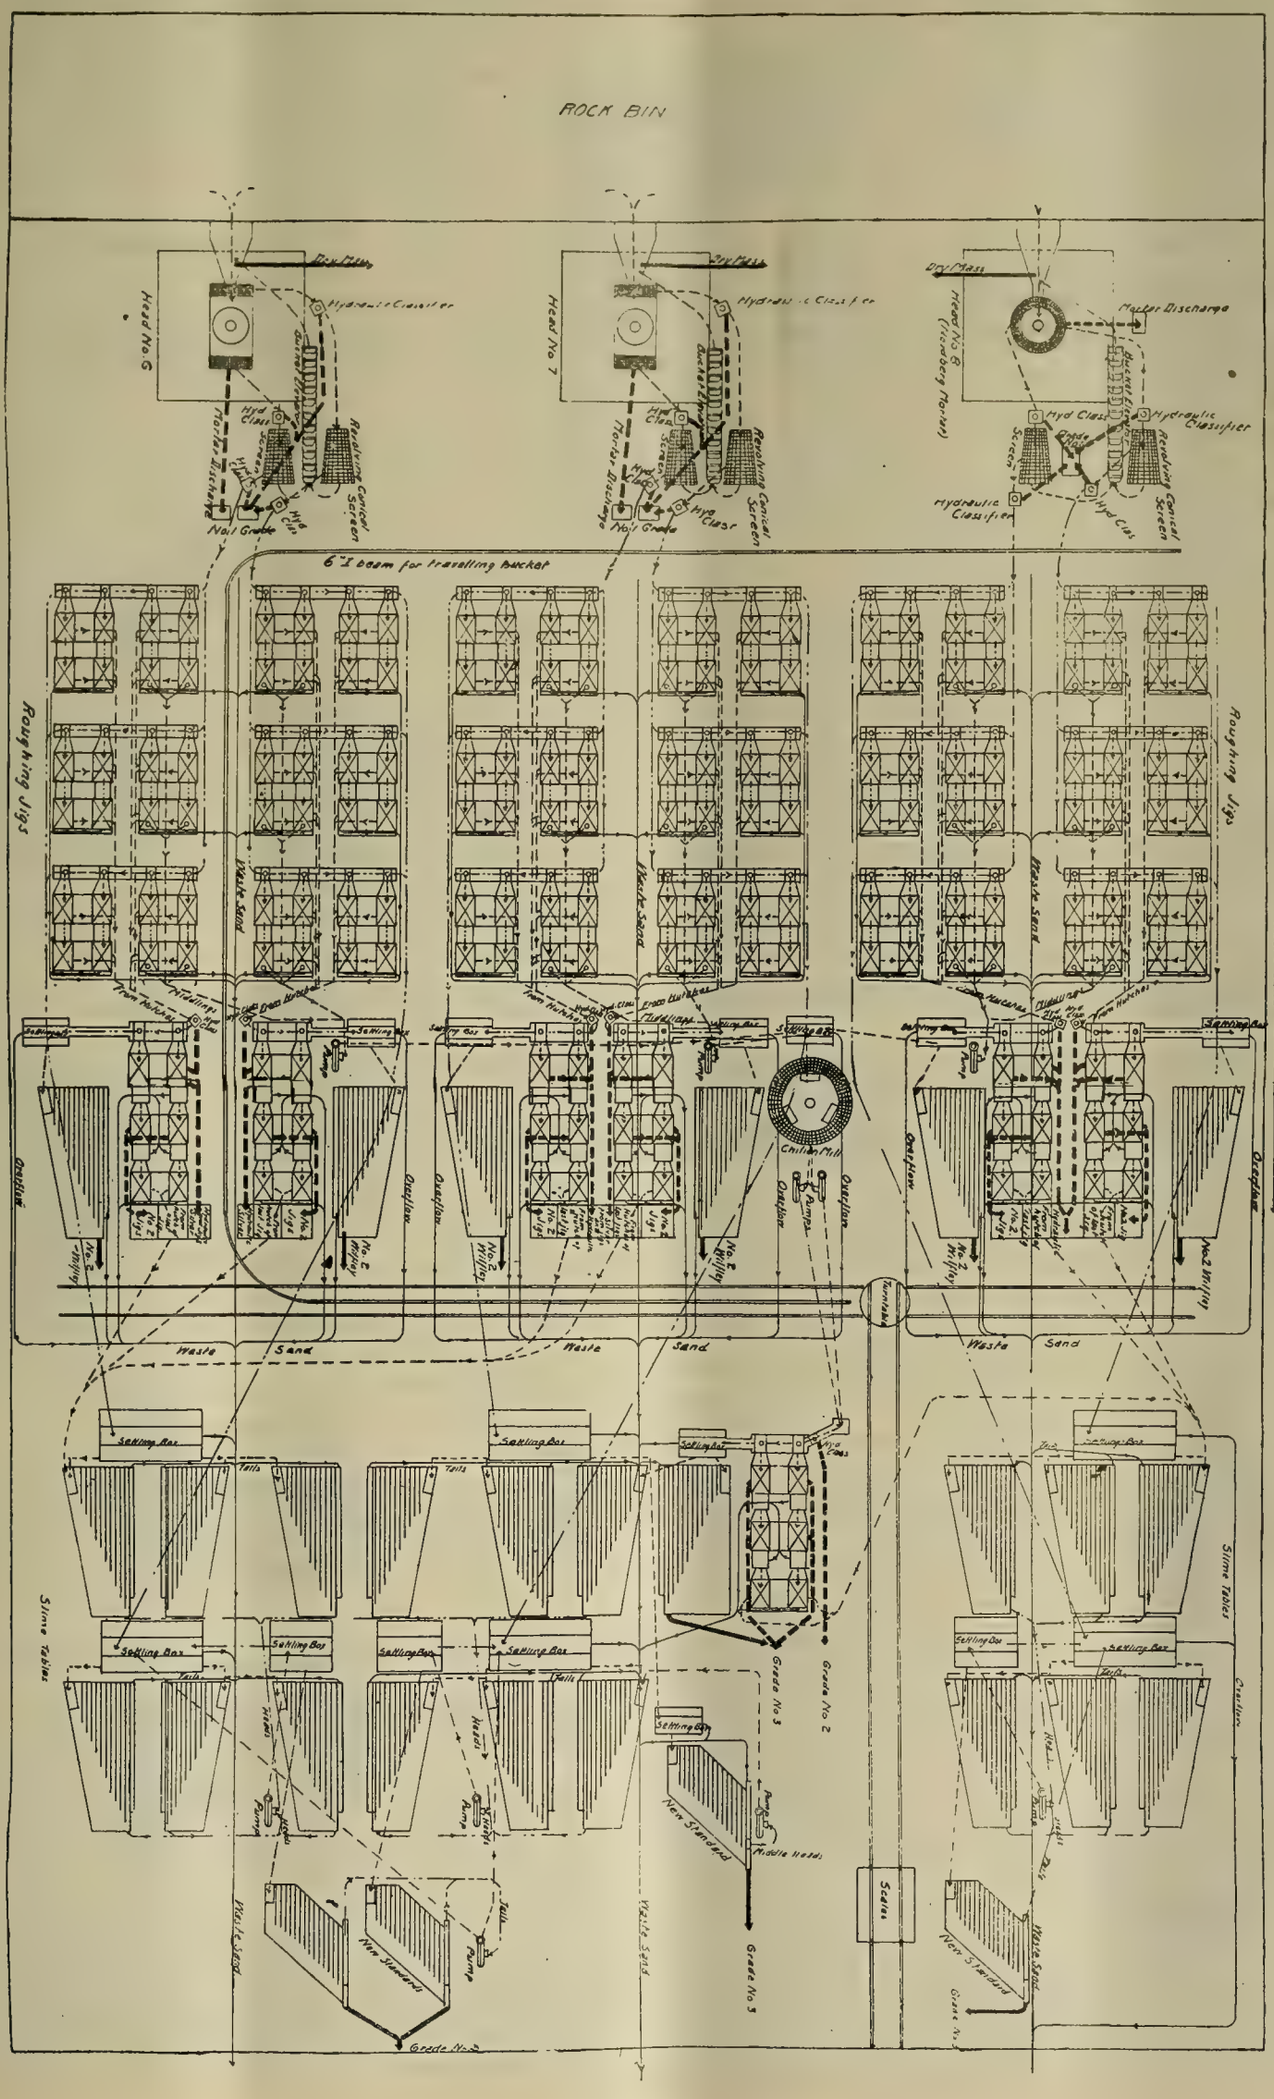
The Chilian mill mentioned above as treating the middle heads from the roughing jigs has a 6-foot mortar with 10-mesh mortar screens. It is run at twenty-five revolutions per minute and treats sixty tons of material per day. The crushed material passes from the grinder over a hydraulic classifier to a set of three 2-sieve jigs, precisely similar to the finishing jigs.

The product of the classifier is "No. 2 mineral," the hutchwork from the first two jigs is "No. 3 mineral," and the hutchwork from the last jig is re-treated on the slime table. The fine overflow passing the jigs is treated on a special Wilfley table, from which the heads are saved.

Until recently the different grades of mineral were packed in separate barrels, as has long been the custom in the Lake Superior region, and shipped to the smelter by rail. This is a primitive and expensive method of shipping mineral where any considerable amount is to be handled and has now been abolished at the Quincy mills. The mineral is shipped in bulk in special cars by rail to the smelter, which is situated a short distance east of Hancock, on Portage lake. The different grades are now collected from the concentrators in a bucket which holds 400 pounds and which is suspended from a traveler running on a 6-inch I beam overhead. The contents of the bucket are emptied into small cars holding from 2½ to 4 tons each, depending on the grade of mineral. The cars enter the mill on the ground floor, where they are filled and made up into trains which are hauled by an electric locomotive—like those used underground at the mine—to the old mill, where the contents are dumped into bins. In the old mill the collecting bucket empties directly into the bins. These bins are large enough to hold two days' supply and are divided into compartments for the different grades of mineral. The empty mineral cars are brought in and spotted on a 54-foot set of railroad scales, the compartments of which correspond to the compartments in the bin. Each grade may now be run separately into the cars without any necessary movement of the latter, and at the same time the amount of mineral is

*School of Mines Quarterly.

FLOW-SHEET OF No. 2 MILL



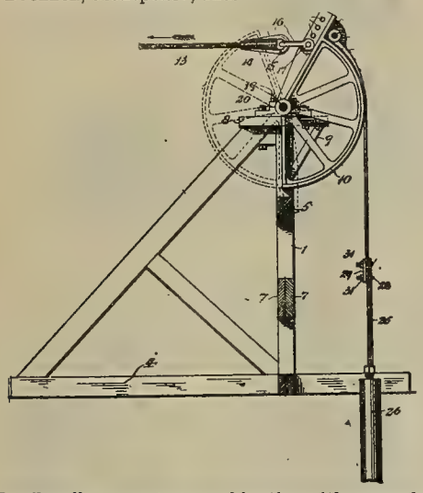
weighed directly or by difference. A further advantage is secured over the old barrel method in that there is a greater elimination of moisture before the mineral reaches the smelter. When once the mineral was barreled it lost but little moisture, and in winter it generally froze so that a great number of barrels were destroyed getting the frozen mineral out. Now the moisture drains while in the bins and in the cars and is exposed to the cold only while in transit to the smelter. At the smelter bins have also been constructed where further drainage takes place before the mineral is charged to the furnaces.

Mining and Metallurgical Patents.

PATENTS ISSUED AUGUST 29, 1905.

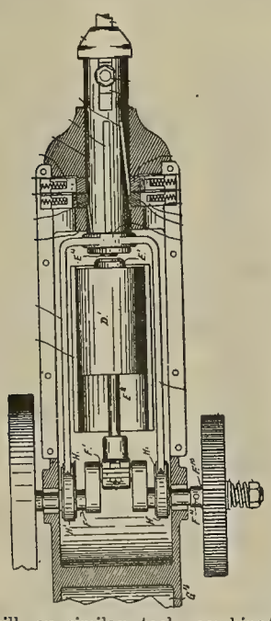
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

OIL WELL PUMP ATTACHMENT. — No. 797,672; S. Drennen, Montpelier, Ind.



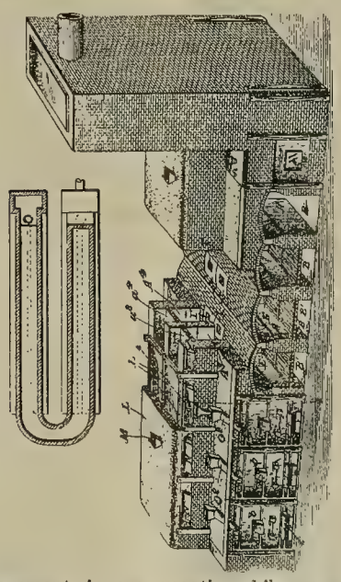
In oil well apparatus, combination with pump shaft, mutilated pulley periphery of which is less than semicircle and tangentially situated relatively to line of shaft of pump, lugs formed integral with pulley at top end thereof, flexible connecting strap hingedly connected at upper end to lugs, and removable connecting coupling situated at bottom end of strap, of reciprocating means, lever integral on and situated at one side of mutilated pulley, extending radially from center of and beyond periphery thereof and provided with series of clevis-pin-receiving holes arranged at intervals or gradations along length, cable, clevis and clevis-pin connecting clevis and lever, reciprocating means connected to cable, and suitable triangularly formed supporting frame comprising vertically extending forward portion, backward or rear inclined portion and bottom connecting or sill portion for supporting pulley.

ROCK DRILL.—No. 798,416; M. C. Jackson, Denver, Colo.



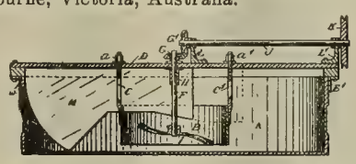
In rock drill or similar tool, combination with eccentric shaft, of hammer, drill bit distinct from hammer, but arranged to be acted on thereby, and suitable connections between eccentric shaft and hammer, and between eccentric shaft and drill bit for simultaneously imparting to hammer and bit reciprocating movement.

ORE ROASTING KILN.—No. 798,524; J. McNab, Catonsville, Md.



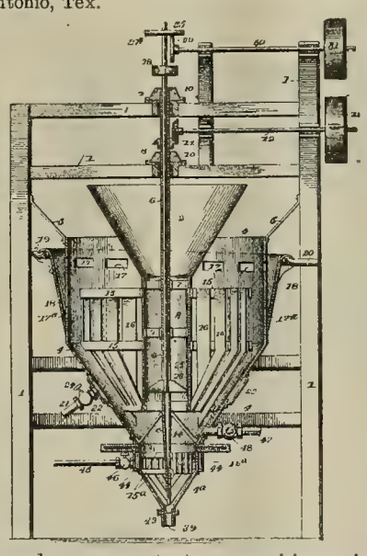
Improvement in ore roasting kilns comprising series of fireplaces arranged in battery side by side and extending in two rows with opposite fireplaces back to back, fireplaces being provided with crown arch composed of arched slabs, key slabs having tapered sides, and key block having tapered sides and opening for escape of gas, main gas flues extending above fireplaces of each row and receiving gas from key blocks of several arches, niter oven to which main gas flues discharge at one end, fines-burning flue extending longitudinally above one of main gas flues, means for supplying fines to burning flue, and return or dust flue connecting at one end with forward end of fines-burning flue and extending thence rearwardly alongside fines-burning flue and discharging at rear end to one of main gas flues.

APPARATUS FOR TREATING CRUSHED ORES, SLIMES AND OTHER MATERIALS.—No. 798,568; A. Z. Clark, Melbourne, Victoria, Australia.



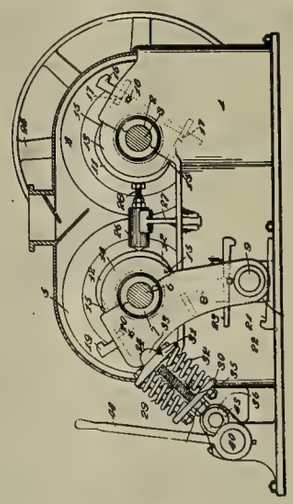
Combination of flat-topped block formed with series of openings of different sizes, and with recesses in top face adjacent to openings, pawl in each recess formed with flat top and of size to lie flat in recess with top flush with top of block, one end of each pawl beveled and toothed and projected into adjacent opening and pins passed through blocks and pivotally supporting pawls in recesses.

ORE CONCENTRATOR.—No. 798,064; W. O. Journeay, San Antonio, Tex.



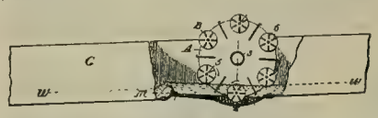
Improved ore concentrator comprising main pulp receiver and concentric chamber pendent therefrom, pulp hopper having vertical body arranged concentrically within receiver, concentric rotary shaft to which hopper is attached, agitator attached to hopper and rotating together with it and shaft, overflow hopper surrounding upper portion of main receiver which is provided with openings at that point, tailings spout connected with overflow hopper, vertically reciprocating plunger arranged in hopper and means for reciprocating same to cause pulsations in mass of pulp, water jackets applied to main receiver and concentrate chamber and communicating with same by openings, cut-off valve arranged between main receiver and concentrate chamber, and discharge valve applied to latter.

CRUSHING ROLLS.—No. 798,415; R. K. Humperey, Denver, Colo.



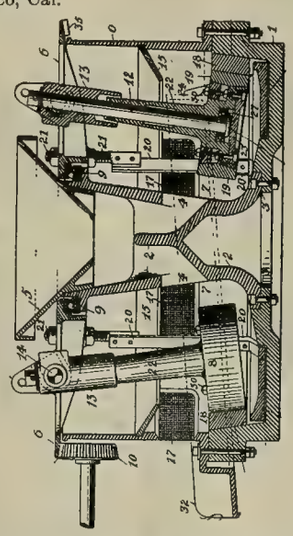
Crushing roll mechanism comprising crushing rolls, pillow blocks mounted movably in proper relation to rolls and provided with bearings for shafts of rolls, cap plates for covering bearings, pillow blocks having apertures extending through them upon each side of bearings, straps inclosing caps, and extending at ends through apertures, and inclined tapering keys engaging ends of straps for preventing withdrawal from apertures.

AMALGAMATOR. — No. 797,740; E. S. Moss, Chicago, Ill.



Amalgamator comprising sluice having depression for mercury, movable supporting frame mounted over depression, series of wheels revolubly mounted in frame, each of wheels being provided with series of longitudinal amalgamated blades, adjustment of frame being such as to cause one or more of blades to be immersed in mercury when frame is actuated, and riffle adjusted to raise level of passing slimes to top of lowermost wheel, whereby blades of each wheel may be freshly amalgamated and rotated within slimes while permitting unobstructed passage of latter.

CENTRIFUGAL WET CRUSHING AND GRINDING MILL FOR QUARTZ.—No. 798,278; L. C. Graupner, San Francisco, Cal.



In centrifugal ore crushing machine, pan constituting base, die-ring with inclined face secured to inner wall face of pan, central conduit secured to pan, having lateral openings for delivery of ore to rollers, disk plate revolubly mounted on top of conduit on suitable bearings, and plurality of pendulously mounted rollers carried by plate, their faces arranged to contact with and press laterally against die-ring.

MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

Consul Williams of Cardiff, Wales, furnishes the following output of tin by countries for the last three years as approximately correct:

Countries.	1902. Tons.	1903. Tons.	1904. Tons.
Malay States	53,756	54,797	58,657
Banca and Billiton	18,765	20,000	14,638
Bolivia	10,150	9,500	9,200
England	3,950	4,150	4,282
Australia	3,206	4,991	5,082
Miscellaneous	350	395	384
Totals	90,177	93,883	92,243

According to these figures the production of tin is almost at a standstill, and there was an actual falling off in the output during 1904. On the other hand the consumption is on the increase, and the accepted estimate for 1904 is as follows:

Countries.	Tons.
United States	38,000
Great Britain	15,898
Germany	14,832
All other countries	25,525
Total	94,755

Thus the consumption for the year was 2512 tons in excess of the output. Ordinarily the tin consumed is lost forever, but the increasing demand and the threatened diminution of the available stock has given rise to a new industry, the detinning of tin scrap. The statistics show that the United States consumes over 40% of all the tin produced.

Director of the Mint Roberts' estimate of the production of gold and silver in the United States for 1904 shows an increased production over the calendar year 1903 of $7,131,500 gold and 3,486,000 fine ounces of silver. The largest gold gain was by California, which increased $3,000,000 more than in the previous year, and a larger amount than in any year since the 60's. This gain came chiefly from dredger operations, and a further gain is expected during the current year and for some years to come. Colorado shows an increase of nearly $2,000,000 gold and 1,300,000 ounces of silver; Alaska a gain of $700,000 gold; Montana a gain of 2,000,000 ounces of silver; Utah a gain of 1,300,000 ounces of silver; Idaho a gain of 1,300,000 ounces of silver. Forty-eight per cent of the silver was produced from lead ores, 26% from copper ores and the rest largely from ores which also carried gold.

States.	Gold. Value.	Silver. Fine Ozs.
Alaska	$9,034,200	210,800
Arizona	3,343,900	2,744,100
California	19,109,600	1,532,500
Colorado	24,395,800	14,331,600
Idaho	1,503,700	7,810,200
Montana	5,097,800	14,608,100
Nevada	4,037,,800	2,695,100
New Mexico	381,900	314,600
Oregon	1,309,900	143,200
South Dakota	7,024,600	187,000
Texas	2,300	469,600
Utah	4 215,000	12,484,200
Washington	327,000	149,900
Wyoming	16,400	4,400

The total gold production was $80,723,200; silver, 75,786,100 fine ounces. The total amount of gold mined was 3,904,986 ounces and the commercial value of the silver produced was $33,515,938, making the total value of the two metals $114,239,138.

ALASKA.

A gold strike made last November on the upper fork of the Yentna river, 120 miles from Cook Inlet, has become known. Sixty miners from the Cook Inlet camp have stampeded to the Yentna and will winter there. It is said that eleven men working this summer on Kahilta have taken out $10 a day each.

ARIZONA.

Cochise County.

A company has been organized to prospect for coal near Morenci.

Connection of Nos. 2 and 3 furnaces of the Calumet & Arizona Co.'s smelter at Douglas has been completed and No. 1 furnace will be completed as speedily as possible. The new power crane is in position and has been tested without load with highly satisfactory results. It will be three weeks before the building in which the crane is located is ready to permit of operations of the machinery.

Graham County.

A company has taken hold of the oil fields about Safford and has commenced boring operations. P. Anderson has charge.

Mohave County.

Ore has been opened up in the shaft of the Hot Tom mine at Chloride belonging to T. B. Scott. A gasoline hoisting engine will be put in to facilitate hoisting. —— The Connor-Minnesota mine at Chloride has struck a 5-foot vein of high-grade silver ore. ——E. Clark of Spokane, Wash., has taken a bond and lease on the Yellow Ned mines in El Dorado district.

Water in the Cyrus Noble mine, in Searchlight district, is causing trouble. It has come into the 400-foot level of the mine and all work has been transferred to the first and second levels. —— J. V. Clark of Ocean Grove, Cal., and H. V. DeHaas of Los Angeles, Cal., have purchased an interest in the Little El Dorado M. Co., in Crescent district. A 200-foot shaft is to be sunk on the property at once and drifts run for 500 feet north and south in the hope of catching parallel veins of ore. ——The Old American Flag mine on Big Wallapai mountain, 15 miles east of Kingman, has been cleared of debris and water in the lower workings preparatory to a resumption of work.——H. J. Heffron of Los Angeles, Cal., has started work at the Alpha mine, at Layne Springs.

Pima County.

L. M. Robinson, manager of the Robinson-Arizona Co., operating in the placer section at Greaterville, says that the company is waiting for water, and for the Interior Department to confer the privilege of allowing the company to build a reservoir of 3,500,000 gallons capacity.

Pinal County.

The experiment being tried by the Ray C. Co. at Kelvin is satisfactory and promises success, which may turn the concentrating plant into a 500-ton leaching plant.——The Big Lead M. Co. in the Kelvin district is said to be getting 3½% copper ore. A small leaching plant is to be built.

Yavapai County.

Superintendent S. Sessions of the Gold Lode M. Co. has finished grading for a 10-stamp mill. They will put in a cyanide plant.—— The hoist has been started at the Pickaway mine, east of Val Verde.

The Bunker Hill G. M. Co. is pushing its deep working tunnel, 8 miles from Val Verde. The company stopped work on its main shaft and decided to open and operate its property entirely through the deep working tunnel. The distance between the mouth of the tunnel and the main shaft is 1800 feet.

It is reported that the Tiger G. M. Co. intend| sinking a double-compartment inclined shaft on the Gray Eagle vein at Harrington. It is planned to connect this with a winze from the Cleveland tunnel. They also intend putting in a 20-stamp mill in addition to the 20-stamp mill now running. G. P. Harrington is manager and T. S. Schlesinger manager.——The Apache Panther G. M. Co. is running a development tunnel to open up their claims near Harrington. It is planned to run this 1300 feet. J. C. Ray and Bernard Cunniff are interested. —— The Saratoga G. M. Co. is running a drift to connect their 155-foot vertical shaft with an abandoned shaft on the Silver King. O. F. Place is president and Ed Foltz foreman.——Superintendent S. R. Trengove is sinking a shaft on the Colonel M. Co.s land, near Crown King. It is to be sunk 500 feet and is down 180 feet.

The following is reported as the details of the Pohle-Croasdale process to be used by the Rigby Mining & Reduction Co. at Mayer: From the bins the ore is taken by car to the dryer, where it passes through two revolving dryers—one of 40 inches diameter by 18 feet long, the other 60 inches diameter by 26 feet long—the hot ore passing from them by gravity to cars, which take it to the feed hoppers in the rollhouse, having three sets of 30x14-inch rolls and a set of 20x12-inch rolls with the necessary screens, elevators, etc. The dust due to crushing is collected by three large automatic fans and dust collectors. The crushed ore is taken from the screens to a 40-ton iron ore bin in the mixer house by an automatic belt conveyor 84 feet long. Here the ore and the salt from a smaller bin are weighed by two sets of hopper scales and deposited on a 60-foot belt conveyor, which takes it to a box mixer, whence it is dumped into a car, which takes it to the four feed hoppers, from where it is automatically fed into four revolving furnaces, and the ore, after passing through them, is dumped into an ore conveyor that carries it to cars which place it in the tailings dump, its values having been volatilized and taken to another department. The furnace room is 88 feet wide, 133 feet long and 40 feet high. The fumes are drawn from the furnaces through the flue house, which contains four sets of 3-foot wrought iron pipe 175 feet long, into the condensing house by four large pressure blowers, each capable of handling 6600 cubic gas of feet per minute, and on reaching them is forced into the condensing chambers, where the gold, silver, copper and lead are recovered. From the solution thus obtained, the gold, silver and lead values are filtered and the copper is precipitated either by electricity or iron and the precipitates melted. It is reported that the extraction of metal values is accomplished in the furnace by the application of heat to the mixture of ore, salt and sulphur, causing the sodium of the salt and the sulphur to unite as sulphate of soda and freezing the chlorine of the salt, which unites with the metals, forming gases, which are drawn from the furnaces and forced into the condensers by the pressure blowers.

CALIFORNIA.

Production of quicksilver by flasks in California, by counties, during 1904 was:

County.	Quantity.	Value
Colusa	400	$17,400
Lake	3,044	132,414
Napa	5,329	231,811
San Benito	8,480	368,880
San Luis Obispo	4,896	212,976
Santa Clara	3,889	169,172
Solano	377	16,400
Sonoma	2,700	117,450
Trinity	102	4 437
Total	29,217	$1,270,940

In California it is estimated that the dredger mining field covers 25,050 acres. The Feather River district has 7500 acres, Yuba River 5000, Bear River 1000 and American River 5000, the balance being scattered in Shasta, Plumas, Siskiyou, Calaveras, Trinity and Stanislaus. The value of the ground in the larger fields runs from 17 cents to 30 cents per cubic yard.

Butte County.

Robert D. Evans and other stockholders of Boston have sold their holdings in the Boston & Oroville, Boston & California and Bear River companies to the Venture Corporation, Limited, of London. The latter concern has incorporated under Maine laws the Oroville Dredging Co., Limited, with a capital of $3,500,000 in $5 shares to take over these. The Venture Company transferred the stock it purchased, which included all the Boston & California and Bear River companies and a majority of the Boston & Oroville stock to the American concern as an operating company. A number of other dredging companies are to be included. F. W. Baker is the president and F. W. Batchelder the treasurer.

Calaveras County.

E. J. West has bonded from W. T. Robinson the Look Out quartz mine, near the Calaveras river, in the San Andreas district. An option has also been secured on the Hexter mine, west of Mokelumne Hill, and operations will be resumed.

El Dorado County.

The Pacific House drift has been sold by J. E. Sexton to a company headed by L. E. King of Cripple Creek, Colo., and I. H. Bingham of Eugene, Or. Drilling is to be done before running the tunnel.——At the Crusader mine, El Dorado district, Seymour & Frick are pushing development work.——At the Alcimentes mine, Smith's Flat district, they have developed a fine body of gravel.

Mono County.

The Liberty-Pittsburg claims in the Masonic Mountain district, near Bodie, have been taken over by the Tonopah M. Co.

Nevada County.

High-grade ore has been struck by leasers in the 200-foot level of the Union Hill mine, near Grass Valley.

A rich strike is reported at the Kenosha mine at Deadman's Flat, near Grass Valley.——A shaft is to be sunk on the Iron Mountain copper prospects, near Spencerville, by E. A. Wiltsee. Borings have been made.

San Luis Obispo County.

The Western Mining & Steel Cor. will commence diamond drill prospecting for copper and iron on ranches on Los Osos, near San Luis Obispo.

Shasta County.

The miners and smelter men at Ingot have organized a union, a branch of the Western Federation of Miners. Organization was effected through J. C. Williams of Grass Valley, vice-president of the Federation. The union starts out with a charter membership of thirty. Homer Dehaven was elected president and Albert Lane secretary.——At the new Mammoth smelter at Kennett the ore crushers connected with the sampling rooms have been crushing the H. H. Thompson's ore from Old Diggings.

Fire at Redding destroyed the Central cable station, together with several ore cars and a train of the Ried mine, under bond to Hunt & Sallee. Ore bins just ready to be filled with an ore shipment to the Kennett smelter were destroyed.

The ore body in the Midas mine at Harrison Gulch has been found in the 900-foot level.

Sierra County.

The Forest City M. Co. is drifting on the channel of the Mabel Mertz, recently reached on the western rim after running 1600 feet. H. B. McCormick is superintendent. The mine is at the junction of the Mabel Mertz and Balsam Flat ridges, 5 miles east of Forest.——A. J. McCoy has charge of driving the tunnel on the Mabel mine, adjoining the Mabel Mertz.——The Alleghany M. Co. is driving a long tunnel in the Balsam Flat ridge. ——At Minnesota, south of Alleghany, the channel is sought by F. B. DeLauney of Chips Flat.——At the last Resort mine, near Downieville, a new crosscut tunnel to catch the vein is being run by Manager A. L. Wilson. The company proposes to put in a 3-stamp mill.

Tuolumne County.

(Special Correspondence).—A number of mines have been temporarily closed on account of a shortage of water. The Black Oak mine, mill and cyanide plant at Soulsbyville have been shut down. Pumping is being continued with steam power.——At the Rawhide mine near Sonora the plates are being replated with silver during the shut-down.——The mine and mill at the App have been closed.——The Shawmut is shut down, but the chlorination plant is running.

Soulsbyville, Sept. 13.

The Wheal-Perrin mine, near Soulsbyville, is being unwatered.——The Sunnyside mine, south of Toulumne, on the Tuolumne river, has been bonded to W. P. Cunningham, who is putting in an air compressor.

Work has been stopped at the Ranch gravel mine, near Columbia, pending the action of New York directors.——The Santa Ysabel mill at Stent is to make a test run on ore from the mine as soon as water power is available.——The new 5-stamp mill on the Fair Oaks mine, near Confidence, has started up. The main tunnel is in 150 feet on the vein. At the mouth of the tunnel a 2-compartment shaft has been started and is down 40 feet. When 150 feet is reached drifting will begin.—— James Hamilton, superintendent of the Don Pedro gold mines, 21 miles from Jamestown and 9 miles from Cooperstown, is putting in a 30 H. P. new air compressor. The main shaft is 200 feet deep. Workmen are grading for a 10-stamp mill.——The company operating the Surprise gravel mine at Dead Man's Bar, west of Sonora, and secured under bond from its owner, Otto Kanig, is making good progress on the property, with John Heath as superintendent. Bed rock has been struck after sinking 35 feet. The work of crosscutting the old river channel is under way.——At the Republic, in the Parrott's Ferry district, the main tunnel is in on the vein 800 feet and being driven ahead. The mill is hung up owing to a scarcity of water.——The underground forces in both the Grizzly and New Albany have been increased. The tramway connecting the properties is nearly completed.——A new incline is being sunk alongside the old 160-foot one on the Manzanita. When a depth of 90 feet is reached the vein will be stoped out to within 40 feet of the surface.

Yuba County.

Frank Weston of San Francisco has bonded from James O'Brien, J. E. Ebert and T. A. McKenna 1200 acres of dredger mining land 4 miles east of Marysville at $375 an acre. Sacramento capitalists have bonded 1000 acres adjoining the town for $200 an acre.

COLORADO.

(Special Correspondence).—Since the merger of the various railroads entering the Cripple Creek district the operators have received notice of an advance in freight rates. The Short Line, which was built by the operators a few years ago, was built to compete with the roads already entering the district and to relieve the high rates then in vogue; but, on account of some of the stockholders of the Short Line having disposed of their

holdings, the operators have lost control of the road—hence the advance in rates. It is now reported that a smelter will be built to handle the ores from the district and in competition with the mills and smelters now handling the ore.

Work has been commenced in Gore canyon by the Moffat road. This canyon was claimed by the Reclamation Service of the United States, and an injunction was brought against the road to prevent it from using same. Judge Hallett rendered a decision a few days ago in favor of the road. This will give the road an outlet into Routt county, and be the means of opening up valuable coal and mineral lands.

Denver, Colo., Sept. 11.

Arapahoe County.

The American Zinc & Chemical Co.'s plant at Utah Junction, north of Denver, was totally destroyed by fire Sept. 8. The plant was a combination smelter and chemical works. C. F. Dewey is the manager.

Boulder County.

Wm. Scott of Nederland has put machinery on his tungsten property.——J. H. Kemp intends to remodel the Eldora chlorination mill to a cyanide plant, preparing it to treat ores in Eldora and surrounding camps.

Chaffee County.

The Colorado Commonwealth M. Co. is operating near Marysville, near Salida. W. A. Redenberg is president; J. Kestler of Marysville, vice-president; C. J. Brock, secretary and treasurer. —— The Fourth of July M. Co. has claims near Turret. J. A. Seemann of Turret is president.

Clear Creek County

Work has been resumed on the Poorman property above Freeland by J. and R. W. McKenzie. The workings below the tunnel level are filled with water. At a distance of 250 feet from the portal of the tunnel an upraise of 60 feet will be made to connect with the bottom of a 40-foot shaft on the Poorman vein, and with an 80-foot winze. At the bottom of the latter a crosscut has been run to the No Name vein. —— On Columbus mountain, near Empire, work is being done by the Krupps M. Co. under the direction of F. M. Tucker.

The Loop Mines & Tunnel Co. has been formed to develop claims on Republican mountain, near Silver Plume, by means of a tunnel to be driven at least 2000 feet. —— Preparations are being made to resume operations on the Josephine property, which lies near the A.–P. tunnel on Kelso mountain, near Silver Plume. I. B. Nichols has been getting things in shape for putting men to work.

Gilpin County.

During the last week of August the shipments of smelting and crude ores, tailings and concentrates from the Black Hawk depot to the Denver smelters and outside points of treatment were 58 cars, or 1220 tons, making a total of 281 cars, or 5900 tons, for the month. In comparison with the preceding month, last month's shipments showed a gain of 55 cars, or 1135 tons, an increase of nearly 25% over the shipments for July, while for the corresponding month of last year the shipments showed a gain of nearly 20%.——Because of a cave-in of the shaft at the 200-foot level, work has been suspended by the Newfoundland Gold & Silver M. Co., near Central City. G. W. Mabee, Jr., is superintendent. It is reported that a new shaft will be sunk.——The new mill of the Monarch Mill Co., in Gambell gulch, near Central City, is running double shifts, principally on ores from the Colorado tunnel, but it is to be run also on ores from the Mountain Monarch property. The new mill is equipped with five rapid drop stamps, copper plates, bumping tables and a concentrating table. It is the intention of the company to put in five more stamps and additional tables. J. C. Barrows, of Rollinsville, is manager and G. C. Carson millman.——Work has been resumed on the O. K. mine on German mountain, near Central City, by A. Johnson. Retimbering of the shaft and other repairs will have to be made before work underground can be pushed. The shaft is down 600 feet.——A 30 H. P. hoist has been put on the Gladstone mine in Lake district.——Central City reports say that the Golden Sun M. & M. Co. will put in an air compressor at their claims east of Boulder park on the south side of South Boulder creek. The main tunnel, being driven by Peterson & Co. under contract, is in over 300 feet. L. A. Shearer is superintendent.——The Denver & Northwestern M. Co., on South Boulder creek, intend putting in a compressor.

The Mountz & Palmer mill, near Apex, is running on ores from the Mackey mine and the Sarah Jane tunnel. Air drills are opening new ground in the Mackey.—— The Boston Occidental Co., operating the Mascot mine at American City, sunk its shaft an additional lift and is now crosscutting for its vein at the lowest level. The company has its drying room at the millr eady for use and will soon be ready to treat its own ores at the minedump. —— W. Shultz of the Shultz Wonder is prospecting for ore shoots in his underground workings.——The Imperial M. & M. Co. and the Cyrene Mines Co. have consolidated, the Imerial taking over the property of the Cyrene Co.——Surveyors from Yankee have run a line for a wagon road from Yankee to Tolland on the Moffat Railway. The road will be run on a 10% grade. The Moffat management promised to build the first mile from Tolland.——The Palace M. Co. is underhand stoping on a shoot of lead ore in their tunnel.——The Little Sallie M. Co. has bought the Marie Louise group of claims on Silver creek and intends putting up a mill to treat their ores near the mine dump. W. E. Garver is the superintendent.

Gunnison County.

The Carter tunnel of the Ashland M. Co. is said to have cut good veins at the 1450 and 1490-foot points. It will be continued until in 3500 feet, when it is estimated that all the important veins will have been cut. New air compressors will be put in. C. W. Carter is manager.

In the Tin Cup district the Blistered Horn tunnel has been driven 1600 feet and struck a 7-foot vein of ore at a depth of 1000 feet. —— I. L. Johnson is running a long tunnel from Middle Willow creek to get under the old workings of the Gold Cup.

Hinsdale County.

High-grade ore is being shipped from the St. Jacob's mine at Carson, 14 miles south of Lake City. It is reported that a new shaft is to be sunk.

Lake County.

A tunnel is being run from the level of the Adams mill, Carbonate hill, Leadville, into the mill to tap the Wolftone shaft at a point 100 feet below the present mark from which water is being lifted. The tunnel will be 480 feet in length, and when the shaft is tapped will do away with some pumping, and the ore from the mine will be dumped into the bins at the mill. The tunnel will be 5½x6½ in the clear. —— The lessees on the Fortune, Big Evans, Becker & O'Brien have completed all of the surface work and are hoisting fifty tons a day of siliceous and sulphide ores from the upper and one of the lower levels. Where the work is being carried on the drifts will be driven farther ahead and to the north. The levels at the bottom of the shaft will be worked later, when arrangements will be made to handle the water.

Work has been resumed at the Bartlett mine, near Twin Lakes, by the Twin Lakes G. M. Co.—— Geo. Miller has charge of work on the Sunnyside mine, near Twin Lakes. —— The Last Chance Co. have resumed work on their Echo canyon claims. S. E. Smith of Twin Lakes has charge. —— The Bromley mill is being moved to Lackawanna gulch.

San Juan County.

At the Sound Democrat claims in Mastodon gulch, near Silverton, Walker & Ezell are finishing the structural work of a new 10-stamp mill.

San Miguel County.

Prior to the leasing of the greater portion of the Smuggler-Union mine and both the Smuggler-Union mills to Robeson & Carter the mills were under different managements. It is understood the new leasers will put both plants in charge of M. R. Hansen. W. J. Thomas, who has been foreman of the Suffolk-Globe 40-stamp mill at Ophir, will be head amalgamator.

Summit County.

On the Star placer, in the Upper Blue valley, Superintendent Dearing is prospecting and extending ditches, pipe lines and flumes.——M. Anderson and J. Cramer, leasing the Washington property, on Nigger hill, near Breckenridge, reached through the Wineland and Mayo tunnels, are shipping lead-gold ore.——The American Dredging Co., while prospecting its placer territory on the Swan, has sunk thirty-nine drill holes to bedrock. The holes vary from 38 to 40 feet in depth. Careful pannings and assays have been made and records of each hole kept, and when dredging is resumed the company will be in possession of data concerning gold values and depth of wash on each tract.——Excavation has been completed for an addition to the mill of the Washington–Joliet Co., on Nigger hill. Development is being pushed in the Puzzle–Extension shaft, and a drift now being driven from the 100-foot level will cut the ore shoot at greater depth.——The Hoosier Creek G. M. Co., operating the Bemrose placers, Hoosier gulch, near Breckenridge, has been sinking a shaft to cut an iron ore vein on the dip. At 110 feet from the surface a station was put in and a crosscut drift was driven from the vein.——At the Old Union mine, near Breckenridge, the main tunnel is near the 1000-foot mark. A crosscut will be driven west to the Old Union main ledge, a distance of 150 feet, and a crosscut east will cut two other veins. A continuation of the tunnel for 500 feet will put the breast of it under the main shaft workings, when connections will be made. The company is taking out milling ore.——At the Novelty mine, being worked by J. Detwiler and the Summit County Mining Exchange, the whim has been put into position and the main shaft baled out. The shaft will be sunk 50 feet on contract, and then will begin the work of taking out ore for shipment.

Teller County.

An 8-drill belt compressor driven by electric motor has been put in at the Los Angeles mine by the Exposition Mines & Leasing Co., and work has been renewed on low-grade ore bodies of the Los Angeles to supply the cyanide mill. A skip will be put in the shaft and hoisting resumed.——Superintendent J. McIlwee has opened up good ore in the Maid of Orleans shaft on Beacon hill, Cripple Creek. The shaft is to be sunk from the 500 to the 600-foot level.——Work has been resumed at the Elkton after a short shut-down during which repairs were made in the main workings.——The Long John shaft on Ironclad hill, Cripple Creek, which is to be sunk to a depth of 200 feet, is down 145 feet. A. W. Oliver is interested.——The Hull City mine of the Independence Con. G. M. Co. is shipping 1000 tons monthly. W. P. Dunham of Colorado Springs is manager.——Lessee Walsh has started a crosscut from the 610 level of the Forest Queen shaft on Ironclad hill, Cripple Creek. ——The Dexter G. M. Co. recently granted a lease to O. M. Deemer and J. F. O'Neill of Omaha on the Dexter and other of its claims on Bull hill, near Cripple Creek. The lessees have put in a temporary small hoist, pending the arrival of an 80 H. P. boiler, a 10x12 hoist and a 5-drill air compressor. The shaft is down 625 feet.

IDAHO.

Blaine County.

The Wood River Zinc Co.'s mill near Hailey is temporarily shut down because of breaking of the main line shaft. New crushing machinery and more concentrators are being put in.——The development work at both the Nay Aug and War Dance mines is being continued. At the Nay Aug a raise to the surface is being started for air.

The Lipman Tunnel & Mines Co. intend starting work on their 3000-foot tunnel from the south side of Bullion camp, near Hailey, in the Wood River mining district. The tunnel will give an outlet to the Red Elephant, Bullion and Mayflower mines, and save the expense of hoisting and pumping. An incline shaft is to be sunk on the Point Lookout to connect the lower tunnel with the upper workings.

Boise County.

The Black Pearl M. Co. at Pearl is putting in a cyanide plant.

Manager W. T. Nasseur of the Whitman Co.'s property at Pearl states that the adit level on the Leviathan vein has been driven 622 feet. The adit level on the Red Warrior vein has been driven 521 feet.

Shoshone County.

At the Success mill, near Wallace, twelve jigs are to be put in to increase the present capacity of 200 tons. Settling tanks are being built to handle the zinc tailings, and new concentrating tables will be put in to work over the settlings from these tanks. The average assay value of the feed since the mill went into operation, three weeks ago, has been 20 ounces of silver, 25% lead and 25% zinc. Two kinds of concentrates are obtained. The lead contrates run from 40 ounces to 45 ounces of silver and from 50% to 65% in lead, with practically no zinc. The zinc concentrates contain almost no silver values, 3% lead and run from 45% to 50% zinc. The separation of the zinc and lead is made with the tables, no electric magnets being used.——The Dominion M. Co., of which C. E. Poor of Los Angeles, Cal., is manager, has let a contract to W. W. Shaw to run 300 feet of crosscut tunnel to reach its main ledge near Wallace, making the tunnel, when the present contract is complete, 665 feet in length.——The Rochester claims, 12 miles southwest of Wallace, have been incorporated and preparation will at once be made to develop them. The property is now owned by the Mastodon-Cœur d'Alene M. Co. J. F. Firch of Spokane is president; A. M. Mundell of Wallace, vice-president; C. P. Ward of Spokane, secretary.

Foreman John Thyne of the Golden Chest mine, near Murray, reports that the Idaho tunnel for the month of August was advanced 220 feet. The tunnel is 6½x9 feet. The work was done by nine men in two shifts. Power drills were used. The cost per foot was $6. Miners and shovelers received $3.50 per shift. The tunnel must be driven 400 feet farther to get under the Klondike shaft. ——Work has been started on the 20-stamp mill of the Golden Reward mine, near Murray. C. S. Crysler is manager.

The appraisers appointed by Judge Beatty to determine the loss suffered by Headrick & Baillie by having their claims, the Blackhawk and Alvy, traversed by the great Morning tunnel of Larson & Greenough, found that the claims had suffered no damage by being traversed by the tunnel, but were benefited. As compensation for the ground used by the tunnel, Headrick & Baillie were awarded $97.16. This is the first case of the kind ever brought in the courts of Idaho. Larson & Greenough instituted condemnation proceedings against Headrick & Baillie for right of way for Morning tunnel No. 6 through the Blackhawk and Alvy claims. They claimed that the only complete, successful and profitable manner of working the Morning mine is by this tunnel, which has already been driven 1½ mile, and that to reach the ore bodies through this tunnel, it is necessary to drive it for some distance through the Blackhawk and the Alvy claims. Judge Beatty decided in favor of Larson & Greenough and appointed F. F. Johnson and E. H. Moffitt of Wallace and Al Page of Wardner as appraisers to determine the amount of damage done.

The directors of the Tamarack & Chesapeake M. Co., owning a property near Wallace, have decided to commence shipping ore from the mine. An arrangement for the treatment of the product has been concluded with the Salt Lake smelter. The ledge has been drifted upon in ore for 250 feet, at a depth of 500 feet.

MICHIGAN.

Houghton County.

(Special Correspondence).—The Wolverine ore returns a trifle better than thirty pounds of copper to the ton. The Calumet & Hecla has an average of forty-five pounds of metal per ton and the branch vein of the Michigan averages thirty-two pounds of copper per ton. The Allouez, Ahmeek, Wolverine, Mohawk, Centennial, North Kearsarge and South Kearsarge mines are producing copper regularly from rock mined out of the Kearsarge amygdaloid bed. The Calumet & Hecla is opening a good mine upon the same lode, while the Miskwabik has a promising prospect upon its northern extension and the Tecumseh has a chance of making a mine to the southward. The Baltic lode has three mines developed —the Baltic, Trimountain and Champion. A fourth mine is being opened to the northward by the Superior Copper Co., while a fifth is to be opened later on Section 16 by the Atlantic Co. A sixth is being started on the Globe tract, south of the Champion, while a seventh is being developed at the Challenge property of the St. Mary's Mineral Land Co.

Houghton, Sept. 11.

MISSOURI.

Jasper County.

The shaft of the Union Zinc Co., on the Lyon M. & D. Co.'s lease between Prosperity and Duneweg, has reached ore.——A new mill is being constructed on the Longen land, north of Chitwood, by Chitwood and associates. ——A 200 ton electric mill is being built by the Maud L. M. Co., on the Leonard land, north of Chitwood.

MONTANA.

The report of B. H. Tatem, assayer in charge of the United States assay office at Helena, for August, shows that the total receipts of gold from Montana during the month were $192,289.96. The contributions of the counties follow: Fergus, $71,142.37; Lewis and Clark, $21,-745.97; Missoula, $13,039.64; Chouteau, $14,682.63 from other places; British Columbia, $22,725.87; Alaska, $4109; Nevada $7928.95. Total receipts from all sources, $209,979.18.

Missoula County.

Copper ore is being shipped to the Tacoma smelter from the 300-foot level of the Monitor mine at Saltese. President Otis Hill is at the mine.

Silver Bow County.

(Special Correspondence).—In August the Butte dis-

trict yielded 449,500 tons of copper ore, from which were produced 28,356,940 pounds of copper:

Companies.	Monthly Tonnage.	Pounds Per Ton.	Monthly Production.	Daily Production.
Anaconda	142,000	54	7,700,400	248,400
Boston & Montana	80,800	70	6,076,000	196,000
Butte & Boston	18,000	65	1,209,000	39,000
Parrot	17,300	70	1,215,200	39,200
Washoe	26,350	70	1,844,500	59,500
Trenton	16,710	66	1,101,810	35,610
North Butte	26,350	80	2,108,000	68,000
Corra Rock Island	18,000	60	1,116,000	36,000
Rarus	21,700	60	961,000	12,000
Minnie Healey	15,500	62	1,302,000	31,000
Belmont	3,100	55	170,500	5,500
Clark's mines	40,300	65	2,619,500	81,500
Miscellaneous	15,500	60	930,000	30,000
Totals	448,900		28,356,940	914,710

The Washoe smelter of the Amalgamated Company, which treats the ores of the Anaconda, Washoe, Parrot, Trenton, Butte & Boston and North Butte companies, produced 15,181,940 pounds, and the Boston & Montana smelter at Great Falls 6,076,000, making the total Amalgamated output 21,257,940 pounds of copper. The total for the United Copper Co., including the Rarus, Minnie Healey, Corra and Belmont, was 3,549,500 pounds.

Butte, Sept. 11.

It is reported that there has been a rich strike of gold in one of the United Copper mines, near Butte. The mine is in the Lexington group. A large body of ore was uncovered on the 200-foot level. It is said to run 104 ounces in gold and 124 ounces in silver to the ton.

The Little Annie Mine No. 2, northwest of Walkerville, has been sold to the Cobban Realty Co. of Butte. The mine was owned by Clinto Ramsdell of Deer Lodge.

At the Reins Copper Co.'s mine at Butte, the shaft is near the 900-foot level. The work will be continued until the 1200 mark is reached. Then a station large enough to accommodate a pump will be cut and a crosscut started. No ore is being mined, and it is the intention of the company to not attempt to extract any until the development work under way is finished. While sinking is in progress, another crew is raising from the 800-foot station to the surface, in order to make the shaft uniform in size its entire depth. The large pumps on the 800 station are working well, and there is therefore no trouble in keeping the water out of the shaft.

NEVADA.

Esmeralda County.

The railroad between Tonopah and Goldfield has been completed and trains are now running. Goldfield is 28 miles south of Tonopah; 16 miles south of Goldfield is Tank Springs; 29 miles south is Summerville, the new strike, which is 3 miles west of Thorp's Mills; 27 miles south from Summerville is Muddy Spring; 8 miles south from Muddy is Old Bullfrog or Amagoza (now deserted); ¾ mile south is the new town of Bullfrog, formerly called Bonanza. From Ryolite to Beatty, a town of 500 people, is 4 miles northeast, passing the Montgomery Edwards mine. South from Beatty, 4 miles, is Gold Center, with 250 people; 110 miles southeast from Bullfrog are the rich strikes of Las Vegas.

Lincoln County.

It is reported that the Searchlight Parallel G. M. Co. has bought a 15 H. P. hoist for its mine at Searchlight. The main shaft is 200 feet deep.——G. F. Colton announces that the development of the New Year's Gift Fraction at Searchlight will be continued.——The Good Hope property will be developed to deeper levels.——The Searchlight shaft will be put down deeper. The company has decided to develop the Gypsy claim.——Water has been struck in the main shaft of the Sazerac mine at Searchlight at a pepth of 215 feet. Sinking has been discontinued until pumps can be put in.——The Searchlight M. & M. Co. have started the new 3-stamp mill. Sinking is to be resumed when the pump is repaired.——B. Macready states that the main shaft of the Santa Fe mine at Searchlight will be sunk to the 500-foot level.——The mine will be equipped with a 25 H. P. gasoline hoist, a Cornish pump, ventilating appliances, and cut-off and rip saws for preparing mine timbers. The Santa Fe M. & M. Co.'s property includes the Barney Riley, Santa Fe, Telluride, Pan American, Georgetown and Erie. The main shaft is 170 feet deep. Water was struck at 165 feet, and prevented further sinking.——The pump and hoist has been put in at the Pompeii at Searchlight, and pumping is to be started preliminary to sinking to the 600-foot level.——D. C. Spence, representing an Eastern oil company which recently leased 5000 acres of land in Muddy valley, near Logan, for drilling for oil, will begin operations soon.

Nye County.

In the double-hand drilling contest at Tonopah, September 4th, Wm. B. Ross and Walter Bradshaw of Tonopah drilled 43 7/16 inches in fifteen minutes; J. McIver and C. Make of Bisbee, Ariz., drilled 43¼ inches, and McElvary and Bijorn of Goldfield drilled 38 7/16 inches. Fred Youckey of Tonopah drilled 28⅝ inches in the single-hand contest, and Walter Bradshaw drilled 25 1/16 inches.

NEW MEXICO.

Dona Ana County.

The Stephenson-Bennett Con. M. Co. at Las Cruces has put in a new air compressor and is pushing work on its double-compartment shaft, which will be sunk to a depth of 450 feet. —— The Modoc M. Co. is to try another dry concentrating process at its property in the Organ mountains, near Las Cruces. Changes are being made in the old plant. Shipments of lead ore are being made to the smelter at Deming.

Grant County.

The Hermosa Copper Co. at Hanover will sink 1000 feet on the Ivanhoe as soon as three hoists, aggregating 300 H. P., and the necessary boilers have arrived.

Lincoln County.

The Eagle M. & I. Co. will soon have a new mill to treat its low-grade gold ore. This will give a capacity of 150 tons of ore daily. The company's property is between Carrizozo and Capitan.

Otero County.

The Lincoln Copper Co., having made arrangements with the Southwest Smelting Co., which is to build blast furnaces at Jarilla to handle its ore, announces that it will resume sinking its double-compartment working shaft on its property.——The Southwestern S. & R. Co. has let a contract to bring water to its 25,000,000 gallon reservoir, north of Jarilla, on Baird hill. —— The St. Louis Copper Co., which has a lease and option on the By Chance mines, near Jarilla, has its shaft down 400 feet. As soon as electric power can be had an electric hoist and drills are to be put in.

Socorro County.

The Mine Development Co., in the Magdalena district, has a plan to connect their Tip Top tunnel with the Key tunnel, thus giving the Key ore an outlet on the west side of the range. The ends of the tunnel are 950 feet apart. —— In the Cooney district work is to be resumed on the Deadwood mine and a cyanide plant is to be put on the Confidence by the Helena M. Co.

OREGON.

Baker County.

At the Mayflower mine in the Cornucopia district the Stampede M. Co. is putting up a new mill and intends building a 42-foot tramway from mine to mill. The ore will be crushed in cyanide solution and amalgamated by passing over copper plates. Then it will pass through classifiers separating the slimes from the sands, the slimes being at once deposited to the bottom of a 16x16 tank. The sands are then passed over Frue vanners, being discharged into 20x5 percolation tanks. The overflow solution from both percolation and slime tanks is discharged to the bottom of an additional 16x6 slime settling tank, the bottom of which is connected with a suitable pump for throwing the solution back to the battery supply tank. The overflowing solution from the slime settling tanks passes through a clarifying box, the compartments of which are filled with excelsior, which clarfies the solution so that it may be passed through zinc boxes when desired, or discharged directly into sump tanks, which tanks are connected with a clear solution pump pumping the clear solutions to the vanner supply tanks. The slimes are treated by agitation and decantation in the 16x6 tanks into which they are discharged from the spitzkasten, and the sands are treated by percolation. The concentrates, which consist principally of telluride of gold and silver, are treated separately by agitation and decantation. G. W. Boggs is manager.

Curry County.

The Chetco M. Co. has been formed, with T. H. Gillham as manager, to work seventeen claims on Chetco creek, near Chetco, and 20 miles from tide water.

Douglas County.

The Bohemia Smelting & Railway Co. has been incorporated at Portland by A. D. LeRoy, H. Daniel, J. W. Sherman, W. G. Woodruff and J. B. Keefer. The objects are to operate mines and a smelter and to build electric lines in the Bohemia district.

Josephine County.

The Oroville Dredging Co. of California has done considerable prospecting of placer and dredger ground on Applegate and Illinois rivers, near Grants Pass, under the direction of Manager Hanford. As a result they have already bought the Vroman and Bird's Eye ranches. —— Down Rogue river, some 45 miles from Grants Pass, the Gold Bar M. Co. is making preparations to start hydraulicking with water from Foster creek. —— Manager A. C. Hoofer of the Mt. Pitt mine, near Grants Pass, has opened the main vein in the lower crosscut, 210 feet from the portal.——The Whitehead & Willeke placer ground on Grave creek, near Leland, is to be worked by W. A. Krum and G. P. Furman.

The Hammersly mine has closed. W. H. Osgood of Seattle has a bond on the property and did considerable work under its terms before closing. The mine is located at the head of Jump-Off-Joe creek, near Grant's Pass. A shaft is down over 200 feet.

SOUTH DAKOTA.

Custer County.

The Ivanhoe mill near Custer is crushing ore from the 250-foot level of the mine.

Lawrence County.

The main tunnel of the Homestake Extension near Deadwood has been driven 800 feet. Manager C. E. McHugh contemplates putting up a stamp mill.

Pennington County.

Tungsten-bearing ore is said to have been discovered in the Bagdad district, 3 miles to the southeast of Keystone, by Ed. Christerson.——A cyanide plant is being put in at the Standby mine at Rochford, and ten stamps of the 60-stamp mill are to be started soon. The main tunnel has been driven 1410 feet, and a 450-foot raise has been made.

UTAH.

Beaver County.

A 25 H. P. gasoline hoist is being put in at the Burning Moscow mine, at Shauntie, by Manager M. Cullen. Sinking is to be continued.

Juab County.

In the double-handed drilling contest at Eureka on Labor Day, H. R. Kelly and R. Leroy of Park City drilled 32⅜ inches; J. Nancarrow and E. Eplett of Eureka 31⅛ inches, and I. Novack and C. Holmes of Eureka 27½ inches.

President H. G. McMillan of the Star Con. M. Co. of Eureka reports that the shaft is 740 feet deep in a lime formation on the 400 level, where some work is being done.——The ore shipments from Tintic district for the week ending Sept. 7 amounted to 114 carloads, produced by the following mines: Eagle & Blue Bell, 12; Centennial-Eureka, 47; Eureka Hill (leasers), 2; South Swansea, 1; Swansea, 4; Yankee Con., 3; Uncle Sam Con, 5; Godiva, 6; Bullion-Beck, 1; Gemini, 10; Victoria, 8; Grand Central, 3; Mammoth, 10; Carisa, 2; concentrates —Uncle Sam mill, 2.

Piute County.

The Sevier Con. M. Co. of Kimberley will use electricity in its new mill. Manager R. W. Foster has located water rights in Clear Creek canyon, 7 miles from the millsite. This is to be the location of a new power plant of 300 H. P. capacity.

Salt Lake County.

The Shawmut property in Carrs Fork, near Bingham, is being opened up preparatory to inspection. F. A. Darrenouge is superintending the property and work has been started in the Cuba tunnel.——The Wall mill has begun the treatment of ores from the Silver Shield. ——The Utah Copper Co. has made connections with the workings of the Ohio Copper Co. through a 2400-foot drive from the main tunnel of the Utah. D. C. Jackling and associates have an option on the Ohio.—— Manager G. G. Hall of the Congor mine of Bingham reports that the mine will soon be unwatered.

Summit County.

At the Ontario drain tunnel, at Park City, the drift which is being run around the last cavein is going parallel with the main tunnel. The drift was sent off at an angle for 54 feet, and now it is expected that it will be run parallel with the tunnel for 350 feet. Every precaution is being taken for the safety of the workmen, and though it will take some time, there is no question about the big drain being opened up again and work resumed at the mine. Water has been reached in the 1100-foot level in the shaft.——At the Harwood property the new whim is in place and sinking on the vein continues. The shaft is down 100 feet.——Ore shipments for week ending Sept. 9 were: Silver King, 1,305,840; Daly-West, 1,125,000; Clegg Brothers, 183,000; Kearns-Keith, 57,000.

Tooele County.

The Cyclone shaft at Stockton is down 650 feet and sinking is being continued by Superintendent F. H. Muhlenbrook.——The Honerine mill at Stockton has been closed down and will probably remain down until the drain tunnel and mine are connected, which may be within three months. For a number of months the plant has been running on tailings left from an old mill operated at Stockton in the early days.

WASHINGTON.

Snohomish County.

(Special Correspondence).—Part of the machinery for the 50-ton concentrator at the Washington Zinc Co.'s mine has arrived at Arlington. —— The Mineral City Power & Transportation Co. has been organized to build an electric road between Index on the Great Northern Railroad and Mineral City in the Silver Creek mining district, and expect the line will be completed within fourteen months. It will be 13 miles long. The president is O. O. Roland; vice-president and treasurer, W. J. McAllister; secretary, C. M. Baker.

Everett, Sept. 10.

FOREIGN.

ARGENTINE REPUBLIC.

A. C. Ross, English Consul at Buenos Ayres, reports that no gold has been won by dredging in the Argentine Republic. A number of companies have been floated in Buenos Ayres to work on rivers in the Argentine, in Chile and in Brazil. Several of the companies have imported dredgers, and in the course of this year results ought to appear. Reports made by New Zealand mining engineers state that there are good prospects of large returns from the rivers. On the Bolivian rivers the average results of numerous tests were from 40 cents to $1.20 per cubic yard. In Tierra del Fuego (Chile) the average of fifty-six bores was 16 cents per cubic yard of stuff moved.

AUSTRALIA.

Queensland.

A subsidy of £2500 is to be granted by the Queensland Government toward the cost of sinking a bore at Roma in search of oil. As natural gas has been obtained it is reasoned that petroleum exists. —— The minerals other than gold, coal or precious stones won for the quarter ended June 30, 1905, were as follows: Copper, 1975½ tons, valued at £130,636, compared with 944 tons, value £45,273; silver, 144,866 ounces, value £15,743, compared with 172,685 ounces, for £18,618; lode tin, 662¾ tons, value £44,992, compared with 663 tons, for £42,103; alluvial tin, 382 tons, value £31,617, compared with 441 tons, for £33,829; lead, 541⅜ tons, value £6856, compared with 530 tons, for £6227; wolfram, 374¼ tons, value £25,283, compared with 297 tons, for £31,477; bismuth, 1½ ton, value £565, compared with 2 cwts., value £50; molybdenite, 2¾ tons for £342, compared with 2 cwts. for £10; manganese, 501 tons, value £2004, compared with 185 tons for £738; bismuth and wolfram, 1¾ ton for £321, compared with 16 cwts. for £80; ironstone, 950 tons, value £687, compared with 640 tons for £244; scheelite, 1½ ton, value £128, compared with 3½ tons, value £300; limestone, 4980 tons, value £3253, compared with 3605 tons for £1971; total value, £262,327, compared with £189,920 for the same period of last year. The exports of silver, copper and lead during the first six months of the year show a net increase of £205,104, as compared with the corresponding period in 1904. The exports of silver, silver-lead, etc., show an increase in value of £255,478, and the output for the year bids fair to be the largest during the past decade. The value of the coal exported is less by £22,621. The shipments to Australian ports show an increase of £26,490, but against this the quantity dispatched to other ports exhibits a falling off in value of £49,111. In copper and tin there was a decrease of £9245 and £18,508 respectively in value. The value of the copper and tin ore imported into the State during the half-year for treatment was £21,175 and £87,005 respectively.

Victoria.

The Mining Journal reports that considerable interest is being evinced in an invention aiming at the effective and economic treatment of battery tailings and slimes. Recently a test was made in a vat 20 feet in diameter and 7 feet in height, and the material operated upon consisted of thirty tons of beach sand, with thirty-five tons of water. The principle of the apparatus consists of two vertical deflecting plates placed almost opposite one another, worked in combination with propellers enclosed

in a cylinder. The propellers are of the augur type, and move freely within the cylinder. The cylinder is raised from the bottom of the vat according to the nature and character of the material to be treated. From beneath the cylinder is projected a strong current of water, the force of which disturbs the mass on the bed of the vat. With a driving power of 20 H. P., seventy revolutions per minute are obtained by the propeller, which was sufficient to give a continuous and perfect movement to the whole of the charge. In the demonstration the material was thoroughly mixed within five minutes of the work being started. When in motion the whole of the contents of the vat, both solid and liquid, were brought into a uniform condition. The apparatus is the invention of a Melbourne resident. A ingenious tin-saving appliance has been invented in Melbourne. Its main feature is a longitudinally divided sluice box, provided with a series of transverse wells, in each of which works an archimedian screw carrier. Farther down the sluice is a revolving grating, overlying a subsidiary sluice, also provided with one or two similarly constructed wells and carriers, and with a transverse sloping lip, which causes the carrier to be continuously submerged. In operation the mixed ore material and water pass down the main sluice, depositing the finer and heavier material in the transverse wells. The revolving action of the screws has the effect of keeping the material in motion, thus assisting concentration, and at the same time conveying the concentrates into the clear water sluice which runs parallel to the main sluice. In this clear water sluice the product is still further reduced by sluicing, and the concentrates are allowed to escape into a launder by means of a slot in the bottom of the wells underlying the end of the clean water sluice.

CANADA.

The Ontario government has issued a report showing an increase during the first half of the year in every mining and steel business carried on in the Province. The total yield is valued at $6,529,728.

	Quantity.	Value.
Gold, ounces	2,930	$25,093
Silver, ounces	1,128,212	595,974
Nickel, tons	4,671	1,638,040
Copper, tons	2,256	335,637
Cobalt, tons	65	80,560
Iron ore, tons	113,583	274,224
Pig iron, tons	116,794	1,510,197
Steel, tons	64,527	2,070,003
Total		$6,529,728

Practically all the silver, all the cobalt and thirty-two tons of the nickel were produced in the newly-discovered mines at Cobalt, Temiscaming district. The quantity of ore shipped from these deposits during the half year was 891 tons and the value $684,879, so that the average value realized for the ore as shipped was $768.66 per ton.

BRITISH COLUMBIA.

The returns of the lead production in British Columbia for the fiscal year beginning July 1, 1904, and ending June 30, 1905, are as follows:

	Lbs Lead.	Bounty.
Nelson smelter	16,421,071	$116,709 1
Trail smelter	13,446,086	96,684 36
Unclaimed	7,599	51 84

Including claims paid at another smelter, the totals for lead produced and treated in Canada are 33,730,546 pounds of lead and $240,288.90 bounty. The amount of lead exported was 21,972,988 pounds, on which the bounty paid was $96,697 37. The grand total for the year, therefore, is 55,703,534 pounds of lead produced and $336,986 37 paid in bounty. The leading producers and bounty earners in order are: St. Eugene, North Star, Slocan Star, Ivanhoe, Idaho, Payne, Paradise, Silver Cup, Enterprise, Lucky Jim, Silver Hustler, Ymir and Triune.

Vancouver Island.

The Cordillero M. Co. of Seattle, Wash., of which Alfred Raper is manager, has bonded the Cornell mine on Texada island and work has recommenced. The 32 H. P. boiler is being put in and the air line is being connected with the Copper Queen mine. The upper levels are being cleaned and the lower levels are to be pumped out. The shaft is down to the 500-foot level.

Boundary District.

A large body of low-grade ore is reported as having been struck in the 250-foot level of the new shaft which has been sunk on the Last Chance mine of the Republic group at Smith's camp, west of Boundary Falls. W. T. Smith is manager.——It is reported that work will be resumed on the Preston in Skylark camp.——At the Elkhorn a new shaft is being sunk. Recently the Elkhorn was incorporated as the Boundary-Elkhorn Mines, Ltd., P. McDonald and J. Sutherland of Greenwood being the chief owners.——The Jewel mine in Long Lake camp has resumed operations after a several years' shutdown. J. H. Smith is in charge.

East Kootenay District.

Development of the Aurora mine at Moyie is said to show ore running 40% zinc.

West Kootenay District.

At the Canadian smelting works at Trail another gold-copper furnace will be added to the present equipment. There are already four copper furnaces, with a combined capacity of 1000 tons a day. The smelter is now receiving about 4000 tons a week from the mines of Rossland and from 100 to 200 tons a week from Larson, Idaho. The Le Roi will send a little over 2000 tons a week at the start. The new furnace will reduce 250 tons a day, which will give a total capacity of 8750 tons a week for the five furnaces.

MEXICO.

The Chihuahua Enterprise states that the American Smelting & Refining Co. has the smelter at Aguascalientes with a capacity of 2000 tons daily, and one at Monterey with 1000 tons. The tonnage of the independent smelters in operation is shown by the following: At Santa Rosalia, Lower California, the Companie du Boleo, a French company capitalized at 12,000,000 francs, is operating a smelter of 1200 tons daily capacity. This plant produced last year 22,466,000 pounds of fine copper. The Copete M. & S. Co., at El Copete, Sonora, has a smelter of 200 tons capacity. The Democrata M. Co., La Cananea, Sonora, has a furnace of 125 tons daily capacity and is producing 3,750,000 pounds of copper per annum. The Descubridora M. & S. Co., now closed down, has a 600-ton smelter near Mapimi and a 200-ton plant at Conejas. The Compania de Pinoles, of Mapimi, has a capacity of 1000 tons per day, employing 3000 men. The Yaqui Smelting & Refining Co., San Antonio de la Huerta, Sonora, has a new furnace of 125 tons daily capacity, which is supplemented by a concentrating plant, making a total capacity of 250 tons daily. The Moctezuma Copper Co., a branch of Phelps-Dodge Co., has a 300-ton smelter and a 600-ton concentrator at Nacozari, Sonora. At present only the concentrator is being operated and the concentrates are shipped to the Copper Queen smelter of the same company at Douglas, Ariz. The Greene Consolidated Copper Co., consolidated with Phelps-Dodge interests, has a smelter of 2000 tons daily capacity which is supplemented by a concentrating plant of 2600 tons capacity. Over 4000 men are employed. For the year ending July 31, 1905, the company produced 63,005,848 pounds of refined copper, 399,270 ounces of silver and 3790 ounces of gold, worth $9,768,000 gold. The Douglas Copper Co., Alamos district, Sonora, has a smelter of 250 tons capacity. The Mazapil Copper Co., Ltd , has a 500-ton smelter at Saltillo and a small furnace at Concepcion del Oro, and is producing 6,000,000 pounds of copper per year. The Compania Metalurgica, at San Luis Potosi, employs 1000 men and operates a copper and lead smelter of 1000 tons capacity, doing a custom business. The Mitchell M. Co., Chilpancingo, Guerrero, has a 200-ton furnace and will add more. The Monterey Smelting & Refining Co., Monterey, N. L., has a plant of 1500 tons capacity. The Compania Metalurgica de Torrean has a capacity of 1000 tons daily and is to have two copper furnaces of 250 tons each. It is currently reported that the smelter trust is negotiating for the purchase of the plant. In addition to the foregoing there are thirty-six small plants of from 25 to 250 tons capacity each, or an average of 85 tons each, having a total capacity of 3100 tons in actual operation, besides those that have been closed down. There are several others in course of construction, aggregating 1000 tons daily capacity. In the past few months there have been several concessions granted for smelters in various parts of the republic, among which are one at Naco, Sonora, one at Durango, one each at Jimenez and Parral, Chihuahua, aggregating perhaps 1000 tons capacity daily. The plant at Santa Rosalia is to be increased from 80 to 300 tons daily, and the owners say it is to be made 800 tons.

Aguas Calientes.

The Con. Tin M. & S. Co. is working a tin mine 30 miles from Aguas Calientas. W. A. Pratt and W. H. Foster are interested.

Baja California.

(Special Correspondence).—New machinery is being put in at the Aurora and Princess mines at Alamo by Superintendent G. W. Russell.——The smelter of the Esperanza M. Co. has been blown in on Cedros island by D. A. Crowley, who has returned to San Francisco.——The machinery for the electrolytic copper reduction plant at Julio Cæsar camp has arrived at Punta-Canvas, on the mainland. G. P. Brown is general manager.

San Diego, Cal., Sept. 11.

Chihuahua.

The output of the mines of Santa Eulalia, as shipped to the smelters during August, was about 27,980 tons. The Buena Tierra mine of the Santa Eulalia Exploration Co. shipped 5500 tons; Chihuahua Potosi Co., 16,000 tons; Galona, 2750; Mina Viega, 2200; Juarez, 1000; Eureka M. Co., 100; Dolores, 100; San Juan M. Co., 30; other shippers, 300. The Juarez mine of Manuel Gameros and Juan Trevino has been producing but a short time.

The output of the mines of the Parral district, including Santa Barbara and Minas Nuevas, was 22,993 tons of ore, of which 13,098 tons were shipped to the various smelters and 9895 tons were treated locally. The output of Santa Eulalia was 27,980 tons. Of this amount the Chihuahua M. Co. and the Potosi M. Co. shipped 16,000 tons; the Buena Tierra, 5500 tons; the "trust" mines, 4950 tons and the Juarez mine, 1000 tons.——The Pinos Altos M. Co. at Pinos Altos has remodeled the old 60-stamp mill and changed the process from amalgamation to cyanide and concentration. Twenty stamps are now in operation and will be regularly producing from now on. The company expects to enlarge the plant. The regular monthly shipment amounted to $90,000.——Lluvia de Oro has now a 20-stamp mill in operation and sent out gold bullion to the value of $120,000.

Sonora.

The Veta Grande property, formerly owned by N. S. Finch, is under bond to J. Galey of the United States Steel Co., and development work is being pushed, forty men being employed under the supervision of A. Houle. A three-compartment shaft is being sunk on the principal ore body and will go down 600 feet. The property is in the Arispe district, 9 miles from Bocoache.

The Richfield M. Co., in the Ures district, 12 miles east from Tuape, has ordered a double-reel hoisting engine, with a capacity for sinking 1000 feet. As soon as it is in operation the double-compartment shaft, now at a depth of 300 feet, will be carried down to the 1000-foot level. Arrangements are to be made for a concentrating mill with a capacity of fifty tons of ore daily. A road is to be built between Querobabi station and the camp, 37 miles.

Obituary.

VERNON H. ROOD, vice-president Jeanesville Iron Works Co., died in Bad Neuheim, Germany, Sept. 1. His death is deplored by many friends and business acquaintances.

Personal.

D. R. REED has returned to Ouray, Colo., from Denver, Colo.

E. R. ABADIE is superintendent Baltic shaft, Randsburg, Cal.

A. W. BRATTUND has charge Ward mill at Idaho Springs, Colo.

HERMAN DAVIS has returned from San Francisco, Cal., to Dayton, Nev.

H. W. TURNER of Terlingua, Tex., is examining Idaho mining property.

S. H. COX is professor of mining at the Royal School of Mines, London, Eng.

S. A. HARSH, Denver, Colo., is in San Francisco, Cal., looking after mining interests.

R. B. STANFORD, formerly of Columbia, Cal., is now at Bluefields, Nicaragua, C. A.

V. SHERWOOD is manager new 100-stamp mill Guanajuato G. M. Co., at Guanajuato, Mexico.

L. S. AUSTIN, professor of metallurgy in the Michigan College of Mines, is visiting New York.

A. A. BERNAUD of Colorado has been appointed superintendent Dairy Farm mine, California.

JOHN CARKOL is superintendent Sidewinder mine, at Victorville, San Bernardino county, Cal.

S. E. LAKE is superintendent Dragoon Mountain M. Co., near Dragoon, Cochise county, Ariz.

A. C. REDDING is superintendent Monumental Mines Co., at Monumental, Del Norte county, Cal.

EX-LIEUT.-GOV. JOHN DAGGETT has returned to Siskiyou county from a San Francisco visit.

N. H. MURRAY has charge cyanide plant San Felipe M. Co., near Hostotipaquillo, Jalisco, Mexico.

W. B. LADD of Madison, Wis., has been appointed manager Ophir Con. M. Co., at Telluride, Colo.

F. C. PFEIFER, a mining man of Esmeralda county, Nev., is in San Francisco, Cal., on mining business.

W. C. RALSTON, president Fulton Iron Works, has returned from Denver, Colo., to San Francisco, Cal.

S. J. GORMLEY has succeeded W. H. Mulling as superintendent Bingham Con. smelter at Bingham, Utah.

E. C. HOLMES, manager San Juan mine, at Santa Eulalia, Chihuahua, Mexico, is in San Francisco, Cal.

O. P. ANKENY has been appointed mine superintendent Gilt Edge Maid M. Co., working near Galena, S. D.

SAMUEL PARNALL, superintendent Calumet & Arizona mine, at Bisbee, Ariz., has been at Calumet, Mich.

R. B. BRINSMADE has been elected to the chair of mining in the New Mexico School of Mines, at Socorro, N. M.

R. J. GRANT, on his return to Colorado from Western Australia, is spending a few weeks at Greenville, Nova Scotia.

W. P. THOMPSON is manager reorganized Waterson G. M. Co., Ltd., operating near Ocampo, Chihuahua, Mexico.

W. N. FREDERICK has been appointed superintendent Richfield M. Co., operating near Tuape, Sonora, Mexico.

M. F. PERRY, manager Charles Butters Co., at La Colorada, Sonora, Mexico, has returned from a visit to San Francisco, Cal.

J. G. HARDY, general manager Dolores M. Co., at Minaca, Chihuahua, Mexico, has returned to the mines from a trip to Japan.

W. R. THOMAS, superintendent Central Eureka mine at Sutter Creek, Amador county, Cal., is said to have resigned because of illness.

JAS. HARTGERING has been appointed manager Dakota M. & M. Co. of Deadwood, S. D. N. I. Leydig will be mill superintendent.

H. E. CRAIN, representing the United States Geological Survey, is in Wyoming investigating the platinum deposits on Pliny creek, 35 miles north of Sheridan.

C. T. DURELL, manager St. Paul-Montana M. Co., operating the Spotted Horse mine at Maiden, Mont., has returned from a directors' meeting in St. Paul, Minn.

L. D. RICKETS has been appointed general manager Greene Con. Copper Co. of Cananea, Sonora, Mexico, reported to have been consolidated with Phelps-Dodge interests.

H. A. SHIPMAN, formerly manager of Stratton's Independence at Cripple Creek, Colo., leaves Western Australia in November and will return home by way of San Francisco, Cal.

AUGUSTE MATHEZ AND W. B. ROGERS, both of Salt Lake City, Utah, are examining copper deposits in Concurrie district, north of Brisbane, Australia, for Samuel Newhouse.

G. J. MCCARTY, general manager Creston-Colorada M. Co., has returned to La Colorada, Sonora, Mexico, from a trip to Chihuahua, City of Mexico, San Francisco and Denver. He had been absent since May.

FRANK S. CRONK, for the past year manager of the advertising and publicity department of the Colorado Iron Works Co., Denver, Colo., has resigned to accept a similar position with the Fulton Iron Works Co., San Francisco, Cal.

Commercial Paragraphs.

THE Redwood Mfg. Co. will erect a new $50,000 concrete building for its Oakland, Cal., tank department.

THE Fulton Iron Works of San Francisco, Cal., is sending a $100,000 stamp mill to the Lookout mine, Oasis, Nev.

THE S. H. Supply Co., Denver, Colo., report the sale of a four-drill American compressor with boiler and drills to Durango, Mexico, also a No. 2 Wild mill, with 50-ton concentrating plant, to California and a No. 2 Wild mill to New Mexico.

A BYRON JACKSON centrifugal pressure electric pump has been put in on the 400-foot level of the Old Ironsides mine, Phœnix, B. C. It has a 300-gallon per minute capacity against a 500-foot head and is operated by a 75 H. P. Westinghouse motor. The office of the Byron Jackson Co. is 411 Market St., San Francisco, Cal.

THE Raymond Con. M. Co., Ohio City, Colo., have contracted with the Colorado Iron Works Co., Denver, Colo., for a mill of twenty 1050-pound stamps, chrome steel to be used in all the mill parts; the amalgamating plates 12 feet long, in two sections; capacity 100 tons per day, power to be supplied by a 150 H. P. Skinner engine. The Colorado Iron Works will erect the complete plant, including the mill building.

THE Chicago House Wrecking Co., Thirty-fifth and Iron streets, Chicago, Ill., bought most of the Louisiana Purchase Exposition and are offering the material, etc., for sale. They bought everything within the grounds, including the fence, except a few of the foreign and State buildings. This company is the largest one of its kind in the world and has an organization that enables it to handle such gigantic operations as wrecking and selling world's fairs. A great deal of the material is illustrated in the new catalogue, No. 142, which will be sent on application.

ARMSTRONG BROS. TOOL CO., large manufacturers of tool holders, are in their modern factory at 104 North Francisco Avenue, Chicago, Ill. This concern has been progressing rapidly since their organization twelve years ago. The new factory is 60x175 feet, three floors and a basement, and is of modern mill construction. The basement has concrete floors, and the lighting facilities are of the best. Considerable new automatic machinery has been installed and the company is in good shape to handle their growing business. A new eighty-page catalogue will be sent to anyone on request.

THE Japanese army has rebuilt the city of Dalny, using Malthoid roofing, which has been used extensively by the Japanese Government for several years, finding it to be durable, long-lasting, convenient and inexpensive for army use. The compactness and ease with which it can be transported, together with the fact that all of the necessary nails, cement, tin caps and directions are contained in each roll enabled the Japanese army to quickly, inexpensively, and thoroughly re-roof the buildings that had been partially destroyed by fire and the devastation of war. Samples and booklets are furnished by The Paraffine Paint Co., 24 Second street, San Francisco Cal.

UNDER date of the 7th inst., the New York Sun says: Alton B. Parker, as referee, has reported to the Supereme Court that the John A. Roebling Sons Co. is entitled to a judgment of $231,081, with interest from December, 1902, for work done in the construction of the new Williamsburg bridge. From the amount claimed by the Roeblings fines at the rate of $1000 a day were deducted by the bridge commissioners for failure to complete the bridge contract time. The total value of the contract awarded to the company was $1,398,000. Judge Parker holds that the failure of the Roeblings to finish their part of the work was not due to any fault of theirs, but to obstacles which were placed in the way of the contractors by city officials.

THE Union Gas Engine Co. of San Francisco, Cal., will install Union engines of 300 H. P., running on crude oil, in the Pacific Coast Oil Co.'s barge No. 4. These engines are of the same size and type as those recently installed in the lumber schooner Argus, property of the Pacific Shipping Co., San Francisco; the lumber schooner Sotoyome, property of the Albion Lumber Co., San Francisco, and the Alaskan passenger boat Anvil, property of the John J. Sesnon Co., San Francisco. The German Government schooner Ponape, and the schooner Oakland, property of Hunt, Hatch & Co., San Francisco, were recently equipped with Union engines of this type. The Union Gas Engine Co. will soon enlarge its facilities, having purchased nine acres with a frontage of 350 feet on the Oakland, Cal., estuary, with a depth of water of 12 feet at low tide.

THE J. Geo. Leyner Engineering Works Co., Denver, Colo., report recent air compressor sales as follows: Asiatic T. & M. Co., Colo., two ten-drill compressors; Waldorf M. & M. Co., Colo., two eight-drill compressors, electric driven; American S. & R. Co., Utah, cross-compound; Southwestern B. & I. Co., Colo., complete plant with tandem compound, ten-drill compressor; F. C. Miller, Mont., belt-driven compressor; Denver G. & E. Co., Colo., tandem compound; Prescott Engineering Works, Ariz., duplex; Denver & Rio Grande Railway (Colo. 1, Utah 1), two steam actuated, two-stage, of 1000 cubic feet capacity each; Mountain C. Co., Cal., belt-driven, four-drill; United States Reclamation Service, tandem, compound; Japanese Government, electric driven; Kansas City Southern Railway, La., steam, straight line; Blue Flag M. Co., Colo., eight-drill, steam actuated; Denver Iron & Wire Works Co., Colo., electric driven; Consolidada de Construcciones Metalicos Mexico, electric driven; Newark M. & M. Co., Nev., two-drill, steam; Centennial Coal Co., Colo., two-stage, steam. The company reports its new factory completed and machinery now being installed by degrees without interference with its production.

Trade Treatises.

"Hoisting and Conveying Machinery for Power Stations," Bulletin No. 12 of Robins Conveying Belt Co., Park Row Bldg., New York City, gives an interesting illustrated exposition of the construction and use of the belt conveyor, giving emphasis to its utility in handling fuel.

The Sullivan Machinery Co., Railway Exchange, Chicago, Ill., describe the Sullivan automatic cross-over dump in Bulletin 48E. This is designed for the rapid and economical handling of cars from mines and quarries.

"Link-Belt Car Hauls" is an illustrated booklet from the Link-Belt Machinery Co., Chicago, Ill., showing the advantages of this system in the economical handling of material.

The process of washing coal for coke or fuel is admirably detailed by text and pictures in Booklet No. 42 of the Link-Belt Machinery Co., Chicago, Ill., "Washing Bituminous Coal."

Books Received.

As extracts from "Mineral Resources of the United States," the United States Geological Survey has issued "The Production of Quicksilver in 1904," "The Production of Fuller's Earth in 1904," and "The Production of Antimony in 1904," by E. O. Hovey.

Latest Market Reports.

SAN FRANCISCO, September 15, 1905.

METALS.

SILVER. — Per oz., Troy: London, 28 1/16d (standard ounce, 925 fine); New York, bar silver, 62c, refined (1000 fine); San Francisco, 62c; Mexican dollars, 48c, San Francisco; 47c, New York.

COPPER.—New York: Standard, $16.37½; Lake, 1 to 3 casks, $16.00@16.25; Electrolytic, 1 to 3 casks, $16.75; Casting, 1 to 3 casks, $15.75@16.25. San Francisco: $16.50. Mill copper plates, $17.50; bars, 18@24c. London: £68 17s 6d spot per ton.

Following are the figures of German consumption of foreign copper for the months from January to July, 1905, as compared with the same period of time for 1904 and 1903:

	1905.	1904.	1903.
Imports, tons	63,453	64,334	49,263
Exports, tons	7,289	4,814	6,283
Consumption, tons	56,164	59,520	42,980

Out of the above, 53,914 tons were imported from the United States.

LEAD.—New York, $4.90; Salt Lake City, $3.50; St. Louis, $4.52½; San Francisco, $3.70, carload lots; 4¼c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5¾c; pig, $4.85. London: £14 6s ℔ long ton.

SPELTER.—New York, $5.85; St. Louis, $5.65; London, £26 ℔ ton; San Francisco, ton lots, 6¾c; 100-lb lots, 7c.

TIN.—New York, pig, $32.00@32.10; San Francisco, ton lots, 34c; 500 lbs., 35c; 200 lbs., 35½c; less, 35½c; bar tin, ℔ lb., 35@37½c. London, £145 10s.

PLATINUM.—San Francisco, crude, $18.50 ℔ oz.; New York, ingot, $20.50 ℔ Troy oz. Platinum ware, 75@$1.00 ℔ gram.

QUICKSILVER.—New York, $40.00@40.50, large lots; London, £7 2s 6d; San Francisco, local, $38.50@39.00 ℔ flask of 75 lbs.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 32½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 22.00c; San Francisco, Plumbers', 100-lb. lots, 19.15c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb, .04c.

NICKEL.—New York, 55@60c ℔ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 33@37c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c ℔ lb.; 100 lbs., 35c; 1000 lbs. 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $15.00; gray forge, $16.00; San Francisco, bar, 3c ℔ lb., 3¼c in small quantities.

STEEL.—Bessemer billets, Pittsburg, $21.00@$23.00; open hearth billets, $23.00@$24.00; San Francisco, bar, 7c to 12c ℔ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 7¾c; less than 500 lbs., per lb., 8c; in 25-lb. tin pails, ½c ℔ lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LIME.—Santa Cruz, $1.35 country, $1.25 city ℔ bbl.

CEMENT.—Imported, $3.00@4.00 ℔ bbl.; California, carload lots, $1.80 f. o. b. at works; small lots, $2.10 ℔ bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

LUMBER.—(Retail): Pine, ordinary sizes, $24.00@5.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50@5.00; pickets, $21.00; shingles, $2.50 for No. 1, and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00@35.00.

NAILS.—This week the basic prices are: Wire, $2.77; Cut, $3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d, Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4d and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 13½c; Hallett's, 14½c; San Francisco, 1000-lb. lots, 14c; 300@500-lbs. 12c; 100-lb. lots, 13c.

BISMUTH.—Subnitrate, ℔ lb., $2.10.

BONE ASH.—Extra No. 1, 5@6c ℔ lb; No. 1, 4@5c.

BORAX.—Concentrated, 7@8c ℔ lb; powdered, 9@10c; fused, 25@30c; crystal, 7c.

CANDLES.—Spear Brand, 16 oz. adamantine, 40s., 11c ℔ set; 14 oz. adamantine, 40s., 10c; 12 oz. adamantine, 40s, 9c; 10 oz. adamantine, 40s, 8c; 16 oz. stearic, 40s, 12½c ℔ set; 14 oz. stearic, 40s, 11½; 12 oz. stearic, 40s, 10½c; 10 oz. stearic, 40s, 9½c. 100-case lots and over, ½c less. Not less than 50-case lots, ¼c less. Boxes of 20s, price ½c advance.

CAPS.—3x, $5.50@6 per 1000; 4x, $6.50@7; 5x, $8@8.50; Lion, $9@9.50, in lots not less than 1000.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c ℔ lb.; caustic soda, in drums, 3@3½c ℔ lb.; Cal. s. soda, bbls., $1.10@1.20 ℔ 100 lbs.; sks., 90c@$1.00; chlorate of potash, 12@13c; nitrate of potash, 6½@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2½@2¾c; flour sulphur, French, 2¾@—c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 5½@5¾c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66% B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

CHROMIUM.—90% and over, ℔ lb., 80c.

COAL.—San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lot, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $8.50, long ton; Colorado Anthracite, $14.00. Coke, $10.50 per ton in bulk, $13.00 in sacks; Sunnyside, $8.50, long ton.

FIRE BRICK.—Domestic, carloads ℔ 1000, f. o. b., factory square, $25.00; soap and split, $22.50; arch and wedge, $27.50; skewback, $30.00; circle, $32.00.

FIRE CLAY.—Domestic, ℔ ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, $8.50.

FUSE.—Triple tape, $4.00 per 1000 feet; double tape, $3.50; single tape, $3.10; Hemp, $2.75; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 and up.

OILS.—Linseed, boiled, bbl., 58c; cs., 63c; raw, bbl., 56c; cs., 61c; Lucol oil, boiled, bbl., 51c; cs., 56c; raw-bbl., 49c; cs., 54c. Kerosene—Pearl, per gal., 17½c; Astral, 17½c; Star, 17½c; Extra Star, 20½c; Eocene, 19½c; Elaine, 26c; Water White, in bulk, 11c; Mineral Seal, iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 14½c, do., cs., 21c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 12½c; do., in cs., 19c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 68c; Bleached, do., 57c; Whale Oil, cs., 52@67c.

LITHARGE.—Pure, in 25-lb. bags, 9½@10½c ℔ lb.

MAGNESIUM.—Pure, N. Y., $1.60.

MANGANESE.—Black oxide, ℔ lb., 2¾@4c.

MERCURY.—Bichloride, ℔ lb., 77c.

MOLYBDENUM.—Best, $2.75 ℔ lb.

PHOSPHORUS.—American, ℔ lb., 70c.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1**, 50%, carload lots, 11¾c; less than one ton, 13¾c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2**, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

RED LEAD.—500 lbs. and over at one purchase, ℔ lb. 7½c; less than 500 lbs., 7¾c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 54c.

SODIUM.—Metal, ℔ lb., $1.

TUNGSTEN.—Best, ℔ lb., $1.20.

URANIUM.—Oxide, ℔ lb., $3.40.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

BALING PRESS.—No. 798,782. Sept. 5, 1905. William H. Gray, San Leandro, Cal. This invention relates to improvements in baling presses, and is especially applicable to vertically disposed presses. It consists in the combination of a vertical press box, a follower, a superposed bale chamber and a vertical arm extending into the bale chamber and a vertical arm extending upwardly above the pivotal point of the lever and against the vertical sides of the press, means for actuating the retainers in series, and a unitary spring connected with the actuating means to normally retain the levers in position.

RAKING AND LOADING APPARATUS.—No. 798,810. Sept. 5, 1905. John R. Lewis, Biggs, Cal. This invention relates to an apparatus which is designed for raking and loading hay, grain, or equivalent material, and by the use of a closed shovel it may also be employed for the digging and lifting of earth or similar material that cannot be handled by a rake. Its object is to provide an apparatus by which material may be gathered, lifted, and deposited at a distant point. The apparatus comprises a wheeled frame and support, a rake or gatherer located at the front, a normally, downwardly and forwardly inclined frame having its upper end connected with the support, a flexible connection with said inclined frame and the rear of the gatherer, and a propelling frame hinged to the gatherer and intermediate between it and the front of the wheeled frame.

HOISTING AND CONVEYING APPARATUS.—No. 798,861. Sept. 5, 1905. Charles J. Allen, San Francisco, Cal. The object of this invention is to provide a simple and portable apparatus that can be quickly and easily rigged up and which is designed particularly for moving loads short distances in vertical and horizontal directions, as in handling material about a building in course of construction and for excavating, loading, or unloading coal and the like, for transferring burdens from a ship to the dock, and vice versa, and generally where it is now usual to employ either a block and tackle or a derrick and boom. The apparatus consists in a combination with end supports of a hoisting rope on one support, a counterbalanced rope on the other support, a block carried by the counterbalanced rope through which the hoisting rope passes, means for reciprocating said block between the two supports, and a spring hook or grab normally disposed at one side of the vertical plane of the ropes and adapted to engage with the counterbalanced rope.

CATALOGUE OF CHEMICAL TECHNOLOGY AND GENERAL CHEMISTRY.

PUBLISHED AUGUST 15, 1905.

☞Our Complete Classified Catalogue of Books on Chemical Technology and General Chemistry arranged under the following heads: Acids, Alkalies, and Salts; Beverages, Brewing, Cider, Distillation, Fermentation, Liquors, Preserving, Vinegar, Wine; Brick, Ceramics, Glass, Porcelain, Pottery; Cement and Concrete; India Rubber, Gutta Percha, Glue, Ink; Leather Manufacture; Oils, Fats, Waxes, Paints and Varnishes; Paper Manufacture, Fibres; Perfumery; Soap and Candles; Sugar, Starch; Flour, Baking, Bread, Confectionery; General Reference and Receipt Books. General Chemistry, Chemical Arithmetic, Calculation, Tables, etc.; Chemical Analysis; Inorganic Chemistry; Organic Chemistry; Electro-Chemistry; Addenda; sent free to anyone in any part of the world who will send his address.

810 Walnut St., Philadelphia, Pa., U. S. A.

DELINQUENT SALE NOTICE.

ALTA SIERRA GOLD MINING COMPANY.—Location of principal place of business, Room 620, Kohl Building, 406 Montgomery street, San Francisco, California; location of works, Sierra County, California.

Notice—There are delinquent upon the following described stock on account of assessment of thirty (30) cents per share, levied on June 22nd, 1905, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Cert.	No. Shares.	Amt.
A. R. Baldwin	67	500	$ 150 00
A. R. Baldwin	68	500	150 00
A. R. Baldwin	69	556	166 80
W. H. Mead	73	4,000	1200 00
W. H. Mead	74	2,000	600 00

And in accordance with law and an order from the Board of Directors, made on the 19th day of August, 1905, so many shares of each parcel of such stock as may be necessary, will be sold at the office of the company, Room 620, Kohl Building, 406 Montgomery street, San Francisco, California, on MONDAY, September 18th, 1905, at 12 o'clock M. of said day, to pay the delinquent assessment thereon, together with costs of advertising and expenses of sale. By order of the Board of Directors.

SAM. W. CHEYNEY, Secretary.

Office—Room 620, Kohl Building, 406 Montgomery street, San Francisco, California.

ASSESSMENT NOTICE.

GOLDEN WEST MINING COMPANY.—LOCATION of principal place of business, San Francisco, California; location of works, Tuolumne County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 19th day of August, 1905, an assessment (No. 5) of one cent per share, was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the secretary, at the office of the company, 307 Battery street, Room 15, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 28th day of September, 1905, will be delinquent, and advertised for sale at public auction; and, unless payment is made before, will be sold on SATURDAY, the 11th day of November, 1905, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.

CHAS. BOVONE, Secretary.

Office—207 Battery street, Room 15, San Francisco, California.

WEALTH IN SIGHT.

The Territory tributary to the

Santa Fe System

In INDIAN TERRITORY, TEXAS, COLORADO, NEW MEXICO, ARIZONA and CALIFORNIA, offers to limited investments of capital, backed by energy and brains, unusual opportunities for development of GREAT MINERAL PROPERTIES.

Deposits of the following are known to exist on and within a few miles of our lines:

Antimony, Alum, Asbestos, Asphalt, Barytes, Bauxite, Borax, Cement Rock, Coal, Cryolite, Clays of all kinds, Copper, Gold, Graphite, Gypsum, Granite, Iron, Kaolin, Lead, Lithograph Stone, Manganese, Mica, Marble, Mineral Paints, Nitre, Nickel, Natural Gas, Onyx, Petroleum, Phosphate Rock, Pumice Stone, Pyrites, Quicksilver, Salt, Silica, Strontianite, Stone—Oolite, Lime and Sand, Silver and Zinc.

For further information, address

WESLEY MERRITT,
Industrial Commissioner,
Atch., Top. and Santa Fe System,
CHICAGO, ILL.

The Lyceum

An excellent preparatory school for the University, Law and Medical Colleges, etc. Begins its thirteenth year on July 24, 1905. Come and be with us; we prepare you well.

Electricity in Mining.

The equipment of a mine is often left to the discretion of the superintendent. He is often a man who has worked his way up through the hard school of experience gained through mistakes, which mistakes he will never again make. But within recent years the progress in mining machinery has been so rapid that few superintendents have been able to keep track of all the latest improvements.

This is particularly so with reference to the application of electricity to mining. When for various reasons a board of directors has voted that an electric hoist or other electric power application be installed at their mine, they usually look to the superintendent to put in an efficient plant at the least possible cost. He is immediately confronted with the problems of deciding whether to use direct or alternating current; single or polyphase circuits; high or low frequency; synchronous or induction motors, and rotary converters or motor generators. In his perplexity he usually consults a number of machinery houses, each of which urges the advantage of their own product, but all tending to confuse him. For a large installation it is undoubtedly best to employ an unbiased electrical engineer to design the installation.

But the progressive superintendent can often solve the problem himself if he make a careful study of the circumstances and conditions under which the plant will be required to operate. The problem is simplified greatly if the mine be within the ever-widening zone of great central generating plants. For in this case one deals only with the motor, and not the dynamo.

The most recent developments in the electric field tend to the use of single-phase alternating current motors for use in hoisting and all variable speed work. This is displacing the direct current machines largely because of the economy effected by the use of the current without preliminary transformation. For mining work this is still in an embryonic stage, but its success in railway work is an indicator of possible usefulness in mining. Consequently developments in this line are being watched with interest by engineers intent upon cost reduction commensurate with efficient service.

SUMMER CAMP OF SURVEYING STUDENTS, UNIVERSITY OF CALIFORNIA. (See Page 207.)

HOW the facts may be juggled and how figures may be mixed up in what are called "statistics," in an effort to prove anything, is strikingly shown in the current issue of a contemporary wherein the argument is made that "oil cannot compete with coal." It is now in order to furnish further data proving that for economy and efficiency the electric light is not in it in competition with the tallow candle.

BUTTE, MONTANA, reports that one of the mines in the Lexington group, heretofore classed as a strictly copper proposition, is developing into a high-class gold mine. Senator Clark's biggest wealth producer, the United Verde, Jerome, Arizona, was originally bought for and worked as a gold mine, later developing into a first-class copper property. The Mountain Copper Co.'s property in Shasta county, California, was first sold as a gold mine, and long believed to be such.

APART from any speculative excitement, the value of the mining industry as an investment proposition is manifest. Much of the present prosperity of the country is because of the permanence and profit of the mining industry. And those words "permanence and profit" are deliberately chosen. A business fifty years old is not usual; a manufacturing or mercantile establishment one hundred years old is phenomenal, but "going" mines that have been profitably productive for hundreds of years are not so uncommon as to excite remark. As a regular, steady, legitimate business, mining stands equally well with commerce, manufactures or agriculture in this present era of prosperity, and when the inevitable period of financial depression rolls round it is to the miner that the whole industrial world looks for immediate relief. For it is he alone who is a creator of wealth. The dollar that he produces makes the world have just that dollar more than it ever had before. The merchant's transaction is but a swap: the manufacturer's product but an assemblage of already created values, the agricultural product but a brief evolution of perishable material, but the product of the metal miner enhances the aggregate of the world's wealth forever.

"Concentrates."

A good many questions are weekly asked this journal; questions involving everything relating to mining or metallurgy, which includes considerable technical matter, engineering, law, geology, etc. Some of these questions are hard to answer, especially in the usual limits of a "Concentrate" in which is accorded the answer. Some of the questions take a long time to answer, for the required information is not on tap, nor can it be had by the mere pressure of a button. Many questions so received have had to journey long distances for solution, for, on the principle that "everybody is wiser than anybody," specialists on different subjects are constantly consulted, and, through the years, there are many men of pronounced p ominence in the mining world who have been courteously requested to answer some of the myriad questions submitted to this journal, and in turn forwarded to them in recognition of their ability or knowledge in that particular line. In this connection gladly indeed is the statement made that almost invariably the requested information has been furnished. Thus through the years have those pages of "Concentrates" become the repository of the very kind of practical, up-to-date information most eagerly sought by live mining men everywhere. Of course, there have been mistakes, for infallibility is an attribute denied to any work of hand or brain, but it is honestly believed that in no other way has so much of practical value been gathered in such concise shape for miners, mining engineers, mechanicians and metallurgists everywhere as in the thousands of "Concentrates" that have appeared since that department was started by the writer in 1894. The appearance of so many similarly worded paragraphs under various names in so many contemporaries is not the least of the numerous testimonials to the recognized value of the work.

Origin of Our Mining Laws.

"An Act granting the right-of-way to ditch and canal owners through the public lands, and for other purposes."

There is nothing in the above that would even remotely indicate that the act, so entitled, covered the location and patenting of a mining claim, but it does, the quoted paragraph being the title of the first law in relation to mineral land ever passed by the Congress of the United States. The real "origin of our mining laws" is the procedure of the California miners "in the days of '49," in the local enactment of mining district regulations. So obscure was the whole matter in the minds of our national legislators that there was no attempt by them to make any law applicable to mines or minerals till the close of the Civil war of 1861-65, when in December, 1864, the Secretary of the Interior in his official report suggested that, as mineral lands were the property of the Government, a revenue tax be laid upon the miners, and that the Internal Revenue Department be invested with power to issue licenses and collect a tax of 1% per annum "on the present product of the mines." That scheme did not meet with approval, and then it was proposed in Congress to "sell all the mineral lands in California and other Western States and Territories" and apply the proceeds to the payment of the national debt. In June, 1865, Congressman G. W. Julian of Indiana introduced a bill providing for a survey of mines, filing of plats, and public advertisements that at set times and places such lands be sold at auction to the highest bidder. California and Colorado protested strenuously, holding that such action would throttle mineral development, that it would shift the burden of the war debt from the East to the West and that the West was furnishing the solid money that held up the arms of the Government, whereupon Congressman Fernando Wood of New York, a great leader of that day, moved that the President be authorized to send an army to expel the miners from California, Colorado and Arizona, "by armed force if necessary to protect the rights of the Government in the mineral lands."

Mr. Wood's plan was to run the miners out, take governmental possession "and work the mines for the benefit of the national treasury." (That was the time for Congress to establish a bureau of mines and mining, with a Cabinet officer, as advocated then, and ever since, by the MINING AND SCIENTIFIC PRESS.) Mr. Wood, who was invincible in peace and invisible in war, found a few supporters in his plan of battle murder and sudden death, but Congressman Washburn of Illinois reminded him that the miners were fighting Indians and digging gold, and were altogether an earnest lot of hardy chaps, and that if Mr. Wood's motion prevailed the Government would probably have a bigger Civil war on its hands than the one in the South.

It happened that at that time the then Territory of Colorado had Jerome B. Chaffee as Congressional delegate. He argued that miners were not trespassers on the public domain, but that their work was essential to the national life and the development of this west half of America, and that so far from being exterminated by the bloodthirsty member from New York, they, as a class, should be allowed some few rights in accordance with their innate privilege to "life, liberty and the pursuit of happiness." He was a miner himself, able to give his fellow Solons a few pointers. Senator Stewart of Nevada and Senator Conness of California were also able to show cause for more peaceable measures.

About that time there was an agitation regarding some Eastern canal rights, and as a great concession when the 1866 law thereon was being enacted, Stewart, Conness and Chaffee succeeded in having tacked on to it a clause giving the Western miner a right to possess and hold a mining location by virtue of annual assessment work. For a long time these regulations were known as the "Chaffee laws." The Government did not further contemplate either sale or operation of the mines. Whether it would have been wiser policy at the time to create a mining code and have the Government share in the production of the property would now be futile to discuss. By 1869 it was manifest that "the lode law of 1866" was insufficient, and in 1870 Congress passed "the placer law," which, as regarding placer mining property, amended and supplemented the law of 1866.

In 1872 a law of the utmost importance to the mining industry was passed. It set the stamp of governmental approval on mining by declaring that all mineral deposits on land belonging to the United States were open to exploration and purchase. The law of 1872 also brought out and confirmed the extra-lateral right, and which, as interpreted by the federal courts, gives the owner of a lode claim the right to follow the vein wherever it goes. Around this point, which includes the "apex" of the lode, have been waged furious wars, wreaking ruin on many and enriching mining lawyers. For over a generation this has gone on. The time has arrived for a federal mining code, which, as distinguished from a lot of loose ideas on a little understood subject, shall be a clear, terse, dignified creation and compilation of national governmental mining requirements commensurate with the importance of the subject regarding which it enacts.

Trans-Pacific Trade.

With the Russo-Japanese war over there is general expectation of increase in demand for all kinds of American machinery. So far as Japan is concerned such expectations should not be too sanguine. The Japanese are as wily in the arts of peace as of war, and their standards of commercial morality are different from those of Aryan stock. They have bought American machinery, but only to copy it wherever possible, and whenever practicable they have merely used their purchase as a model and made no more purchases, faithfully or faithlessly copying what they had bought. Little matters like patents, or trade marks, have not stood in the way. Their commercial value is recognized, but there is usually no recognition of ownership rights therein on the part of many Japanese purchasers. An air compressor or steam boiler, a motor or a band saw, are of primary value to them and exactly reproduced, with the name of the maker, date of patent, as in the original. Such infringement of rights in other countries would invite suit for damages, but the Japanese manufacturer is immune in that regard and boldly appropriates the product of American brains with no acknowledgment of any obligation on his part. Of course such procedure is inimical to expectation of increasing trade. Japan expects to modernize her mills and shops and then compete with America for Oriental business. Her success in that direction will be proportional to her ability to furnish raw material. It would seem that for the next few years there should be good business for American products in Russia and China, where exists tremendous possibilities of demand.

It is manifestly the intent of Japan to make herself as independent of other nations as possible. She possesses considerable coal and copper, but little gold or silver, and less iron, being particularly poor in that basic requirement. For her deficiency in natural resources she will attempt aggrandizement in Corea and China, where late events give her prestige. To China especially will she be likely to look, her ultimate idea being to furnish the engineering there that will utilize that country's mineral resources to the profit of Japan. Japanese engineers are in some particulars as superior to Chinese engineers as they are inferior to American engineers, an inferiority that they hope to overcome. In this regard may be noted as characteristic of Chinese engineering that it is fairly successful along static lines, but a failure in anything that involves motion. Whatever in China has to do with the work of moving men or merchandise is rude and primitive, but their fixed structures evince a higher order of talent. The subtle Japanese hope to absorb the ability of the West to build up a vast Eastern empire and dominate the Pacific.

THAT "you can't run a mine on jawbone" has long had almost the moral force of an axiom, but the narration from Barkerville, B. C., on page 207 goes far to disprove so self-evident a truth in the particular case cited. Contrasting the usual with the occasional, it is to be said that the circumstances certainly were unique, but the statements carry the stamp of truth sufficient to warrant their publication.

American Mining Congress.

There will be a convention of the American Mining Congress at El Paso, Tex., on November 14, 1905, and continuing one week. This organization under different names has led a precarious existence for several years from its inception in Denver, Colo., in 1897. In so far as it aids in any way in the development of the mineral industry of the nation, it is deserving of commendation and support. Its utterances are sound, its declared intent deserves endorsement, and the principles it advocates are of a worthy nature. It has at times been left largely to its own devices, and has not always earned or deserved the dignity and respect that are necessary for the best results from such an organization. Like all similar societies it is just whatever the American miner pleases to make of it. If he go as a delegate to its conclaves; if he contribute with voice and purse to its support; if he take an active interest in its life and welfare, it will flourish. If he neglect it, it will languish. There is a certain field that it or some similar organization could fill with dignity and advantage to all. There is reason for the continuous successful existence of a society having for its sole object the advancement of the mining industry of the country, and so far as it aims toward such high ideal it is worthy of commendation and active personal support. There are several matters affecting the mining industry that might be aided at the coming session of the Mining Congress. Among them are the present need of a cabinet department of mines and mining, with a cabinet officer in charge, as in coordinate departments of the Federal Government. This is so plainly an existing necessity that it requires no argument. Another is the revision of that jumble of statutes known as the United States mining law. Now that ex-United States Senator Stewart of Nevada is relegated to private life, one of the legislative blockades has been removed. While he was in the United States Senate, "senatorial courtesy" enabled him to kill any attempt to simplify or modernize that maze of cryptic mystery—the "federal mining law."

Another matter, though not of such pressing import, is necessary provision by law of method whereby accurate statistics of the production of precious metals shall be secured by the Government. We have an effort in that direction now, but it is largely guesswork. The director of the Mint gives out annual estimates made up as best he can, but they are usually susceptible of successful contradiction. So far as mint receipts go, the statistics are fairly accurate, but a law requiring each transportation company by land or sea receiving bullion to demand from the shipper a certificate of the smelter or assayer, showing the contents thereof in gold, silver and other metals, the consigner, consignee and money value of each metal and that such certificate be immediately deposited in the nearest mint or government assay office to be forwarded to the Philadelphia mint, would appear to be a salutary measure. Supplementary calculation of such items as had been already reported from other smelters and their elimination from the sum total would tend toward final accuracy. The suggested certificates should show in all cases whether the bullion came from the original producer or from a mill or smelter. With such additional data at his command, the director of the Mint could very closely approximate the annual yield.

THE season is almost over for this year in which isolated mining camps are most threatened by fire, but there exists another deadly menace to life in many mining districts in the existence of so many uncovered prospect holes and abandoned shafts. True, there are many State laws and local enactments, regarding those deadly pitfalls and the commonest promptings of safety and humanity almost universally impel prospectors and mine owners to heed such requirements. But carelessness and callousness exist, and scattered throughout the mining region are myriads of man traps. Any one who reads all the local papers every week will note with regret the many fatal accidents resulting from unguarded walking where such deadly holes abound. It is a homely subject, but one of great importance. Often there is an ineffectual or thwarted effort to overcome the danger by covering the hole with poles or planks, but where such covering is stolen for firewood or other use, the condition is worse than before. Holes made in the course of assessment work seem chief among the causes in such fatality. The better way to do is to fill up the abandoned opening. Human life is not so cheap that it can be unnecessarily sacrificed, and the subject is one of sufficient personal import to make every miner who reads this remember that prevention of disaster is not so much a silent precept as an active duty.

Handbook for Metallurgists and Metal Miners.

The mining superintendent of to-day is called upon to meet the same fundamental problems as was his predecessor of yesterday, but in the meantime each of these problems has been complicated by the introduction of new aids and obstacles that were unknown in the past. Within the last few years the development of great forces has been coincident with the development of great mines, and modern mining requires methods and machinery unknown in the past. Great progress has been made, not only in the power, but also in the vehicle for the transportation of material, both underground and on the surface. While the fundamental principles of prospecting, drilling, blasting, timbering and development are the same, yet they have been so amplified by recent experience that ignorance of the new methods becomes a serious handicap to successful progress.

To intelligently cope with all these problems requires a knowledge of the principles and applications not only of mining, but also of mechanical, electrical, civil and chemical engineering. These being understood, an engineer meeting a problem involving their application, looks up how some one else has solved a similar problem, and then modifies such solution to meet the needs of his own problem. Instead of wasting time and thought in devising an original method, he applies the combined experience of others to his own case, modifying it to meet the new conditions. He profits by the mistakes of others and is often saved from making a costly mistake himself.

But this requires an extensive and expensive library of current engineering literature. By necessity the average mining man is a nomad. He has little opportunity or inclination for accumulating and less for transporting such a library. To meet this deficiency various "handbooks" have been devised to give a portable yet comprehensive collection of facts and formulæ; and to-day the civil engineer can ill afford to be without his Trautwine or the mechanical engineer without his Kent.

But it is believed that no single suitable handbook has been written for metal miners and metallurgists. A mining engineer is compelled to get a number of handbooks, each designed for a single class of which he is not a member. Such books necessarily contain much material not pertaining to mining, and they also omit much that is essential to the miner for a proper understanding of the context, but which would be a useless repetition to those familiar with the field. In the aggregate these give an excessive bulk and even then are deficient in many of the most essential subjects.

It seems that a handbook might be written to meet the demand above indicated; a book in which the fundamentals of each engineering branch are lucidly and compactly treated, omitting all the specialized detail except that which is applicable to the field of mining. It would also, perhaps, be well to include an account of metallurgical practice in all its branches, giving a metal miner's and metallurgist's handbook designed for those interested in gold, silver, copper, lead and zinc mining.

To be successful such a book should not be written by one individual, but should be made up of the suggestions of a great number, so as to be of value to all classes of mining men. The work should be under the direction of one having a good knowledge of engineering in general, but understanding that the elementary phases of each should be treated as well as the more advanced. His duty would be to bring the work of specialists within the range of the users of the book, his work to be subsequently revised by the specialists for the correction of errors and omissions.

Every mining man should be willing to help the common cause by suggesting and contributing subjects that in his estimation would be of value to the handbook. This is not written with the idea of merely suggesting a need, but with the intent of filling that need, and it seems that such a work could be profitably preceded by discussions from mining men in these columns.

IN mining and scientific progress few phases are more noticeable than the ease and swiftness of communication as compared with the slow and painful transit of a few years ago. The railway and motor car are doing much for mining development throughout desolate mining regions. Places to which it took days to travel can now be reached in as many hours with a minimum of discomfort. The automobile is greatly in evidence, in the mining world no less than in other fields, and is of prime value. The man who at one period paid 35 cents a mile for a seat in a back-breaking buckboard at a 5-mile-an-hour gait across a Nevada desert finds reason for contrast between past and present in the ease and swiftness of a 20-mile-an-hour automobile jaunt over almost the same region. To associate the prospector with other than the burro, the bacon, beans, flour and frying pan would seem like a severance of indissoluble ties, but it is within reason to believe that to the prospector no less than to the mine owner or mining engineer the automobile will prove of inestimable value. In the mountains everywhere are found the best of natural roads and that the motor will displace slower and more cumbersome means of locomotion is manifest. And this, too, not only for passengers, but for freight service. In this way the automobile will make mining property more valuable in securing cheaper access. This marks a change in accord with the advance in mining and scientific methods. Visitors to mining camps now pass swiftly in palace cars across the way that is ofttimes blazoned with the bones of those who perished on former toilsome journeys through the same region.

THE making of a mine and its development from a prospect to a dividend-paying proposition is usually accompanied by numerous reminiscent remarks, as the stock ascends in value, from those who "could have bought that stock" for as many cents as it now costs dollars per share. "To the victors belong the spoils," and to the man that takes chances belongs the profits that immediately come from the advance in values, and the likelihood of a steady income if the mine shows promise of permanence. This is as applicable to any other form of investment or mode of business as mining. There are as many ups and downs in merchandising or manufacturing as in mining, and, contrary to the usual opinion, while the risks are no greater in mining than in many other business investments, the chances of profit are immeasurably greater.

THE great and growing demand for tin, and its comparative scarcity, makes the Alaska tin ore deposits of exceptional value. The scanty tin yield of Temescal, Cal., and Tinton, S. D., have hitherto been this country's sole contribution to the world's tin supply, which in 1904 was 92,243 tons, being 2512 tons less than the tin consumption of the world for that period. The cassiterite deposits near Cape Prince of Wales, Alaska, are found in an area 10 miles by 25, and are being taken up under the United States placer mining laws. Recent assays are reported to show from 50% to 75% tin. A railroad is projected from Port Clarence, 40 miles south, to the newly discovered tin mines.

THE annual report of the American Smelting & Refining Co. is of material interest from the magnitude of its operations and the position it occupies as to possibilities of profit or loss in connection with the laws of supply and demand. The report shows that for the year ending April 30, 1905, the net income, after deducting $3,500,000 for the 7% dividends to which the preferred stock is entitled, was $4,118,912. The company's present prosperity is partially occasioned by rise in the price of silver and lead. It is also ascribed to increased economy of operations and improved methods. Dividends for one year to the amount of $8,898,811 certainly show the profit and possibilities of such consolidation.

CONCENTRATES.

AIR released from a pressure of 100 pounds will expand four and one-fourth times its volume.

A 10-FOOT head of water would give an approximate pressure of 4⅓ pounds per square inch.

THERE is no metallic zinc mined in Mexico. Zinc is now being shipped from Wallace, Idaho.

IN constant regular work a "horse power" may be considered as equal to the work of eight men.

THE weight of a steel pipe 20 inches in diameter, 150 miles long, ¼ inch thick, would be 41,600,000 pounds.

LEAD went down in price to 2.9 cents per pound in August, 1896. In March, 1877, it was 6⅝ cents per pound.

GREEN lumber will weather season better and quicker if a hole be bored through it lengthwise, and it will also add strength to the stick.

THE green coating on the copper mill plates is a hydrated oxide of copper, and is removable by ammonia, dilute acid or cyanide of potassium.

CARBON DISULPHIDE is usually made by passing the vapor of sulphur over red hot carbon. It boils at 47° C., and when mixed with air the vapor forms an explosive compound.

TELEPHONES are a valuable adjunct in extensive mine operations, being of sufficient economic importance to warrant general use, and any large mine or smelter can find profitable use for them.

SINCE the advent of oil as fuel the coal question of free or duty paid is of secondary importance in California. The coke consumed in California comes from British Columbia, Australia and Antwerp.

IT is permissible to use other mining claims to designate boundaries of a mining claim in locating it, clear reference to natural objects and permanent monuments sufficing to comply with the statute.

IN the casting of brass the pattern should be slightly larger to insure the proper dimensions. The shrinkage allowance on patterns for casting brass is $\frac{3}{16}$ of an inch to the foot in length or diameter of the pattern.

THE apex of a vein is not necessarily a point, but often a line of great length, and any portion of the apex on the course or strike of the vein found within the limits of a claim is a sufficient discovery to entitle the locator to obtain title.

THE latest best unbound work on stamp milling and amalgamation of free gold ores is considered to be the article written for this journal by the late Dana Harmon, and which appeared in the issues of Jan. 17 to Feb. 21, 1903, inclusive.

CRIPPLE CREEK, COLO., is now producing about 75,000 tons of ore per month. Of this about 45,000 tons are chlorinated, 12,000 tons cyanided, 18,000 tons smelted. In the chlorination process the cost averages $3.25 per ton, with a 90% extraction.

WHEN a boiler is to be laid up for some months it should be filled to the safety valve with water at boiling heat, when all air will be expelled from the water, closed to keep out air from the inside and so covered as to also keep out air from the outside.

A PLACER patent includes with it all lodes not known to exist at the date of application therefor; but if a lode was discovered within the placer location limits before such application it could be located, and the placer location to that extent would have to yield to it.

THERE would seem to be some merit in the suggestion that the Siberian black sands be smelted and the gold recovered in metallic iron, but the idea has not been brought to a definite conclusion. Pyritic smelting is practiced in the Altai mountains as elsewhere.

PAHANG, in the Malay peninsula, is reported to contain immense deposits of tin and gold-bearing drift, but which can only be worked profitably by dredging and hydraulic elevators, the details of the work, of course, only determined by careful and thorough investigation.

THERE is no trouble about constructing a wave motor; they are built right along; the trouble is in getting one to develop power. A motor operated by the waves of the sea will deliver power in an intermittent way, but to develop power as a commercial proposition is a different matter.

IN a case of poisoning by phosphorus, sulphate of zinc in 10-grain doses, dissolved in water and given at intervals of ten minutes till vomiting ensues, is the best antidote. A half-teaspoonful dose of old turpentine is also recommended. No oil of any kind should be administered.

STEEL is an alloy, and a very complex one. Alloy steel is that to which other metals have been added to improve its natural properties. Pure iron may be classed among the "rare metals," and not a pound of pure iron has been made under ordinary smelting conditions.

WITH coal at $6 per ton and fuel oil at 80 cents per barrel, delivered, the latter would represent a substantial economy in mine and smelter work. A matteing furnace which would need a ton of coal for every three and three-fourths tons ore should smelt a like quantity with four barrels oil.

CONSIDERABLE of the sulphur used in the eastern United States comes from Sicily at very low freight rates; the cost of transportation usually precludes profitable working of Pacific coast sulphur deposits; makers of sulphuric acid import considerable sulphur from Mexico and Japan.

IT is not unusual to find the upper levels of a mine wetter than the lower levels. Several gold mines along that part of the gold belt of California extending through Amador and Calaveras counties are of that nature, notably the Kennedy of Jackson, Cal. The Lake Superior mines are dry to their lowest levels.

AN atom is the smallest particle of an element which can exist, and it cannot be divided by any means either chemical or mechanical. Every atom of a given element has the same weight, but the atoms of different elements have different weights. The lightest atom is the atom of hydrogen. The heaviest is uranium.

ORDINARILY the Purple-of-Cassius test, of such value in gold chlorination works, is of little avail in cyanide solution, the purple coloration not appearing. If, however, the cyanogen present is got rid of by oxidation or otherwise, the purple color will show with the same delicate clearness as though pure solutions were used.

THE percentage of antimony in hard lead may be very closely estimated by determining the specific gravity. Hard lead consists chiefly of lead and antimony with only small percentages of impurities, and, theoretically, the specific gravity of the alloy should vary according to the proportions of lead and antimony.

AT the United Verde copper mine, Jerome, Arizona, the ore averages 6½% copper. It carries from 15% to 32% sulphur. When heap roasted, such ore is piled 3 feet high on 8 inches of wood, which, being ignited, fires the sulphur on the ore, that burning from five to eight weeks, when the now desulphurized ore goes to the furnaces.

IF the battery screen be inclined outward at the top it will greatly aid the discharge. Strips of ¾ inch wide of $\frac{1}{32}$ inch rubber sheet packing between the tin and wood frame will double the life of the tin screen. If, before using, the tin is burned off before a clear forge fire—just heating to redness—it will anneal and toughen the iron.

BY a miner's inch in Colorado is known that volume of water which is discharged through 1 square inch of an aperture which is 2 inches high and 4 inches long, cut through a plank 1.25 inch thick, the lower edge of aperture being 2 inches above the bottom of the measuring book, and the upper edge 5 inches below the level of the water.

IN South Africa, as elsewhere, the "cheap" miner, that is the low-priced peon, is often found to be the dearest. The Chinese are plodding and patient and in surface or shallow work can be used, but even in such cases a white miner is worth three Chinese, and wherever skilled work in mining is required there can be no comparison.

THERE are two universities within 30 miles of San Francisco, Cal., the University of California, with about 3500 students, and Leland Stanford, Jr., University, with about one-half that number. They both have excellent mining colleges and equally excellent colleges of mechanical engineering. The cost of attendance at either need not exceed $500 per annum.

AT GUANAJUATO, MEX., a 60,000-volt transmission line carries about 3300 electric H. P. 100 miles; one 60,000-volt circuit transmits 13,000 H. P. 147 miles in California, and another transmits 15,000 H. P. 142 miles; two 55,000-volt circuits carry 10,000 H. P. 65 miles, from Canyon Ferry to Butte, Mont. These are but a few isolated instances of long-distance electrical transmission.

RED LEAD is usually tested by oxalic acid and sugar. A much finer way is: Take 2.5 grams red lead, treat with 20 c.c. dilute nitric acid, and shake. The red lead will be converted into the oxide, oxygenated water to be added while shaking. If the red lead be free from barium sulphate, sand or other impurities, a solution almost limpid will be obtained in three or four minutes.

MILL PLATES are silver plated by the electro-plating process. A solution is made of the requisite proportions of cyanide or chloride of silver, cyanide of potassium and water. The copper plate is thoroughly cleaned, immersed in the solution and attached to the negative pole. The silver sheets (anodes) feed the solution, and the silver is deposited on the plates, as the solution, being a conductor of electricity, permits the current to pass through the anodes to the copper plate.

THE amount of air required by a rock drill depends much on the make or design. It is commonly estimated that a 3-inch drill will consume about 15 cubic feet of air per minute, compressed to a pressure of sixty pounds. A 3½-inch drill will use about 20 cubic feet per minute. These figures, which are about a general average, may be used for choosing a compressor which is to operate drills at sea level.

IN the case of Tyson vs. Beill, 70 Pac. Rep., 791, the Supreme Court of Idaho held that where parties enter into a written contract for a lease with option to purchase placer mining claims, the details being given, that such contract cannot be defeated by showing an oral agreement not made subsequent to the signing of the written contract, no fraud or mistake in securing such contract being alleged.

COLORADO quartz mines start in in altitude about where California quartz mines leave off. The bulk of California quartz mines are from 2000 to 5800 feet above sea level. The most of Colorado's quartz mines are above the 8000-foot level, none below 5500. The highest quartz mine in Sierra county, Cal., is the Oakland, 7400 feet above the sea. There are quartz mines in Colorado operated at a height of 13,000 feet.

STATEMENTS made by a party as to the value of goods when selling them where no confidential relations exist between him and the buyer, and the property can be seen and inspected by the latter, are considered as mere seller's statements, and furnish no ground for an action for damages for false representations, as such statements do not relieve the buyer from responsibility of investigating for himself before purchasing.

A BOY of 17 is not too young to enter an engineering school, though he could better grasp the requirements of the course were he a year older. It is not the most brilliant or showy student that always makes the best engineer, the chap who has to "dig" and acquire knowledge slowly often developing into the most trustworthy engineer. In its commercial application engineering is the art of making a dollar earn the most interest.

TIN ore exists in southern California, South Dakota, Texas and Alaska, but for a variety of reasons is not yet being mined in a commercial way. In the Federated Malay States is the greatest present annual production. In Bolivia, South America, a production of 8000 tons and in Australia an annual yield of 3000 tons are reported. The cost of production varies. In Cornwall, England, at the Dolcoath mines, a ton of black tin now costs from $275 to $400.

FIRE CLAY is acid, and when a basic furnace lining is required, dolomite (magnesian limestone) is used. It consists of carbonates of magnesia and lime, from which the carbon dioxide is driven off by calcining. The resulting mixture of magnesia and lime has little coherence, and hence it is coarsely ground and mixed with tar into a plastic material, which is formed into the furnace lining. Heating then cokes the tar and it becomes a cement for the magnesia and lime.

THERE are several welding compounds for steel and iron. One recommended is: Iron filings, 1000 parts; borax, 500; balsam copaiva, 50; sal ammoniac, 75. Mix, heat and pulverize. Another is made thus: Borax, 5 pounds; sal ammoniac, 1 pound; prussiate of potash, ½ pound; resin, ½ pound; alcohol, ½ pint; water, ½ pint; iron filings, ½ pound. Melt in iron pot over gentle fire; allow compound to boil a few minutes until it becomes dry and charred, then pulverize.

SOUTH AFRICAN mining engineers calculate that with a mean temperature of 68° F. at 1000 feet, the rock temperature at a depth of 8000 feet would be 102°, and at 12,000 feet about 122°. In the lower levels of the Comstock, Nevada, a temperature of 170° F. was frequent till ventilating connections were made, when the heat was reduced from 30° to 40°. Detailed discussion has elicited a general belief in the practicability of deep mining in the Transvaal being carried on successfully at a greater depth than 6000 feet.

IT would be impossible to say how much salt there is in a boiler at any given time except by a test with a salometer, or by a boiling test. Sea water boils at atmospheric pressure at 213°, and saturated sea water at 226°. The amount of salt remaining in the boiler depends upon the amount of water that the boiler has evaporated and very slightly on the density of the water. To keep the water in the boiler at a certain density it must be blown down sufficiently to secure that result, the quantity or amount blown down being proportionate to the amount evaporated.

VARIOUS colored cements can be produced by incorporating certain metallic oxides or metallic salts directly with the ground raw materials used in the manufacture of Portland cement, and then burning the resulting mixture in the usual manner. A small quantity of chromic oxide added to the raw cement mixture

will produce a green colored cement; oxide of cobalt will give a blue, varying in intensity according to the quantity of metallic salt added. Oxide of copper will yield a peacock, or blue-green, cement; a small quantity of oxide of iron, oxide of manganese and oxide of cobalt, in almost equal proportions, will produce a black cement.

♣♣♣♣

IN feeding ore to a furnace the fine ore should be thrown against the sides and the coarser in the middle to neutralize the natural tendency of the material in being shoveled up, where the fine will tend to go to the bottom and the center, while the coarse has an equal tendency to go to the top and the sides. Thus, when flung from the shovel, the coarse will go farther than the fine and land beyond it. It may be noted that in a conical heap of ore formed by shovelfuls the coarser particles of ore will tend to roll to the base and the finer will stay near the top.

♣♣♣♣

FIGURES giving in detail the cost of mining and milling free-gold ore have been given repeatedly from special data furnished by experience in Colorado, California, Alaska and South Dakota. In the San Juan district, Colorado, in mining and milling 54,000 tons of ore, among other costs it was determined that the powder used cost 11.8 cents per ton of ore; fuse, 1.87 cent per ton; caps, .081 cent; candles, 4.43 cents; steel, .30 cent; stoping, 1.22 cent; timbering, 47.45 cents; crushing, 8.98 cents; stamping and amalgamating, 27.27 cents; cyanide treatment, including tailings, 70.25 cents.

♣♣♣♣

IN making malleable castings, white cast iron—that is, iron with all the carbon in combination—is melted and cast into the required forms. These castings, which are hard, weak and brittle, are packed in cast iron boxes in the midst of coarsely powdered oxide of iron, usually hematite ore or hammer-scale. These boxes are sealed and exposed to a temperature of full redness in a reverberatory oven for from three to six days. They are then slowly cooled down, and the cast iron is found to be changed to something that is very much like wrought iron in strength, ductility, resilience and softness.

♣♣♣♣

AN excellent way to lay up a cam shaft pulley is to have the boards radiate from the hub and to extend full length from hub to rim. Another way is to lay the boards transverse to the shaft. It will be found, however, that in operation the strain of the belt and the jar tend to make the transverse boards work, until in a short time the rim boards drop or give at every revolution of the pulley. Where the boards radiate from the hub there will be no such drop. In the one case dependence is placed upon the nails and bolts keeping the pulley in place; in the other one has the full strength of the fiber of the wood.

♣♣♣♣

MOLYBDENUM alloys are used for a variety of purposes, combining with steel and other metals for industrial use. Molybdenite, the ore from which molybdenum is produced, is scattered widely throughout this west half of America, in California, Arizona, Nevada, Washington, Utah and elsewhere. To be of much value it must be free from copper and carry 50% or more molybdenum. If it assays 55% it is worth approximately $300 per ton. Metallic molybdenum is worth about $1.70 per pound. Any large steel works can give exact reply as to the likelihood or terms of purchase of the ore. The treatment of the ore cannot be more than a concentration at the mine; the metal is produced at the metallurgical works, where the ore is bought by assay.

♣♣♣♣

THE roasting of sulphides has a three-fold effect. It occasions an alteration of obnoxious compounds into indifferent ones; it removes the sulphur and the ore grains become porous, and the fine gold and silver particles become accessible to solvents; there is also occasioned a certain amount of fritting of the fine ore grains, which allows more rapid leaching afterward. If roasted "dead," the effects will be different. The last-named point would be the same; but, instead of insoluble oxides, there would be a mixture of sulphates and oxides, as well as undecomposed sulphides, and hence a less porous product. If one could transform all sulphides into sulphates at the same time, little could be said against adopting such a method preparatory to cyanidation.

♣♣♣♣

THE mining statutes of the United States require a locator of a mining claim to disclose a vein or lode of ore in place, but do not require that he sink a 10-foot discovery shaft. If he should sink a shaft to any depth required by the local or State or Territorial laws, and then mark his claim and record it according to law, even though he found no ore in place in his discovery shaft, and afterward discovered ore in place in another part of the location, such discovery of ore has been held to cure the defect of not finding ore in place in the discovery shaft, and the claim was adjudged as good and dated to the time of original location. This will not apply to cases where any second locator has obtained conflicting territory by location between the dates of the first location and the discovery of ore in place.

♣♣♣♣

THE assay ton has been repeatedly explained. One pound, avoirdupois, equals 7000 grains; 2000 pounds equals one ton; so that there are 14,000,000 troy grains in one ton, avoirdupois. There are 480 troy grains in one ounce, troy; hence, by dividing 14,000,000 by 480 one gets 29,166 troy ounces in 2000 pounds avoirdupois. Ore is weighed by avoirdupois weight; gold and silver by troy weight. In assay work, by taking as many milligrams of ore as a ton contains ounces, every milligram of gold or silver extracted is equivalent to an ounce to the ton. In one assay ton (A. T.), there are 29,166 milligrams. Hence, by taking one assay ton of ore, one milligram of gold or silver extracted equals one ounce troy to the ton of ore. That is, 2000 pounds is to one assay ton as one ounce troy is to one milligram. Weighing by grains, the assay ton contains 29,166 grains; hence one grain of gold or silver extracted equals one ounce troy to the ton of ore.

♣♣♣♣

THERE are miners' associations in California, Oregon, Idaho and British Columbia, each with substantially the same intent, viz: to advance the general good and protect and foster the industry. The California association of late has been more technical in its tendencies than in former years, and the British Columbia association still debates and resolves. The Oregon and Idaho associations are solely protective in their present tendencies. The Colorado association is composed almost entirely of mine owners and operators. The chief danger in any such association is that it be left to its own devices and be liable to seizure by those who would use it for the furtherance of their own private interests. Whether a Montana miners' association would or would not prosper, "Concentrates" is not prepared to say; but it would seem difficult there, were such an organization perfected, to keep it out of politics.

♣♣♣♣

THE price of the platinum found in the California, Oregon and British Columbia sands varies considerably from the quoted price of pure platinum, just as the price paid for placer gold varies with the fineness or freedom from impurities of what is offered for sale. True, pure gold sells for $20.67 per ounce, and platinum for $20, yet gold will run as low as $13, and platinum as found in these sands as low as $9. The platinum as found nearly always carries iron, iridium, osmium, etc., either in separate grains or usually as a natural alloy, and while the osmium or iridium, if separated, could be sold at high values, yet it requires skilled apparatus to so separate them, and their existence is a detriment instead of an addition to the value in such shape. Native platinum and platinum in place have been apparently authentically reported at various times, but "Concentrates" is not prepared to affirm the known existence of platinum in situ in rock in this country.

♣♣♣♣

THE connection of cause and effect in the case of magnetism and electricity gives rise to the energy produced by and in the electric motor, occasioned by that result of magnetic influence called induction. If a magnet be moved about in the vicinity of a coil of wire whose ends are connected to a means for measuring the passage of an electric current, it will be found that a current of electricity will be generated in the wire of the coil, and that it flows only when the magnet is being moved nearer the coil; and also that as the magnet moves toward the coil, the current flows in one direction through the coil, and as it is being pulled away, the current flows in an opposite direction. By suitably arranging a set of coils and magnets in such a manner that the coils pass in front of the magnets, there can be generated strong currents of electricity. It is by reason of this fact, and primarily on such plan that all dynamos and generators are operated. The ordinary method is to so mount an electro magnet (called the field magnet) that there is a break in the magnetic circuit, across which the lines of magnetism will pass in completing their circuit. In this gap in the magnetic circuit, an armature, consisting of a number of coils of insulated wire mounted on a shaft, is revolved by means of power applied to it. As these coils of insulated wire move through the lines of magnetism, currents of electricity are generated in them which are carried away from the armature for the varied uses of power, light, heat, etc.

♣♣♣♣

THE principal cause of corrosions in boilers is the presence of animal or vegetable oils in the feed water. Most of those oils are composed of glycerine chemically united with acids. When heated they separate into free glycerine and free acid. This decomposition takes place at a temperature of about 2200° F. This is the temperature of steam having a pressure a little above that of the atmosphere, showing that such oils are not safe in even low-pressure boilers. In the case of the liberated acids they attack the boiler plates until they have corroded and carried away an amount of iron equal in weight to the glycerine they have given up. The result of this chemical action between the iron of the boiler and the acids of the oils is a compound that either falls to the quieter parts of the boiler or sticks to the sides of the shell, a sticky black grease that must be removed by mechanical means. Neither common salt nor sulphate of lime are corrosive, but chloride of magnesia is, the hydrochloric acid in the latter when set free attacking the boiler where lime is present, it and the chloride of magnesia also reacting on each other, producing, among other products, carbonic acid. The form of local corrosion known as grooving makes its appearance at the edges of the plates where they come together to form a riveted joint. Grooving is always found on flat boiler heads next to the circumferential seam that joins the heads to the cylindrical shell, and around the points where the through stays are secured to the heads. The cause of grooving is that the boiler material first corrodes to a uniform depth at nearly all points, and then the alternate expansion and contraction causes the protecting layer of corroded iron and boiler scale to crack off at the line of greatest flexure, which is close to the riveted joints and around stays, because the stays through the heads and the double thickness of metal at the joints cause a greater stiffness of the shell at these points, and this results in a concentration of the bending along a line adjacent to the rigid portions. The parts thus uncovered are again attacked, and the above series of operations repeated.

♣♣♣♣

UNDER no circumstances should any one not an expert attempt the manufacture of nitroglycerine, and even if thoroughly understanding the details of its manufacture no move should be made toward combining its constituents unless the operator has all the needed requirements to reduce to the minimum the ever present danger of destruction. In making it the nitric and sulphuric acids are first mixed, the pure colorless glycerine poured in, in a fine stream, the acids stirred while they boil and send out thick red vapors of gas. If the glycerine is poured in too fast, or the water in which the jars set gets too warm, the mixture will blaze with a blowing noise, and if it is not stirred fast the blaze will shoot up 3 or 4 feet. The mixture is kept stirred with a glass rod until the action becomes less intense. Each jar is stirred in turn as glycerine is added, with a good current of cool water running around the jars, until the jars have each had some glycerine. Then that work is begun over again at the first jar, and so kept up till no more action takes place and no more fumes are given off. When all is quiet, and as much glycerine taken as the acids will convert, the nitroglycerine will be in the bottom of the jars, like a milky, heavy, oily-looking fluid. Then the acids are poured off, and it is washed with water, for nitroglycerine is insoluble in water. An old-fashioned wooden churn with a dasher is good for that kind of work. After most of the acid is washed out, and poured out of the jars, the nitroglycerine and acids left can be poured into the churn, water then dipped in, and the churn briskly operated; the wash should be so thorough that litmus paper will show no reaction. One should continue to keep on putting in more water and churning and pouring off, for on the freedom from all acids depends the safety and keeping quality of the nitroglycerine. When the churning is done the stuff is poured into a wooden bucket, and it is ready for use, looking milky, with a little clear water on top. After two or three days the milkiness disappears, and the nitroglycerine looks clear. If it grows yellowish it shows free acid, and should be churned some more with clear water. If it becomes orange colored some lime or soda should be put in the churn. If it begins to look deep orange or cloudy it should be exploded at once, or poured out on the ground where it will not be dangerous. It is a most dangerous proposition from the start, and unless properly handled throughout, disaster is likely to result.

♣♣♣♣

SILVER is easily dissolved by nitric acid and converted into nitrate of silver, but this acid, if pure, does not attack gold. If the nitric acid contain chlorine, however, it will dissolve some of the gold, so that it is always necessary to test it by adding a little solution of nitrate of silver, which will render it milky, from the separation of the insoluble chloride of silver, if any chlorine be present. An alloy, containing two parts of gold to five parts of silver, is most suitable for this process. If it contain a larger proportion of gold than this, the acid will be unable to penetrate to the center of the mass, while if it contain more than three parts of silver to one of gold, the latter will break down to a fine powder, after the silver has been removed, by the action of the acid. With the proportion first named, the silver may be completely dissolved, but the skeleton of gold may be still sufficiently coherent to hold together unless it be violently boiled or roughly handled. Originally the proportion of three to one was employed, and the term quartation, or inquartation, applied to the process, was derived from this fact. The alloy, in a granulated state, is heated with twice its weight of moderately strong nitric acid (sp. gr. 1. 32), in a still made of platinum, glass or earthenware, connected with an apparatus for condensing the vapors of nitric acid which pass off. While the silver is being dissolved, a large quantity of the red gaseous oxides of nitrogen are evolved, resulting from the action of the silver upon the nitric acid, and when these are no longer perceived, the silver is known to be dissolved. The still is then cooled, the solution of nitrate drawn off, and the undissolved gold boiled with a little more nitric acid to extract any remaining silver. It is then washed with water, dried, melted and cast into an ingot. The use of the nitric acid method of parting gold is practically confined to assay laboratories, where it is universally employed. In order to recover the silver from the nitrate, hydrochloric acid is cautiously added, so as to separate the bulk of the silver, as the insoluble chloride, leaving the nitric acid in the solution, which may be used again if care be taken to leave a little nitrate of silver undecomposed in the solution, so as to insure the absence of chlorine. The separated chloride of silver is washed with water moistened with sulphuric acid, and some bars of zinc or iron placed in it when chloride of zinc or iron is formed and dissolved, the silver being left in the finely divided metallic state. The rest of the zinc is taken out, the silver allowed to remain in contact with dilute sulphuric acid to dissolve any particles of zinc, then thoroughly washed with water, dried, melted, and cast into ingots.

Operating a Mine Without Money.

TO THE EDITOR:—Sometimes a miner with more luck than sense strikes it rich; sometimes mining is a straight, unobstructed short cut to fortune, but more frequently sense looms large in mining success. Often the miner meets difficulties sufficient to put his ability and courage to a supreme test. On those few occasions when Fate plucks a commonplace man from the bunch and thrusts him into ephemeral fortune and lasting fame the story of it travels far and becomes a classic. On the opposite hand, a man may accomplish the seemingly impossible in his fight against adverse fortune, and it follows as naturally as his tail follows a dog that the exploit attracts but little more attention than is accorded by those critical incompetents who predicted failure.

These remarks are introductory to the story of a unique example of pluck and fact in mine management. Although the facts related are well known locally, no reference thereto has ever appeared in print—from which it may be surmised that some men are better at doing a thing than bragging about it.

The Slough Creek Gravel Gold Co.'s deep channel placer is in Cariboo district, near Barkerville. The development of this channel was begun by the Slough Creek Mining Co., composed chiefly of Tacoma men. W. F. Sargeant was secretary and money hustler, and John Hopp was manager from 1893 until the present year. The development of a wet channel 287 feet deep requires a lot of money, so it happened that in 1895 the money stringency throughout the United States nullified Mr. Sargeant's every effort to sell stock, so he went to England and began negotiations in "the tight little isle," and finally succeeded in reorganizing the company with a goodly sum in the treasury. It was good work, but it was not quick work—the Englishman doesn't do business that way. He is the best man on earth to back a mining proposition when once you get him in—his word is good, he stays, his feet remain warm. But the wear and tear on a promoter's mind while the Englishman is being separated from his money on a mining deal is nearly hades. It must have been all that to Manager Hopp, who at this time for a period of two years kept the development work going steadily, without fuss, strike, or outward show of trouble, and without a dollar! There was no money to pay his salary, the wages of the miners, grub, tools—anything. I reckon it was the completest, longest stand-off ever put up by an incorporated company. It amounted to $25,000 or $30,000, which, of course, was promptly paid after reorganization. How was it done? I do not know yet, and I was here at the time. Obviously Hopp had entire confidence in himself, Sargeant and the mine, but how he could impart that confidence to all whom those thousands of dollars might concern is certainly a difficult thing to understand, for he is not a brilliant talker, and there is in him no spark of "that genius which your soul leaps to meet." For one thing, he was frank; everyone concerned knew as much about the situation as Hopp could tell him. Another factor was his long-headed foreman, Laurent Muller, now manager of the Willow River Mining Co. This sketch would be incomplete if it failed to mention other men whose loyalty made the work possible: S. A. Rogers and John Peebles, merchants; John Bowron, gold commissioner, and John Stevenson, sheriff and magistrate; miners E. D. Fargo (now accountant for the Cariboo Consolidated), L. D. Muller (now merchant and mine owner at Teller City, Alaska), Robert Fleming (now mine owner at Fairbanks, Alaska), James Shriver, Charles Moulton, Julius Hansen and Ener Enersen. Messrs. Sargeant, Peebles, Moulton, Hansen and Enersen have passed away. Good men and true they were.

I almost forgot to mention Ah Wah, the cook, who was one of the stayers. Imagine the nerve requisite for standing off a Chinaman to the extent of two years' wages!

I trust this sketch will tap other veins of reminiscence in the readers of your valuable journal.

HENRY BOURSIN.

Barkerville, B. C., Sept. 12.

Why Study Mining?

TO THE EDITOR:—Nothing is more difficult to correct in the public mind than its convictions upon education and special classes of training, when once fully committed to an error. Every one knows that for ages past all record, holes in the ground have been dug and mineral in varied forms taken therefrom; and yet, in modern times, certain people have foolishly thought that if men were specially set aside and trained for it, and were to devote their time, thought and energies toward a study of geological conditions, to the improvement in methods of mining, and to the treatment of metalliferous mineral, that mining would, in a productive and business sense, achieve a higher measure of success. As this fallacious notion grew and thrived, they established schools and colleges, instituted courses in practical training, sent their sons to them, spent thousands upon such education and special training, only to find out later on that it was, for them, just so many years and monies wasted.

For other pursuits and professions, of course, a special preparation is essential. No one would attempt to become a doctor, lawyer, banker, merchant, or, in fact, anything else, without a preparatory period of study and a subsequent period in which to acquire practical experience, or a combination of the two. But that it is being very generally accepted at last as wholly unnecessary with reference to mining, among the educated and thinking public, is evidenced by the many mining enterprises entered upon by individuals who have been, probably, fairly successful in other pursuits, and to whom the calling of mining appeals as one of attractive ease and profit and a larger measure of success, when backed by the sound business judgment which has distinguished them in their own chosen pursuit prior to their entry into the mining field. To them it is a matter of tolerant surprise that there should be deemed necessary anything like a training, technical or otherwise, to "simply run tunnels, drifts and crosscuts or sink shafts and winzes." This is the sum total of the necessary work. There are hammers, drills, powder, timber, hoists, etc., and labor. What could be more simple? Method of work and costs as against produced values are matters which must perforce regulate themselves. If the element of cost happens to predominate — well, nothing could alter that. It then, in a manner, becomes "all a gamble," and should never be permitted to rank as a legitimate business, needing special training, study or experience. Any one can mine. That 99 out of 100 enterprises so conducted fail early and miserably is no evidence of the business incapacity in this line of the gentlemen associated with it or any evidence of the desirability of the so-called technical assistance. It simply demonstrates the precarious nature of the mining business in its entirety.

The foolish advocates of professional miners would insist that it is only by reason of study and experience that so many properties of low tonnage value, for many years deemed utterly impracticable, are working profitably to-day; but better informed people know that it is just accident, and that they could have done equally well with such properties had it occurred to them to take it in hand.

And so the tinker, tailor, soldier, sailor, etc., will continue to cheerfully tempt fate in the assurance of their capability and wisdom in the simple matter of mining.

MINER.

Tucson, Arizona.

Ball Nipple Blast Connection.

TO THE EDITOR:—The old method of making blast pipe connections, its delays and annoyances are well known to managing metallurgists. Ever since the Bessemer process was adopted for converting, all connections were made by means of a short stuffing box and a canvas pipe rigidly attached to the converter. This necessitated the removal of all bolts whenever a coupling was made or broken. Time was thus wasted in unbelting from expanded metal.

L. H. Wheeler, superintendent of the F. M. Davis Iron Works Co. of Denver, Colo., has a device in which he uses the air pressure generated for the blast on its way to the converter, to actuate a piston of a greater diameter and area than that of the coupling and its contained surfaces. By this force a short pipe with spherical ends is propelled forward to a junction with a receiving cup or seat in the side of the converter shell, thereby making an airtight and secure contact and connection. One end of this connecting pipe is seated in a piston working in a cylinder formed by a horizontal extension of the blast pipe, the other end being seated as above. By means of a hand lever, the piston and connecting pipe are moved backwards and forward to and from the seats, thus connecting or disconnecting the blast from the converter shell. The ball finish at the ends of the pipe permits of motion in any direction, on the principle of a universal joint, thereby compelling a tight connection to be maintained, although the seats are not in line.

METALLURGIST.

Denver, Colo.

THOROUGH and systematic prospecting is not undertaken nowadays without employment of the diamond drill. Formerly these drills were a monopoly and could not be purchased at all, but had to be leased. Now, however, they are sold outright. Drills and plants can be purchased at prices ranging from $1500 to $5000. A plant once on the ground, it is ordinarily estimated that the cost of drilling averages about 10 cents per foot. The cost of a good hoisting plant and pump is as much as that of a diamond drill. It takes two men to operate a drill and at least that many to sink a shaft. A diamond drill will sink 40 feet a day in hard rock; two men will not average over 2 feet. The diamond drill takes out a core which will show just as well what there is at any depth down to 1500 feet as a shaft, and any number of holes can be drilled rapidly along the vein, so as to cut it at any desired depth down to about 1500 feet. When the diamond drill has demonstrated the fact that the ore is down there and in sufficient body, capital will go after it with a shaft in hot haste.

Summer School of Surveying.*

Written for the MINING AND SCIENTIFIC PRESS by CHARLES DERLETH, JR., C. E †

An examination of the booklet‡ entitled "Summer Session of the University of California" shows that all the University's summer work is not done on the campus at Berkeley. On the coast of the Pacific, 12 miles north of Santa Cruz, where Lyddell creek adds its waters to the ocean, is the Summer School of Surveying, a veritable engineer's camp, Camp California, which, during the session just past, was a village of sixty tents, housing 225 students and a faculty of six instructors, not to mention cooks and other help.

The summer school idea is growing rapidly in the United States. Technical or engineering schools feel the necessity most keenly. During the winter months engineering students have little time for out-of-door work and their practical surveying and mining and machine shop practice must in part, if done at all properly, come in the summer vacations. All our mining students are required to work in a mine at some time during their four years' course, and all mining students devote at least one summer to that work. All students in civil engineering and mining must go to the Summer School of Surveying at least once, while certain students in civil engineering taking the railroad and sanitary engineering courses are required to go two different summers. And so when one looks at the University's summer session prospectus, one finds, as already mentioned, the Summer School of Surveying.

All the large Eastern institutions have summer surveying schools. Some of these are older and more equipped with permanent buildings, but none are larger than Camp California, while the latter has the distinct advantage of lacking all permanent fixtures and being exactly like the roving camp of a railroad party which is locating a long length of track through a wilderness.

During the winter months the students devote themselves to theory and mathematical subjects which form the ground work of the true engineer's training, but at Camp California for two months each year practice is emphasized, always with respect for theory, however, and the young engineer is given a chance to measure his fitness and aptness for his chosen profession. The true engineer is neither the man who devotes all to theory and book learning, nor the so-called practical man who despises mathematics and respects only the rule of thumb, the tape and the hatchet. He is the well rounded scholar who knows to what extent to use his theoretical knowledge so that he may obtain in the quickest time and with the least labor results and designs accurate and strong enough for the particular purposes in hand and for the least expenditure of money. Such a man is not made in four years at college, but only after further years of study and experience; however, during his undergraduate career, the Summer School gives the budding engineer the first good chance to weigh theory and practice and the first principle of instruction at Camp California has always this end in view. While the student weak in theory is discovered at Berkeley, the man lacking in practicality is picked out in the Summer School.

SUMMER CAMP OF 1905.—The 225 students who attended camp this summer represented the freshman, sophomore and junior classes in civil engineering and the freshman and sophomores in mining; 158 of them reported for duty on May 18 and the rest on June 15. Previous experience has developed a complete code of rules for the conduct of the camp and these rules with field instructions, printed in pamphlet form, are distributed to the students before their departure for camp. Students who do not report on the right date or in the right year are fined, and all pay a regular fee of $10 to the University for the privileges of the camp, the use of instruments, and the benefits of instruction, a mere nominal sum which covers an extremely small fraction of the running expenses, which are mainly borne by the University. In the East, students in some institutions pay as much as $35 for similar privileges, which shows in this one way the great boon of our University to the sons of California. Each man pays an additional sum of $20 to the committee of the faculty in charge of finances. This amount covers all living expenses connected with the four weeks' trip and includes railroad fare to and from San Francisco. The University provides the student with a tent. Three to four students occupy a tent together. The camp provides for him a postoffice service and furnishes his meals and equips him with all the main instruments for field surveying. He provides all minor materials, his cot, roughing clothes and bedding, but these are sent in bulk for the class by the University authorities from Berkeley to the camp.

During the past session of May, June and July the camp was under the personal direction of Professor E. N. Prouty, who holds the chair of surveying and

†Associate Professor Structural Engineering, University of California, Berkeley, Cal.

‡This booklet may be obtained by addressing the Recorder of Faculties, University of California, Berkeley, California. A prospectus giving general information regarding the work at the Summer Surveying Camp may be obtained by addressing the Department of Civil Engineering.

railroad engineering at the University. He was assisted by five instructors: Messrs. C. Loring, J. P. Williams, E. A. Gibbs, H. R. Ebright, and Dr. J. C. Blair. These men each represented a special branch of instruction work and further assisted the director, as appointed, in the care and assignment of instruments, the sanitary arrangements, commissary department, meetings and lectures, finances and discipline. Dr. J. C. Blair acted also as camp physician and adviser in sanitary matters, which have been developed to a high and careful standard, a matter of gravest importance in so large a camp. Much credit is due this body of instructors for the efficient instruction at the successful camp season just closed, and the writer of this article, speaking for the home faculty of the College of Civil Engineering, takes great pleasure in making this statement.

THE FIRST DAYS AT CAMP.—Upon arrival at camp in stages from Santa Cruz on May 18, the students and instructors joined hands in the construction of a cook house, a wood house for sheltering instruments, a barn for horses, feed and storage, sanitary buildings and water supply, and in the pitching of nearly sixty army tents. This work is no small job and has proved to be, as already intimated, one of the most valuable experiences for the young men, for it gives them all the conditions of the actual establishment of a large camp on untried ground and all enjoy and profit by it. In Eastern summer schools these opportunities are often wanting, due to the permanent nature of the site and buildings.

FIELD PROBLEMS.—With these matters settled, the work of the school is planned, which has as its final object the making of a complete topographical map of Arroyo de la Laguna Ranch, a property of about 2500 acres, by the freshmen and sophomores; and the running of an imaginary railroad line by the junior class. All of this work is done in a most practical way and with complete organizations of parties so changed in personnel from day to day that every student gets a chance to be everybody from axeman and chainman to transitman and chief engineer. The results of the summer's work are carefully compiled and recorded and used in further studies the following winter at Berkeley.

THE DAY'S WORK.—The discipline is strict and each day's work carefully outlined. At 5:15 o'clock in the morning the rising horn blows, breakfast is served at 5:30 and field work begins at 6 o'clock. Dinner is served at 11:15 and work continued at noon. At 3 o'clock in the afternoon the work-day officially stops because little field work can be done with accuracy during the later afternoon due to the prevailing high winds from the ocean at this season, but so keen are the boys for their work that most of them devote the later hours till 5 and 6 P. M. to the office work of computation and draughting, which is done in their tents. Saturday is a half holiday and Sunday for rest. While the students find their days full and busy there is nevertheless much time left for enjoyment and it is at camp that good fellowship is formed and lasting friendships made. Some of the fondest recollections of an engineer's student days are centered about the rough and democratic life of the camp, and many a student owes many manly qualifications to his camp experiences. At night when the tired parties come tramping into camp there is always food and lots of it to appease the hungry appetites. Three Celestial cooks and an army of student waiters are kept busy satisfying the cavernous appetites of the boys. There is little difference between the three daily meals; hot bread, ham and eggs, beefsteak, milk, potatoes and vegetables, form the menu of nearly every meal. After supper the boys often collect about a camp fire with their songs and stories and all the good natured raillery of college camp life. Saturday afternoon often sees good ball playing. Sunday morning is "washday" in the surf and a mussel bake often fills the evening hours.

Four weeks spent in this way prove of inestimable value to all the men. They get a taste of the application of at least part of their theoretical studies; more than that, they learn to live with their fellows and feel the influence of obeying the chief of party and in turn being the master. But above all it is healthful and invigorating and all return to the city better fit to begin another hard year at Berkeley. The students invariably have a good word for camp and all feel the object of and the end to be attained by the Summer School of Surveying.

PROBLEMS FOR THE FRESHMAN CLASS. — A few words are not amiss as to the detailed procedure of the professional work:

For the freshman and sophomores[2] the object, as already stated, is a complete topographic map of a ranch of about 2500 acres. By parties of three men the angles of a net work of triangles covering the ground are read by repetition and direction methods with engineer's transits; all stations in the triangulation have their elevations determined with respect to a main bench mark on the ocean coast by running lines of levels with engineer's levels, and two base lines, at opposite ends of the ranch which are at the same time sides of the triangulation, are carefully measured with catenary tapes. Each party maps a part of the coast line by plane table surveying and ties it to the main triangulation, and then determines the complete topography of some assigned piece of the ranch property by running a closed azimuth traverse about it with a transit, assisted by plane table and level work for details and contours. Each party computes and reduces the entire triangulation system, starting with one base line and checking to the other, and maps its piece of coast line location and a part of the inland topography.

In all the work methods of checks and balances are used to insure accuracy for the final results, and at all times it is intended that the student shall appreciate the schemes of checks and balances and observe the general unity of the survey of which he is producing a part. Moreover, every student is cautioned to observe what degree of accuracy should be aimed at in each part of the work and to appreciate the degree of accuracy which may, with reasonable care, be obtained with any type of instrument or any given method. The actual completion of a survey of a given piece of land is one thing, but a just appreciation of precision and method and the value of time is another and much more important thing to the engineering student.

By observations of the North Star, Polaris, at elongation, each party determines the azimuth of some line of main triangulation, and the whole network of triangles is tied and checked to a nearby government monument.

Besides this main freshman and sophomore work, each party is given some special problems depending upon the remaining time available and the ability of the individuals. Sextant observations are made upon the sun at noon to determine the latitude of some station of the camp triangulation, and other observations of the same orb when off the meridian to determine the error of the watch and obtain the true time of day.

Special parties also find time to run township lines, to observe the sun for azimuth with solar attachment transits, and some of the mining students are given problems to locate mining claims or to stake out tunnel and mine shaft lines.

PROBLEMS FOR THE JUNIOR CLASS.—There were forty-four men in the junior class who took the railroad field work and they were divided into eleven parties of four men each. These parties were under the immediate charge of the instructors who devoted parts of their time to each of a number of parties, and all parties were under the general supervision of Prof. Prouty.

Each party locates a piece of line about 1 mile in length between two designated points. After a reconnaissance survey with hand level, clinometer, aneroids, pacing and sketch books, and a resulting rough map, the preliminary line is located by transit deflection angles with taping and levels on the center line and side slopes with clinometer. From this field work a preliminary map and profile are made and a paper location platted. A final line is then run from notes prepared from the paper location and adjusted in the field and cross-section notes for cut and fill are made. A computation of earth work in excavation and fill; a final estimate for the complete piece of location and construction; a location map describing the right of way and a location profile showing grades and curves completes the main work.

Special side problems for each party consist in the locating of transition curves and the sketches and studies for bridges, trestles, culverts, embankments etc., as demanded by the special conditions of the various surveys.

Much of this work required heavy grades and sharp curves, due to the extreme roughness of the coast topography, and would be classed as extreme mountain construction, still it is done with all the care and completeness demanded in actual practical problems for important roads to be built to pay dividends. Much of the material gathered by this group of students will be used in their senior studies in the fall at Berkeley in their advanced courses on railroading and construction.

PROBABLE FUTURE DEVELOPMENTS.—1. Permanent Site for the Camp: In the past the camp property has been leased by the University from year to year and has not always been located at Santa Cruz. Every property is not suitable. The site for camp must be readily reached and yet must not be too near a town or city. It must afford a wealth of varying topography for surveying purposes and must be near a large body of water. The Department of Civil Engineering hopes in the immediate future to secure through the Regents of the University a lease for a long term of years of a desirable tract of land so that certain features of the camp may become fixtures. While it is intended to preserve the lack of permanency in the camp life for the reasons already stated, it is desired that monuments, base lines and bench marks become permanent so that the instructors may be better able to check the accuracy of the student's labors, a condition that can only be obtained with a fixed site. Moreover, much labor to the instructors will thereby be saved and more time become available for the real work of instruction.

2. Changes in the Curriculum: Heretofore no surveying instruction was given to the freshman class. With the increased requirements for entrance to the University which have just gone into force, it was made possible, beginning with this year, to require of the freshman what was before done by the sophomores. The freshmen now receive at Berkeley instruction throughout the year and become familiar with all the important branches of plane surveying. The Summer School immediately follows this course of study and tests the student's acquired class-room knowledge. It is hoped that very soon it will be possible to somewhat restrict the scope of the freshman lectures and Summer School, thereby covering less ground, but securing greater thoroughness, and to introduce into the sophomore year an entirely new requirement of surveying lectures to deal with more advanced branches of plane surveying, such as the plane table, solar attachment and solar compass, hydrographic work, mining claims, city surveying, etc., and the elements of railroad field work. These studies in turn are to be followed by a Sophomore Summer School, a new requirement, to complete the field practice of plane surveying. The adding of the elements of railroad surveying to the sophomore schedule will allow further expansion of the junior lectures and the Junior Summer School practice in that important subject.

3. Instruction in Geodesy: At present the University of California gives instruction in those branches of astronomy which are necessary for a proper prosecution of higher surveying. This course is given under the direction of Prof. Leuschner, and so far as the writer's experience goes, is second to none in this country. It is required of the junior and senior students in the College of Civil Engineering who elect the railroad engineering course and deals with the astronomical methods which determine latitude, longitude, time and azimuth. In the senior year the same students receive from Prof. Prouty a course of lectures on higher surveying or geodesy, that branch of surveying which deals with vast areas of the earth's surface and requires that the curvature and size and figure of the earth be taken into account. It is intended to amplify this final course, both by lectures and field work so that in the near future the railroad students may become more familiar with the methods of the United States Coast and Geodetic Survey. Field work, including angle reading with theodolites, base measurements by tapes and compensating bars, barometric hypsometry, precise level work, etc., in combination with the astronomical field work with sextants, transit instruments, etc., now required under Prof. Leuschner, will comprise the fourth and final Summer School.

When this complete program shall have become a working reality, and the time is certainly not far distant, it is safe to state that the civil engineering students of the University of California will have opportunities in the study of plane surveying and geodesy second to those of no institution in the country.

[2] In the future this work will be done regularly only by students who have just completed their freshman studies at Berkeley. Heretofore it was a sophomore requirement.

THE PROSPECTOR.

The samples from Burnt Ranch, Cal., are the following: No. 5, much altered diorite; No. 6 is mostly a variety of soda lime feldspar. It also shows some quartz and a little mica. No. 7 is chiefly feldspar with a little quartz, evidently from a pegmatite vein. No. 8, quartz with considerable iron and copper sulphide; No. 9, vein quartz with small crystals of iron oxide. This rock looks like the quartz often associated with the occurrence of gold pockets in California. No. 10 is chalcocite (copper glance). No. 11 is quartz. No. 12 is a bluish vein quartz, probably gold bearing.

The rocks from Hailey, Idaho, marked "F. C. M.," are as follows: No. 1, phyllite, a metamorphic rock, with some graphite. No. 2 is a much altered greenstone. No. 3 is syenite in which there are also a few quartz blebs. Quartz is not an essential constituent of syenite, but may occur sparingly, as in this rock, without necessitating a change in name. With abundant quartz the rock would be more properly called hornblende granite. No. 4 is pegmatite, a granitic dike rock. The prominent minerals present are pink orthoclase, white quartz, muscovite (white mica) and black tourmaline. It is always a good idea to prospect for tinstone (cassiterite) in pegmatite dikes. No. 5 is gneissic granite. In this may be seen quartz, feldspar, biotite (black mica) and hornblende, all arranged in rudely parallel layers. No. 6 is quartz with considerable copper glance and copper carbonate enough to constitute a fair grade of copper ore. No. 7 is trachyte containing large feldspars, both sanidine and plagioclase. No. 8 is porphyrite, or feldspar porphyry. The greenish color is due to finely disseminated hornblende. A very little quartz can be seen scattered through the rock.

WHEN zincblende is associated with iron sulphide the quality of zinc is sometimes affected by the presence of the iron, but by the employment of modern methods of concentration and reduction of the sulphides the zinc is rendered as free from undesirable elements as that entirely free from the presence of iron sulphide in the ore.

Crushing Machinery for Mines.

Written for the MINING AND SCIENTIFIC PRESS.

There is great variety in the devices employed in crushing ores for subsequent metallurgical treatment. Since the dawn of history the hammer in some form has been employed as a means of reducing rocks and ores to a granular condition of greater or less fineness. This crude and expensive type of crushing machine is exemplified in the various designs of stamp mills, and may be said to reach its greatest capacity, if not its highest efficiency, in that machine known as the steam stamp.

From the stone hammer of the aborigines to the steam-driven crushing machine has been a long step. Centuries have come and gone in the interval between, and yet in some portions of the world the stone hammer, or some modification of it, is still in use to crush rock for the purpose of freeing gold from its rocky matrix and also for other purposes. In Central America the writer has seen a basin hollowed out in a hard, tough rock, the depression having possibly a capacity of a gallon. In this bowl-shaped hole rich gold rock from a neighboring vein was crushed by pounding upon it with a boulder weighing about ten pounds. The boulder was fitted with a forked handle —the branch of a sapling of strong wood. With this rude stamp mill the native pulverized his ore, scooped it from the bowl with his bare hands, unmindful of the sharp-edged cutting fragments, and washed the sand in a horn spoon, making in this way a living with no more capital than his hands and abundant patience, time counting for nothing. The device, simple as it was, answered its purpose, for the reason that the owner of this primitive quartz mill had never heard of a gravity stamp mill, nor of the steam stamp, and looked upon his simple device with satisfaction.

Less than a century ago power derived from an over-shot water wheel, the shaft of which was provided with projections that acted as cams, was employed in raising and dropping a rude hammer-like mass of metal upon ore placed beneath it. By slow degrees the modern stamp mill has been evolved. Even no longer than fifty-five years ago the stamp mill of California consisted largely of wood, the lower ends of the stems only being shod with iron, the stems themselves being square pieces of timber. The iron stamp mill was soon introduced into California practice, however; but the first mills having iron stems and shoes, and iron cams, were far inferior to the modern mills. The principles, however, remain the same—a weight raised by power and allowed to drop upon the ore falling beneath it.

Early in the mining practice of the civilized ages men sought constantly to improve upon the crushing machines, and this effort is still being made. The fact that the stamp was idle the greater part of the time —the period during which it was being lifted and falling again by gravity—has stimulated men to find some device which would be continuous and not intermittent in its operation. The arrastre and the Chile mill are the earliest types of the result of these endeavors. For ages the millman has used a mechanism consisting of a shallow basin in which stood a central upright post, from which projected horizontally one or more cross arms and to these were attached drags of heavy stone. This is the arrastre in its simplest form. Animal power was usually employed in running the arrastre. The stones are dragged around the post in a circle, crushing the ore beneath it by sheer weight and attrition. The stones are disposed from the cross arms in such a manner as to cover as completely as possible the entire surface of the crushing basin in a single revolution of the central post. This simple form of crushing machine has resulted in the introduction of such devices as the Huntington, Griffin and similar rotary mills. Steam, water, electricity, gas engines and other means of power are employed in driving these mills.

Flouring mills have been equipped for ages with grinding or burr stones, and this type of crushing or grinding mill finds its modern representative in such forms of the quartz mill as the Washoe pan, with muller (which really means miller), the Wilcox pan, Knox pan and the various other kinds of grinding pans in which the grinding surface is practically nearly the entire area of the basin.

Although the Kinkead mill is a rotary crushing device, its operation is somewhat different from those above mentioned, as it crushes rather than grinds.

The Chile mill may be rudely described as one or more wheels having a broad face, revolving vertically about a central shaft, crushing the ore in its path by weight of the wheel itself. The original Chile mill was equipped with blocks of hard stone, shaped like a rather flat cylinder, and set on edge. The modern Chile mill is of iron and provided with rings of hard metal—chrome, manganese or chilled steel—to resist wear. Other grinding mills are similarly provided against excessive wear of the grinding parts. As the outgrowth of the Chile mill, have been introduced such devices as the Bryan and similar mills. The various types of this class of mills have been provided with arrangements calculated to increase the crushing capacity of the machine beyond that due to the weight of the rollers only, by the use of springs and other devices.

In addition to these are other types of pulverizing machines of entirely different structure and operation, but perhaps, none the less efficient, and, in some instances, at least, are better suited to the class of work they are required to perform, for it must be understood that every type of crushing mill is not equally well adapted to every class of ore.

One of the simplest forms of crushing machinery is that of cylinders of iron furnished with steel shells running on horizontal shafts and set in pairs, so disposed that rock passing between these cylindrical masses of metal must be crushed as small at least as the space between them. Rolls have been in use for many years, and for certain classes of rock they are perhaps superior to any other crushing device. The early Cornish rolls have been improved upon in many ways by modern machinery manufacturers. The frames have been strengthened and made of better material, the springs controlling the space between the rolls have been placed in many ways, each manufacturer claiming some particular excellence for his devices and attachments. The early rolls were relatively broad for their diameter. More recently rolls have been made narrow and of larger diameter, and calculated to run at high speed. There are a great number of rolls in the market to-day and these represent every variety of shape and size of the rolls—in reference to width of face to diameter of the rolls. Some are set to run at high speed, some at slow speed and others at intermediate speeds. Some are driven by gears, others by belts, and there are numerous other differences of mechanism. Rolls are excellent crushing machines and in their proper place are superior to most other devices for the purpose. As to the relative merits of high and low speed, or intermediate speed rolls, the character of the ore must determine this. Some ores will crush faster than others when the rolls are run at high speed, and vice versa.

There are numerous so-called pulverizers. These are various in design and effect the crushing by means of rolls, impact, grinding or otherwise. There are centrifugal pulverizers, pneumatic pulverizers, grinding pulverizers, pulverizers with rolls and pulverizers in which steel balls or cobbles of hard rock comminute the ore fed into it. Each and every one of these machines has been through the process of evolution—"there is no new thing under the sun."

Beside the numerous types of machines above mentioned, there are others in less common use. These include rocking mills, mills provided with hinged hammers and a few of peculiar and little known design, being mostly "home-made" contrivances of limited capacity and usefulness.

The Ventilation of Mines.

NUMBER VI.

DUST IN MINES AND MILLS.—The researches of the Transvaal Miners' Phthisis Commission led that body to attach very great importance to the dust produced in mining work as the cause of the great mortality from miners' phthisis in the Transvaal, and the more recent report of Dr. Haldane and Messrs. Martin and Thomas on the Health of Cornish Miners takes the same view even more strongly. The latter authors point out the other causes to which the prevalence of miners' phthisis have been attributed, such as an atmosphere more or less vitiated by carbonic acid, sudden changes of temperature, chills from working in wet clothes, absence of sunlight, and so on, are shared in common with metalliferous miners by coal and ironstone miners, who are rather more healthy in respect to this disease than the average population. Then, too, those engaged in occupations which require the worker to breathe an atmosphere laden with stone or metallic dust, such as stone masons, file grinders and potters are affected quite similarly to the metalliferous miners. The common factor is the stone or metallic dust, and there can be little doubt that this is rightly regarded as the main cause of miners' phthisis. The ravages of this disease among miners are so terrible that its prevention by every possible means is one of the most serious problems of public health, and of the highest importance from the standpoints both of humanity and of working efficiency.

The men on rock drills underground are the most affected by miners' phthisis of any class of underground workers, and it is evident to anyone watching them at work that they are in a position which compels them at times to breathe an exceedingly dusty atmosphere. When water can be used in the holes, the dust may be prevented, but in drilling "uppers," and especially in rising, the holes are commonly bored dry, and the crushed rock from the borehole is driven out as sharp sand and dust. The workmen become rapidly covered thickly with dust, and the whole air is full of it, so that the men must breathe it constantly. It is only the excessively fine dust that can reach the workers' lungs, but under such conditions it is evident that some of the dust must get right in. The dust is fine particles of the rock which is being bored through, which is often mainly quartz, and the shape and constitution of the particles are dependent on the physical characteristics and composition of the rock mass. At times, therefore, they may be sharp, splintery, needle-shaped or knife-like, or they may be more rounded or granular. There is a presumption that the former sort of particles would be more likely to cause irritation of the tissues of the lungs than the latter, though there is no very positive proof yet available on this point. Fine particles of steel from the drills are also in the dust, and seem likely to be specially pernicious, as in the allied case of the file grinder's occupation. Besides the dust from rock drilling, there is also a large amount raised after blasting, partly by the concussion stirring up dust that has already settled, and partly from the attrition of fractured rocks thrown out. The air immediately after blasting is often so thick with dust that it is impossible to see a light a yard away from the eyes. The heavier dust soon settles, but the very light particles, which are the dangerous ones, remain suspended for a long time in a dry atmosphere. There is also a good deal of dust produced in dry ground during the operations of shoveling ore to passes and in filling stoped out ground with "mullock." A common cause of dust being raised is the blowing out of air from the "nose" of the rock drilling machine, owing to defective packing, this air preventing the dust from the boreholes from settling. In such cases greater attention to repairs is required. In the mills on the surface there is often a great deal of fine dust generated at the stone breakers, whether of gyratory or jaw crushing type, and in the mills which have dry crushing there is also much dust produced when the stone is ground to fine powder either by stamps, Griffin mills, ball mills or any other similar device. The handling of this dust by elevators and conveyors, its storage in bins and removal therefrom, its treatment in roasting furnaces and removal therefrom are all dusty processes, and unless special care is taken to keep the dust down the whole mill may become full of fine dust. Even when a great deal of care is taken this is very likely to happen, a little dust escaping at all times and a good deal when there is any hitch in the working of the plant, and in consequence dry crushing mills invariably show fine dust lying everywhere, and it is more or less perceptible to the sight in the air of the mill. The dust may be kept down very much, but not entirely. In this State several of the largest mills crush their ore dry and roast it before beginning amalgamation and cyanide treatment, and the question of dust in these mills is therefore important. Under similar circumstances the workers in New Zealand dry crushing mills were, about four years ago, allowed higher wages than in corresponding posts in wet crushing batteries, when the wages were settled by the Arbitration Court, the court considering that the work in dry mills was more unhealthy than in wet treatment. In the dry crushing mills of this State it is usual to have storage bins in which reserves of finely crushed pulp are kept for feeding the roasting furnaces on Sunday and at any other time when the ordinary supply may become suspended. It is sometimes necessary for men to go into these bins to shovel the pulp—a most exceedingly dusty piece of work. Respirators are then generally used. At one mill, however, there was a filthy practice, the men using the respirators indiscriminately, which should be absolutely forbidden; obviously each man should have a thoroughly clean respirator served out to him, which should be used by nobody else till returned to store and again cleansed.

When the mill is a wet crushing one the dust at rock breakers may be overcome by spraying the stone with water as it passes through the breakers, but where the stone has to be crushed dry this is impracticable, as the moisture would have to be removed before the subsequent fine dry grinding would be possible. When the ore is very wet, as it comes from the mine, it is frequently necessary to provide special drying furnaces before it can go to the fine crushers. Sprinkling with water to lay the dust from fine crushing is plainly out of the question too, when the next process is that of roasting the dust, as caking of the material must be carefully avoided. The roasted dust might sometimes be sprinkled after cooling sufficiently, but it is so much more easily carried in conveyors, elevators and shoots when quite dry than when damp that it must generally be kept quite dry. In the dry crushing process, therefore, any method of laying the dust with sprays of water is impracticable. The usual method in vogue here is to close all crushing machines and dust conveyors, and to connect them with dust chambers, into which the dust is drawn by exhaust fans. There being an in-draught at every opening to the machines, the dust is not able to escape into the open air, but is drawn into the flues and dust chambers, or carried through the fans and blown into the chimney stack. Where the method is well carried out it is very successful, and very little dust is seen in the mill, except what has escaped during stoppages of the draught and opening of the machines for cleaning and repairing. There was, however, a great deal of difference in the dry crushing mills seen by us in this respect, some of them being fairly free from dust while others were exceedingly dusty, and required much attention to dust removal.

The devices to prevent dust underground by systems of spraying with water are numerous and

varied, ranging from simple jets of water in the faces to the elaborate systems of mains and standpipes used in some collieries for laying the coal dust, and from vessels of water carried by men, to large spraying tanks running by electric or other power along the mine roadways. It is now recognized that fine coal dust suspended in mine air, if not, as some contend, itself liable to form an explosive mixture, greatly intensifies the violence of explosions of fire damp and that, in a mine where much fine coal dust is lying about, a slight explosion of fire damp may raise such an amount of dust that a very serious explosion may result. Consequently the constant spraying of dry colliery workings is now rendered compulsory by legislation in many countries. It is unnecessary, however, for us to enter into this aspect of the dust question, as our only collieries at present are naturally very damp and coal dust does not rise in them. In the metalliferous mines the question of the humidity caused by spraying has to be taken into account, as some authorities think that the creation of an atmosphere saturated with moisture is likely to be as unhealthy and more uncomfortable than a dusty one.

(TO BE CONTINUED.)

The Murphy Drill.

Herewith is illustrated the newest device in the drill field, the Murphy drill, which its makers say strikes 2000 blows per minute. Another claim to favorable attention is the statement that the exhaust air through the steel keeps the hole clean in front of the bit, also serving the purpose of keeping the bit cool. The makers further say that with it the holes can be put in just as they would be by hand, and shot as often as desired. These drills are stated to be in active use in several large mines in Colorado, Arizona, Nevada and Mexico. They are made by the C. T. Carnahan Manufacturing Co., 1724 Lawrence street, Denver, Colo.

The Murphy Drill.

Charcoal Precipitation From Auro-Cyanide Solutions.

In the district of Victoria, Australia, this method is used, in many cases probably in imitation, rather than with any definite grounds for its superiority over the zinc process.

The methods are identical down to the extractor house, which in a typical plant contains 189 tubs, each 2 feet 4 inches high, 2 feet 1 inch in diameter at the top and 1 foot 9 inches at the bottom. In the center of the bottom of each tub are two small wooden cleats, 4 inches apart, on which rests a glazed drain pipe, 4 inches in diameter, flanged end downwards. Center pipes and tubs are filled with charcoal, coarse for 6 inches from bottom, and medium size to within 6 inches of top of center pipe, with about 3 inches outside, and 5 inches inside the tub of coarse charcoal again. On the top of the charcoal inside the tub and all around the pipe is a wooden lid to keep the charcoal from floating and blocking the outlet pipe.

Another form of tub much used has no center pipe, but there is a false bottom of filter cloth, while on the top of the charcoal is a hinged lid with feed pipe let into it.

The preparation of the charcoal is important, impurities being prejudicial and wasteful. Fine stuff is objectionable, being a bad filtering medium and also passing through into the sumps. Heavy compact charcoal again is not so efficient as that which is light and porous, gold being deposited throughout the whole of light charcoal, so that compact material offers less depositing surface, and is, moreover, more difficult to incinerate. The charcoal is ground and sieved to three sizes—coarse, medium and fine, the latter being discarded. The other sizes are thrown into separate tanks of water, and only that which floats used.

The tubs in above works are arranged in two groups, the first of 141 filters, in twenty-four sets of six each, for strong solution; the second of fifty-four, in eighteen sets of three each, for alkaline wash (0.04% and KCN) and weak solution.

The solution passes down the center pipe of the first tub in each set, coming up on the outside and flowing over the lid through a 1-inch pipe to the next tub of the series, and so on, finally passing away to its own particular sump. The top filter catches most of the gold, and when fairly charged, is removed, each of the remaining five being moved up one step and a newly charged tub being placed in the sixth position. The filter removed is drained of someof its solution and emptied into a large box with a filter bottom, where the rest of the solution is run off into the sump, leaving the auriferous charcoal ready for the furnace room. A tub occupies first position for about three days.

The efficiency of the precipitation is, of course, an important point. The strength of solution does not appear to affect the precipitation at all, the percentage extraction being uniformly high, the solution going out to the sumps in one establishment rarely showing more than three and one-half grains per ton (original value not stated), while 0.04% KCN solutions are successfully precipitated. The gold in the top filters is considerably purer than that caught in the lower ones, and the author suggests that means might be taken to keep the contents of the top filters separate. Frequent tests show steaady diminution in the value of the gold, taking the place downwards through a set, till the bottom tub is nearly pure silver.

The exact action of thecharcoal has never, as far as the writer knows, been experimentally demonstrated, but he thinks it may be due to the hydrogen and hydro-carbons remaining in the charcoal, the result being the formation of hydrocyanic acid and free gold. This KCN represents a certain amount of loss of active agent.

From the filter house the auriferous charcoal is conveyed to the furnace room, where it is incinerated in four reverberatory furnaces, each 10 feet long. The ash is sieved through a 900-mesh trommel, and the coarser residues returned to the furnaces. The fine stuff or "ash," containing about 80% gold, is then smelted.

The author points out what appears to him to be the following advantages:

1. A high-class bullion is produced—one well-known mine receives £4 per ounce for cyanide gold.
2. Percentage extraction is high regardless of strength of solution.
3. In spite of the large amount of auriferous charcoal to be handled the "waste" is easily got rid of by burning, and the ash is easily smelted without the necessity of treating with strong acids or careful oxidizing roasts (with some unavoidable loss).

One great disadvantage is the greater chances of loss through the immense bulk of stuff to be handled, and the higher cost of the operation itself. The cost of charcoal precipitation (with charcoal at 9d per forty pounds) works out at 4.29d per ounce of gold, or 0.545d. per ton of stuff. Zinc precipitation (with zinc at 4½d per pound) would cost 2.25d per ounce of gold, or 0.275d per ton of stuff. Labor works out at 0.763d per ton for the charcoal, and 0.382d per ton for zinc. To recover the gold from the "ash" at these works costs 1s per ounce, bullion 900 fine, exclusive of labor, as against about 2d for zinc slimes, which would probably average not more than 800 fine. There remains the question of increased outlay for plant and buildings, but these are not very serious. Considering the same works, the 198 tubs cost £247 10s; zinc boxes would require but a small portion of this.

FROM three to eight days is the time considered by cyaniders as requisite for maximum extraction of gold, dependent on existing local conditions. The general idea is to use a weak solution and give plenty of time.

Treatment of Copper Ores by the Electric Furnace.*

By M. VATTIER.

We are not dealing here with a philosopher's stone which would, as by magic, transform any copper ore into a mass of pure metallic copper, or which would overthrow and supersede the well-known reactions of the old metallurgy of copper. Nor do we pretend to have discovered a process which suppresses all the cost of production, and permits of reaping imaginary millions from any kind of ore under any conditions. We abandon the monopoly of these pretentions to the fancy prospectuses which circulate in certain financial centers, and which cause such diappointment to the credulous investors, and we approach the subject in a more scientific and industrial spirit, and especially with the intention of facilitating, within the limits of our powers, the labor of the indefatigable workers who strive to further improve these processes, and whose efforts deserve praise and reward.

You all know that, generally speaking, in the metallurgy of copper by dry processes, either in reverberatory or water-jacketed furnaces, the copper ores are first of all converted by the help of coke or coal into copper matte containing 40% to 50% of the metal; these mattes are then submitted to a roasting, followed by a remelting, either by special treatment in converters or in Thofern and Saint-Seine reaction furnaces, which transforms them into copper bars; these are then refined by electrolytic processes, which produce the pure copper and effect the separation of the gold and silver.

At present our object is solely to suppress the consumption of fuel (coke, coal or charcoal) used to smelt the ore for the production of the matte, and to replace these calories of the black coal by electric heat derived from the "white coal;" that is from hydraulic forces. Then we proceed to the refining of this matte by the processes now in use in metallurgy (converters, furnaces, etc.), and all we ask from electricity is to lend us its aid to produce the heat, whenever it can be done with advantage, by the introduction of the electrodes.

In a word, the endeavor is to develop a process which could be established in regions favorably situated as regards water powers, and where coal is costly; it is the difference between the cost of the black coal and the white coal, which shall constitute the main profit derived from the adoption of these new processes. It is bearing these conditions in mind that we made the series of experiments of which I shall now give you a brief account.

ORE.—Our experiments were conducted on two different kinds of ore.

First—Copper ore from the Volcan mine, Chili, belonging to Gregorio Denoso. The copper contents was approximately 7%, present as copper pyrites. This ore contains from 8% to 9% of sulphur, and the gangue comprises silicates, silica, a little carbonate of lime, but mainly micaceous copper oxide.

Second—Low-grade copper ore from the mining regions in the vicinity of Santiago, Chili, mixed with a small proportion of manganese and lime.

The composition of the charge of the furnace was as follows:

	Per Cent.
Carbonic acid	4.310
Silica	23.700
Alumina	4
Lime	7.300
Magnesia	0.33
Sulphur	4.125
Iron	28.500
Manganese	7.640
Phosphorus	0.046
Copper	5.100
Arsenic	trace

These ores were crushed partly into large pieces and partly to dust. The crucible was filled with a hand shovel, indiscriminately, of the coarse or dust, and without experiencing the inconveniences which usually accompany the presence of "fines" in the water-jacketed furnaces. All the charges were very carefully weighed and sampled, and an exact record of the various phases of the experiments was kept. Rather large blocks, at first refractory, were soon dissolved and incorporated in the molten charge, after undergoing a pronounced gyratory movement.

FURNACES.—The main furnace, for the first fusion or breaking up of the molecules by the application of heat, is a chamber or crucible built of refractory bricks, and having the following dimensions: Length, 1.800 meter; width, 0.90 meter; height, 0.90 meter. Below this chamber we have a forehearth, in which can be effected the sharp separation of the matte from the slag; the dimensions of this forehearth are as follows: Length, 1.20 meter; width, 0.60 meter; height, 0.60 meter.

At the bottom of the upper chamber there are some openings which can be tamped at will by means of fire clay, for the purpose of tapping the contents into the lower forehearth. In the upper chamber two carbon electrodes, with a square section of 0.30 meter on the side, and a length of 1.70 meter, are introduced, and their height may be so regulated as to either be immersed in the bath or just clear its surface.

Into the forehearth penetrate two carbon elec-

*From the French.

trodes of 0.25 meter on the sides, which are used to reheat the bath. Openings are left at different levels of the forehearth, and which are opened by means of steel rods driven in by blows of a hammer, for the purpose of tapping either the slag into small sand trenches, or the matte into steel ingot moulds, which are handled by an overhead crane. Voltmeters and ammeters permit of observing the intensity of the current. Alternating current was used. A special contrivance allows of easily and independently raising and lowering each of the electrodes.

PROCEDURE OF OPERATIONS.—The two large electrodes are lowered into the upper chamber, and the circuit is established by the introduction of pieces of carbon and of matte placed at the bottom of the crucible, and the temperature is gradually raised. The ore is elevated by a hoist to an upper platform, and is charged into the furnace around the electrodes, which are raised in proportion as the burden increases. Fusion begins to take place in a very short time, and when the crucible is full of molten or semi-molten material a taphole, situated some 0.10 meter from the bottom, is unplugged by means of a steel rod. The molten mass, more or less pasty (quite fluid after a short time), flows into the forehearth, where the reactions are completed, and where the separation of the liquefied materials is effected by means of the reheating electrodes.

When this forehearth is nearly full the slag is evacuated through one of the upper openings, and as soon as the quantity of underlying matte is judged to be sufficient, it is tapped off by one of the lower openings. It is thus a process of successive tappings, both from the upper and the lower crucibles.

DATA OF THE METHOD.—The furnace has a smelting capacity of twenty-five tons of ore per twenty-four hours, which it converts into matte. The current used for the experiments was of 4750 amperes; 119 volts; cos $\phi = 0.9$, which corresponds to 500 kilowatts, or 680 H. P. Therefore, to treat one hundred tons of ore per twenty-four hours will require from the dynamos 2833 H. P., in round numbers 3000 H. P. of 76 kg/m.

PRODUCTS OBTAINED.—Mattes of the following composition were obtained:

	Per Cent.
Silica	0.800
Alumina	0.500
Iron	24.300
Manganese	1.400
Sulphur	22.960
Phosphorus	0.005
Copper	47.900

and slag of the following composition:

	Per Cent.
Silica (SiO_2)	27.200
Alumina	5.200
Lime	9.900
Magnesia	0.390
Iron	32.500
Manganese	8.230
Sulphur	0.570
Phosphorus	0.062
Copper	0.100

The slags at both the beginning and the end of the operation usually contain a slightly higher proportion of copper.

The slag has high contents of iron and silica and could be used to manufacture ferro-silicon. For this purpose it should be poured directly into a special crucible, submitted to the high temperature of the electric furnace as soon as possible, in order to take advantage of the heat it possesses when it is tapped out of the crucible.

If the slag should be high in manganese, it could be manufactured into ferro-manganese and spiegels.

REMARKS.—For good results it is advisable to use a voltage sufficient to cause the arc or electric current to pass from one electrode to the other, by regulating their height to just clear the surface of the bath, in order to avoid as much as possible their coming in contact with the bath. Carbon at such high temperatures has a tendency to reduce the iron oxide into metallic iron, which gives rise to the following inconveniences:

First—A more rapid wear of the electrodes.

Second—Loss of electric energy.

Third—Decrease of the copper contents of the matte.

By the use of Acheson's graphite electrodes these inconveniences would be greatly diminished.

The economic and other advantages of this new electro-metallurgical process are at present quite evident, without having to defer judgment until further improvements are introduced. The problem may be said to have been solved by the Livet experiments.

COMPARISON BETWEEN THE OLD PROCESSES OF COPPER METALLURGY AND THOSE OF ELECTRO-METALLURGY.—Let us consider the case of a copper mine situated in South America, in Chili, for instance, and at some distance from the coast, in the foothills of the Cordillera; such a mine is the Volcan, the ore from which was submitted to the experiments of electric smelting; under these conditions coke costs at least 100 francs, and owing to the slope and other local conditions, a powerful and constant hydraulic power can be developed economically. We shall take for purposes of comparison the figures relating to one ton of copper ingots, extracted from the Volcan ore, which has a copper content of 7%; this is a comparatively high tenor, higher than the average mines worked on a large scale.

For the production of a ton of copper we shall have to treat some sixteen tons of ore; we shall neglect the figures, which would be the same for both cases as regards mining of the ore and subsequent treatments, and we shall restrict ourselves to the comparative elements of the two methods.

First—In the present water-jacketed furnace, the production of the matte, containing one ton of metallic copper, shall require 3200 kilograms of coke, at 100 francs per ton, that is to say, an expenditure for fuel of 320 francs.

Second—In electric furnaces the smelting of sixteen tons of ore will require an energy of 1.25 kilowatt-year, at a cost, in the region in question, of 30 francs per kilowatt-year, representing a cost of $1.25 \times 30 = 37.50$ francs, say 38 francs.

The wear of electrodes, as shown by our experiments, amounted to 75 kilograms per ton of copper in matte, so that we may calculate an actual cost of 45 francs for this item; this would be greatly reduced by the adoption of electrodes such as above mentioned, and more especially of graphite electrodes.

In short, the electro-metallurgical process for the smelting of sixteen tons of ore would entail a cost of:

$$38 + 45 = 83 \text{ francs},$$

and the economy effected, over the water-jacketed furnace, in the fundamental element of heat energy is, therefore:

$$320 - 83 = 237 \text{ francs, or more than £9.}$$

The additional important advantages derived from the use of electric furnaces are the following:

First—Suppression of the blowing engines, which are essential in connection with water-jacketed furnaces.

Second—The possibility of operating on much more refractory ore than with the water-jacketed furnace.

Third—Suppression of the manufacture of briquettes or of an agglomeration of the fines and dust.

Fourth—Notable decrease of the cost of labor.

Fifth—Elimination of the danger of scaffolding of the charge in the interior of the furnace; this accident is comparatively frequent and costly in the water-jacketed apparatus; moreover, choking up and obstruction of the hearth is likewise avoided.

Let us now consider the case of low-grade ore, say 4%; the production of one ton of metallic copper in matte shall require:

First—In water-jacketed furnace, an additional expenditure of coke amounting to

$$\frac{100}{1000} \times (5000 - 3200) = 180 \text{ francs.}$$

Second—In the electric furnace, instead of 1.25 kilowatt-year, we shall need two, which entails an additional cost of

$$30 \times (2 \text{ kwt.-yr.} - 1.25 \text{ kwt.-yr.}) = 22.50 \text{ francs.}$$

Which represents an additional saving of 157.50 francs, which figure is comparatively important for a low-grade ore.

It is, of course, impossible to arrive at a general average figure representing the savings effected by the adoption of the electric furnace; this depends on the grade of the ore and also on the local conditions; yet, in the case of the ores produced from the South American mines, remote from the coast and in proximity of powerful and constant waterfalls, the economy effected would certainly not be less than £10.

Placer Mining in Alaska.*

NUMBER VI.

In drifting operations on a bench of Anvil creek, Seward peninsula, a main long adit was run 4 by 6 feet 6 inches in the clear, at a cost of $4 a foot, untimbered, for the entire width of the ground in a direction transverse to that of the creek. This was 500 feet in length and was 10 feet below the surface of the schist bedrock. The average depth of the ground was 20 feet, being 2 feet of muck, 11 feet of wash gravel containing almost no gold, and 7 feet of pay dirt, the last consisting of 5 feet of pay gravel and 2 feet of bedrock, which contained the best pay. This was the thickness drifted. The adit served as a drain for the workings. The ground was only partially frozen, and it is likely, as has been found in parts of the Alaska interior, that the constant draining of the ground assisted in a gradual thawing of the frozen parts. From the end of this main adit a long tunnel (600 feet) was run for the length of the ground which was to be drifted, at a level of 8 feet above that of the adit floor. This was timbered with 6 by 6-inch posts, 8 by 8-inch caps, sets with 4-foot centers, lagged with 2 by 6-inch plank, top and sides. From this long drift cross drifts were run in a direction parallel to that of the main adit, at intervals of 100 feet, and with lengths of 40 feet on each side of the main longitudinal drift. The ground was then breasted, carrying a 40-foot face toward the adit. The Hidden Treasure system of timbering, using false sets, was employed. Track was laid both in the main adit and in the upper workings, and cars of 21 cubic feet capacity were employed in tramming, four in the main adit and from fifteen to twenty in the upper workings. The stopes never exceeded 20 feet in back and forward dimensions. The timbers used were 8 by 8-inch posts, 7 feet long, 10 by 10-inch caps, 11 feet long, 5-foot centers, all ways, between posts. Boards were laid down to shovel on. The ground was so heavy that it was found impossible to save the timbers, but the track was all recovered. In extracting 21,000 cubic yards timbering cost $14,000, with lumber at $50 per thousand.

The gravel was trammed to the surface and distributed on a long dump 40 feet on each side of a previously constructed 24-inch sluice 500 feet long. As usual, planks were laid on top of the sluice, and when spring opened the gravel was caved and horse scraped into the sluice. In distributing the gravel on the dump three men and a horse scraper had to be employed most of the time in keeping the snow off, on account of especially heavy snowfalls when the work was being done. When completed, the dump measured 700 by 80 by 20 feet, approximately. The drifting work consumed nearly eleven months, and the sluicing about two months, being delayed on account of frost in the gravel.

Labor employed averaged forty-five men in two shifts of ten hours, at winter wages of $2.50 a day and board. A shift in the drifting operations consisted of ten men shoveling into cars, averaging 8 cubic yards to the man, and three to four trammers took care of the dirt shoveled. In sluicing, ten men and two horse scrapers were used to a shift. The product of the operations was $160,000, and the cost, including preliminary prospecting, was 59% of the output. The work was done in 1901–2, and the opinion was given by the operator that the cost could be decreased 20% under present conditions.

In drifting operations on high benches lying between Anvil and Dexter creeks, near Nome, the gravel must be hoisted through shafts. It is said that powder is efficient in extracting the frozen ground. This is contrary to experience in the Alaska interior, and is doubtless due to the fact that the gravel is not nearly so solidly frozen. In fact, it is said that the powder is used for only a portion of the time. From the main shaft, which must be in some cases 230 feet deep to reach the second pay streak, a drift is run the length of the pay ground. From this transverse drifts are run at alternate intervals of 50 feet in each side of the main drift. Some operators sink the shaft on the side rather than in the center of the ancient channel, as by this method the shaft is less likely to "squeeze." The shafts are 3 by 6 feet, timbered with 2 by 12-inch plank laid up on the sides, with 2 by 4-inch timbers set vertically on the corners inside.

The face can be carried from 50 to 100 feet in length in the winter, as the constant slight freezing renders the gravel less heavy. In summer, on the other hand, the ground must be worked in small blocks. With the methods of timbering in use, 6 by 6 to 10 by 10-inch sawed posts are put in, on base block, and with a short 4 by 12-inch plank caps, posts having 3-foot centers in all directions. A space of three sets in width is generally carried before the ground is allowed to cave. When the ground is ready to cave a bulkhead is nailed to the second set, the timbers are pulled with ropes from the third, and the caved ground is caught by the bulkhead. The breast is then carried forward as before. No lagging is used except in the shaft and the main runway. In summer work the area of bedrock exposed in one stope rarely exceeds 10 square feet.

In sluicing the dumps from winter operations on the high Anvil benches, the expedient is adopted of building small dams of sod and erecting snow fences behind them to catch snowdrifts, so that sluicing water may be afforded in the spring from the melting snow. The remarkable phenomenon of deep-lying pay streaks on the Anvil benches has been considered by A. J. Collier in his geological account of the Nome district.

On Eagle creek, in the Birch Creek district, an interesting drifting operation was seen. It is especially difficult to work the creek claims by drifting on account of the partially thawed character of the gravel. A bedrock drain was run in winter at one side of and parallel with the paystreak, and low enough to drain all the ground which it was proposed to work. The drain was covered and lagged with poles and thus rendered permanent. A shaft was then sunk at the lower end of the ground, 4 by 8 feet in dimensions and 20 feet deep. This was timbered only for the upper 14 feet, and was sunk in three days by two men. A tunnel was then run upstream the length of the ground, wide enough to admit 8-foot caps. Posts were 5 feet long, all timber being 9 inches square. Sets had 4½-foot centers, and the tunnel was lagged overhead with 2½-inch flattened poles. A set of timbers delivered cost $4, there being thirty-four caps to a cord of wood. Lateral drifts 8 feet wide were driven at intervals of 8 feet, 4½ feet in thickness of gravel being taken. The gravel was wheeled to the shaft and windlassed to the surface, about 25 cubic yards being raised in ten hours. The lamentable lack of any tramming arrangement for transporting the gravel to a distance resulted occasionally in the caving in of the ground from the added weight of the dump. The gravel so laboriously raised was thus lost. Some idea of the difficulties of operating on Eagle creek may be seen from the following figures: Wood was $10 a cord, not excessively high; lumber, $180 a thou-

*Bulletin 263 U. S. Geological Survey.

sand; freight packing rates from Circle, on the Yukon, 25 cents a pound in summer and 8 cents in winter. Considering the remoteness of the district, the work carried on was remarkably good and systematic.

THAWING.—One who has never visited the interior of Alaska finds it difficult to conceive the formidable condition of solidly and perpetually frozen alluvium which is there encountered by the placer miner. The quantity of water in the form of ice which occurs in the frozen gravel averages about 25%; while in the overlying fine, black silt which forms the overburden the quantity of ice varies from 50% to 75%. Whatever may be the physical composition of the material, it forms a mass as solid and as difficult to penetrate as solid stone, and can be disintegrated only by exposure to the sun's rays or by the long-continued application of some form of energy artificially applied.

In any open-cut operations the dense blanket of moss, from 12 to 18 inches in thickness, which covers the frozen ground, must be broken into and turned over either by adzes or plows before the action of sun and water can take any effect on the underlying muck. As has been said, this effect is remarkably rapid when the water is allowed to run over the exposed black and icy mass.

A curious condition exists in the treeless area of Seward Peninsula. Wherever a growth of stunted willows occurs, the ground beneath is found to be thawed, and wherever the willows are replaced by moss the ground is frozen solid. The rule is not without exceptions, but has been found to have rather general application. The distribution of the willows and moss covered patches in the creek bottoms and along the low valleys appears to be entirely irregular.

Drifting operations in the creek deposits of the Klondike, Birch Creek, Forty-mile and Fairbanks districts of the interior are nearly always carried on in solidly and perpetually frozen ground. A necessary accompaniment of the work is the thawing of the ground by artificial means. G. W. Pichard has thoroughly investigated for this report the possibilities of using any form of the electric furnace for thawing the frozen gravel and has reached the conclusion that electric thawing is impracticable. Artificial power, through the agency of the steam point, is only in rare cases applied in open cut work. The Klondike district afforded a few examples of this application of power, notably in connection with dredging operations on Bonanza creek, the steam shovel operations on Bear creek and in two open cuts on Upper Dominion and Hunker creeks. It is difficult to determine the efficiency in open work, as, naturally, a portion of the thawing is done by the sun. From the data collected, however, it does not appear to be any greater than its underground efficiency, which will be presently discussed.

The method of thawing gravel underground by wood fires is expensive, and, unless the conditions are very exceptional, is not used in those districts where transportation facilities permit the bringing in of boilers.

According to experience on Deadwood creek, Birch Creek district, the efficiency of a wood fire in creek ground was as follows: A fire taking three-fifths cord of wood (at $12 a cord) is built against the face of the bank. The pile of wood will be 18 inches wide, 2 feet high and 25 feet long. Stones are laid up over the pile and a space is left to light the fire. The fire is lighted at 5 P. M. and left to burn until 8 A. M. the next day. The stones, which quickly get hot, are regarded as most efficient in thawing.

(TO BE CONTINUED.)

How World's Weight Is Calculated.

When Newton set himself to find the law by which an apple falls to the earth and the planets revolve at varying speed along their orbits, he constructed a formula which would explain these phenomena. He laid it down as a law that the force with which the earth attracts the apple or the apple the earth, or the planets one another, is equal to the mass of the one multiplied by the mass of the other, and divided by the square of the distance between them—the whole multiplied by a constant called G. G is the Newtonian constant of gravitation. It is of all the constants the most important to physical science; it is a constant for the more accurate determination of which Prof. Boys has been willing to spend five years of arduous and minute observation. Mitchell first devised an instrument by which it would be possible to obtain, by actual observation, the attraction which two bodies have for one another.

Cavendish improved upon Mitchell's observations, Cornu carried it on. Professor Boys has carried it two decimal places further. If Professor Boys were to hang a couple of 50-pound lead balls by two fibers he would find it as impossible to measure the inclination of the two fibers to one another as to weigh a sunbeam. But there is a possible way of measuring the attraction, and Professor Boys has made it more practical by the employment of quartz fibers to suspend some of the balls he uses. He uses four balls—two gold balls ¾ inch in diameter, weighing forty or fifty grains, and two lead balls, 4½ inches in diameter and weighing each sixteen pounds.

Suppose these four balls in their first position suspended in one plane. The two little gold balls are suspended by quartz fibers on either side of an oblong mirror, to which they are attached. If any force were to pull one gold ball a little way forward, and at the same time to pull the other little gold ball a way back, it is obvious that a twist, an oscillation, would be imparted to the tiny mirror. So delicately is this mirror, with its gold balls, hung on its tube, that a force equal to the hundred-millionth part of a grain will set it swinging. With this degree of sensitiveness attained, one begins to get near some means of measuring influences upon it. The influence we can measure is that of the two lead balls. We imagined them to be, in the first instance, in the same perpendicular plane as the little gold balls. Suppose we move them contemporaneously and coequally, so that one lead ball moves in front of one gold ball and the other lead ball moves, exactly in the same way, behind the other gold ball. If the hanging of the mirror and its gold balls is delicate enough, it is obvious then that the force exerted by the attraction between the gold balls and the lead balls will give the mirror to which the gold balls are attached a little twist and will set it oscillating. The instrument is delicate enough.

Seated 80 feet away the observer can time it. He therefore can measure the force which the lead balls and the gold balls exert upon one another; he can measure the distance which the balls are apart; he can measure the balls. Therefore, knowing the force, the masses and the distance between them, he can determine the great constant G, and, knowing G, he can determine the specific gravity of the earth; he can find its weight. Prof. Boys, after years of experiment, has found the specific gravity of the earth to be 5527. Before this time we were content to regard it as 5.5. He has taken five years or more to establish these other two decimals. Taking this as a basis, the weight of the world may be figured as 5,882,000,000,000,000,000,000 tons.

The instrument which contains the system of gold and lead balls is put in the corner of an underground crypt in Oxford. There is too much tremor of the earth in London. It is boxed up in a thick octagonal wooden box. It is separated from the observer by a series of felt curtains. He sits 80 feet away and examines its movements by means of a telescope through slits in the felt curtains and in the wooden box, and in the metal tubes holding the gold ball system.

The mirror reflects a 9-foot scale with 5000 divisions placed behind the observer's head. To avoid creating currents of air, Professor Boys has the scale illuminated only by a little traveling lamp. To avoid tremors of earth, he works at dead of night, for a train switching a mile away will move that tiny mirror; and once an earthquake in Transylvania, on the other side of Europe, was marked by it. As to the measurements, the distance of the lead balls from one another is calculated by micrometer and microscope to the three hundredth part of an inch, the distance of the gold ball quartz fibers in the ten thousandth part of an inch, and a force equal to the millionth of a grain would be sufficient to send the reflection of the mirror right off the scale.

Ice Making and Refrigerating Machinery.

A severe test of pumping machinery was made by the Ice & Cold Machine Co. at the ice making and refrigerating plant, Louisiana Purchase Exposition, St. Louis, Mo., during the entire period of the Fair.

Fig. 1.—Cameron Boiler Feed Pumps.

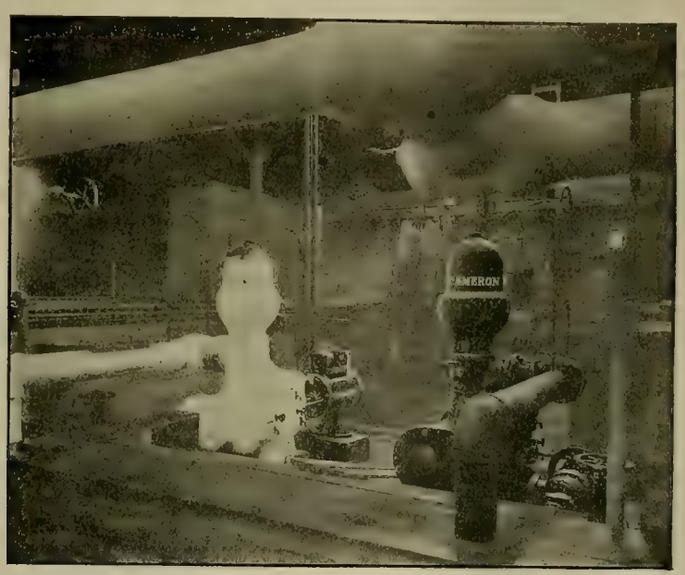

Fig. 2.—Cameron Special Brine Circulating Pumps.

Fig. 1 shows two Cameron boiler feed pumps, 8x6x13, in the boiler house, and used for supplying two water tube boilers of 750 H. P. Fig. 2 shows two 10 x 9 x 18 Cameron special brine circulating pumps, of the light service pattern, having long bodies and composition linings, also in operation at the plant, and were used alternately in the refrigerating pipe line, which was claimed to be the longest continuous line in operation using brine as a refrigerating agent. These pumps were in constant use day and night from May 14, 1904, to the close of the Exposition, December 3, for the 500-ton refrigerating machine, with the two ice tanks capable of making 120 tons of ice daily, and cold storage space of 100,000 cubic feet. Brine at a temperature of 10° F. was put into the pipe line and pumped through the various and numerous refrigerator boxes, containing 60,000 cubic feet, at the "German Tyrolean Alps," 7000 feet from the plant, the brine traveling through the pipe 14,000 feet after leaving the pumps before returning to the brine coolers. The manufacturers state that these pumps successfully withstood the constant rack and strain to which they were subjected. P. D. C. Ball of the Ice & Cold Machine Co. states that the service was entirely satisfactory.

The pipe line was used by other parties for refrigerating between the above mentioned points, the connections and arrangement being such that no difficulty was experienced in getting proper circulation, and without interfering with other boxes on the line.

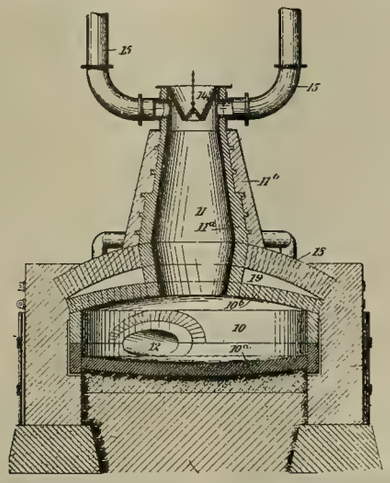
The pumps presented a unique and picturesque appearance, owing to their being covered with a layer of frost. One old mining engineer's wife remarked: "Those pumps look like statuary, and unlike the old station pump at the mine shaft, which we have seen in service nigh on to twenty years."

Mining and Metallurgical Patents.

PATENTS ISSUED SEPTEMBER 5, 1905.

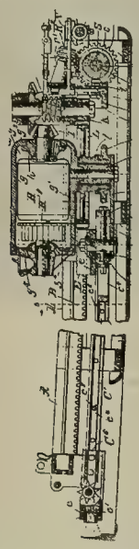
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

SMELTING FURNACE.—No. 798,312; H. L. Wrinkle and N. Wrinkle, Keeler, Cal.



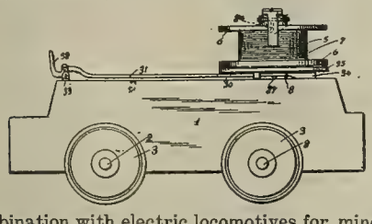
Smelting furnace having circular crucible, permanent outer top wall for crucible, inner top wall below outer wall and spaced therefrom to form circular chamber, stack sustained by outer top wall and passing through both top walls, radial partition in circular chamber, air blast pipe passing into chamber at one side of partition, and air blast pipe passing from chamber at other side of partition and leading into crucible.

MINING MACHINE.—No. 798,108; E. R. Merrill, Columbus, Ohio.



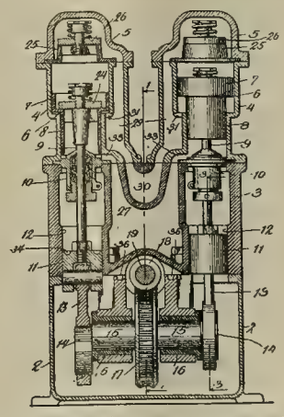
In mining machine, combination of bed, carriage, cutting apparatus on carriage and arranged to be thrust thereby directly into coal, two-part feed mechanism, of which one part is secured to bed, and other is supported by carriage, electric motor having armature shaft arranged longitudinally of machine, bevel wheel at rear end armature shaft, vertical shaft behind motor, bevel wheel thereon above bevel wheel on armature shaft, worm gear on vertical shaft, gearing interposed between vertical shaft and carriage feed mechanism and means connecting vertical shaft to cutting apparatus.

REEL FOR MINE LOCOMOTIVES.—No. 798,389; H. Booker, California, Pa.



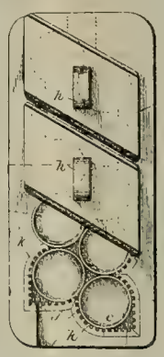
Combination with electric locomotives for mines, of revoluble shaft operated by locomotive, disk carried by shaft, drum loosely mounted upon disk, cable carried by drum, means to establish electric connection between locomotive and cable and means to hold drum in stationary position.

PUMP OR COMPRESSOR.—No. 798,506; M. W. Hall, Brooklyn, N. Y.



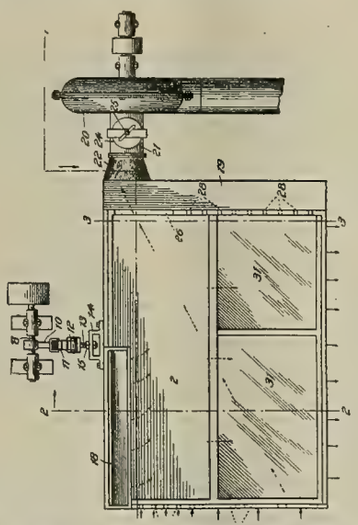
In pump or compressor, combination with cylinder having differential bores, of differential piston fitted to bores, piston having passage therethrough, valve carried by piston controlling passage, discharge valve controlling discharge from forward end of larger cylinder bore, cylinder provided with inlet passage leading to rear end of smaller bore thereof at rear of smaller head of differential piston, and passage through wall of cylinder separating differential bores, connecting rear end of larger cylinder bore at rear of larger piston head, with discharge.

ASSAY FURNACE.—No. 798,950; W. W. Case, Denver, Colo.



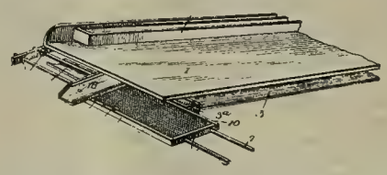
In assay furnace, combination of wall thereof having flame inlet near bottom and near one end thereof, series of crucibles located in furnace, crucibles nearest fuel inlet partly surrounded by wall of furnace to protect them from too rapid heating, wall provided with exit for products of combustion located in proximity to rear top thereof, series of projectors, or heaters, arranged within wall of furnace and around crucibles located at or near rear end to heat up latter rapidly enough to keep pace with heating of crucibles located nearer fuel inlet.

DRY ORE CONCENTRATING TABLE.—No. 798,843; A. Tetrault and E. C. Pohle, Boulder, Colo.



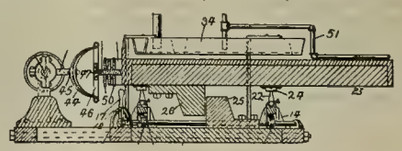
In dry concentrator, smooth surfaced table, cover therefor forming top chamber, leaving openings across three edges of table, closure for fourth edge thereof, casing forming exhaust chamber extending across openings at one end of table, pipe connected to one end of exhaust chamber, means to draw air therefrom connected to pipe, open ended pipe rising from latter, valve controlling open ended pipe for regulating volume and force of air currents, feed hopper opening into table chamber at closed edge, means for causing reciprocating bumping movements to table.

SEPARATING AND SIZING ATTACHMENT FOR CONCENTRATORS.—No. 798,632; J. H. Smith, Creede, Colo.



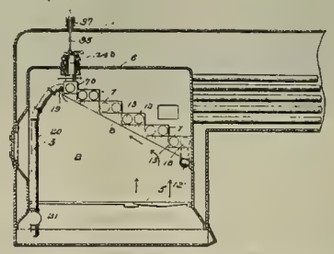
Attachment for concentrating tables, comprising angular supporting brackets, pair of guide rods carried by brackets, rectangular screen frame having end bars apertured for reception of guide rods and series of openings in side bars, middlings trough supported by frame at one end, trough retaining devices engaging openings, screen mounted on frame at one side of middlings trough, and values trough secured to frame and extending beyond opposite side of middlings trough.

SLIME CONCENTRATING TABLE.—No. 798,842; A. Tetrault and E. C. Pohle, Denver, Colo.



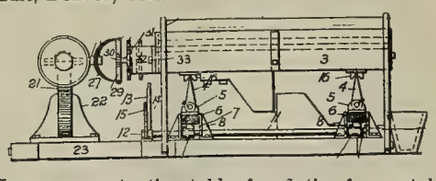
In concentrating table, foundation frame, means thereon for supporting table in operative relation to frame consisting of bracket guide rising from each corner of frame, pair of beams loosely fitted in pair of guides, means arranged beneath beams at one side of frame for simultaneously and vertically adjusting ends of beams, means carried by other ends of beams for independently adjusting each vertically, pair of rocker arms mounted on upper side of each beam, adapted to swing at right angles to length of beams, in combination with table mounted on rocker arms, abutment carried by table, abutment carried by frame, means for reciprocating table, means for adjusting table toward and from its driving crank shaft to vary its stroke consisting of crank shaft, pitman rod bow spring, links connecting spring, head connecting links having screw stem, loop bracket secured to and projecting from table, and nuts engaging screw stem and bracket.

STEAM BOILER FURNACE.—No. 798,684; J. J. Le Duc, Mankato, Minn.



Combination with firebox having water space surrounding, opposite stepped brackets provided upon inner walls of firebox progressing upwardly and forwardly from back with steps at one side staggered with respect to steps at opposite side of firebox, headers supported upon steps of brackets, each header provided with inlet and outlet, water tubes extending between corresponding headers at opposite sides of firebox, each tube inclined upwardly from outlet of one header to inlet of next above header at opposite side of firebox, inlet connection between lowermost header at one side of firebox and water space at back of firebox, and outlet connection between upper portion of device and water space at top of firebox.

ORE CONCENTRATING TABLE.—No. 799,021; A. Tetrault, Denver, Colo.



In ore concentrating table, foundation frame, table having V-shaped bearings on under side, pairs of pointed rock arms engaging grooves of bearings, pair of beams supporting rock arms, means for adjusting beams at feed end of table, guide brackets within which both ends of beams are loosely placed, means on beams engaging brackets to prevent rock arms from sliding out of table bearings, and means for reciprocating table.

MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

ALASKA.

Henry Bratnober has discovered copper at the headwaters of the Nabesna, White and Tanana rivers. —— It is stated that John Rosene and associates will build the Northwestern & Copper River Railroad to the Nabesna copper district within three years. Rosene's first section of 35 miles from Valdez is now being built.

ARIZONA.

Cochise County.

It seems certain that the wagon road to the Bacoachic district in Sonora from the Nacozari railroad will be started. It will open up a rich mining district tributary to Douglas, but which is severely hampered by lack of transportation. The road will open up a large number of camps in the Arizpe district.

Near Charleston, south of Fairbank, is a new discovery by J. Lorrien, the values being principally in vanadinite of lead, although there are other ores of lead in the veins. It is claimed that this ore can be concentrated and the concentrates of the vanadinite of lead saved.

Regarding tungsten a recent report of the United States Geological Survey says that there were quite extensive operations conducted on the tungsten deposits in Cochise county. These deposits occur 13 miles from Benson and 6 miles north of Dragoon, in the Little Dragoon mountains. This area has been pretty thoroughly prospected for tungsten ores by means of open cuts, pits, shallow shafts, etc. These prospect cuts and pits have been made on a long ridge, in the gulches of which placer and float tungsten minerals have been found, principally hubnerite, in aplite veinlets and crystalline quartz that occupy fissures in the main body of granite constituting the country rock, also as hubnerite and wolframite, which are due to the alteration of the incasing wall rock and flank the vein itself. Scheelite has occasionally been found in small seams or streaks with the hubnerite. The deposits near the surface have been more or less decomposed. The belt containing these veins is the ridge at the head of Texas ridge and Sheep canyon. There has been considerable work done on this ridge by running in crosscuts and tunnels to intercept these veins, but many of the lower tunnels which were run in sufficient distances to have intercepted the vein if it existed found no trace of it at these lower depths, with the exception of the Bluebird vein, which seems to be more continuous than the others. This vein occurs at the contact of granite and intrusive diorite. It has a strike of north 50° east and dips 55° to 60° toward the east and is on the hanging wall side of the diorite dike. The tungsten minerals in these veins are very apt to occur in bunches and also in streaks, so that a large proportion of the vein contains little or no tungsten minerals. In some instances where the vein is a number of feet in width, the tungsten minerals have been concentrated in seams 5 to 6 inches in width; then again, rich bunches of hubnerite ore, from a few pounds to four or five tons of nearly pure ore, averaging from 50% to 60% tungstic acid, have been obtained. The supply of tungsten ore from this locality has been obtained from the veins, and also from the placer deposits in the gulches below the veins, and it is probable that by far the larger part has been obtained from these placer deposits. One estimate made of the production of this locality has been over 500 tons of tungsten ore, of which not over fifty tons have been obtained from the veins themselves, the balance being the result of mining in the placers. The percentage of tungsten in these ores varies from 50% to 78%, and usually it can be concentrated so that the ore will yield an average of 68% of tungstic acid (WO_3).

It is reported that the Empire Copper & Gold M. Co. intend sinking a three-compartment shaft 700 feet to develop their claims, near Johnson. J. L. Brooks is manager.——The Cons. M. Co. has sunk 260 feet on the Republic mine and 275 feet on the Mammoth mine, both near Johnson. The Republic is shipping ore to El Paso. S. J. Entriken is manager.——A double-compartment shaft is being sunk on the Black Prince, near Johnson, under the direction of Robt. Mackey.——It is reported that the smelter of the Southwestern S. & R. Co., at Benson, is to be completed under the direction of Manager Doane Merrill. The works are to be of 350 tons capacity, with one 250-ton water-jacket blast furnace and one 100-ton reverberatory furnace. The product will be a 60% matte.

Work has commenced this week on the Cochise Dev. Co.'s property, near Bisbee. The old shaft will be widened to a two-compartment. Orders have been placed for a double-hoisting engine, boilers, compressors and air drills. C. L. Jones is managing director and Robert Ludwig mine foreman.——At Gleason the Copper Belle Co. is putting in additional machinery. A new blower for the smelter is being put in place. The miners have been blocking out ore to be run through the smelter when it starts up again.

Gila County.

The August production of the Old Dominion Copper Co. at Globe was 2,242,000 pounds of blister copper as compared with 2,080,000 pounds in July. An accident to one of the blowing engines interfered with production for seven days. The company's new plant has been completed at a cost of $1,500,000 and paid for. Three furnaces are in blast at the Old Dominion smelter and the concentrator is running continuously.——The Pinal Copper Co. of Globe, of which C. W. Slack is superintendent, has been reorganized in St. Louis and will hereafter be known as the Arizona Banner Copper Co.—— The Arizona Commercial Copper Co. recently stopped shipping ore from the Copper Hill mine to the Old Dominion smelter, as there would be a saving to the company of $5 to $6 per ton if the ore was first concentrated. The Old Dominion Co. was charging the Arizona Commercial Co. $3 per ton working charge, but had made an additional charge of $4 per ton on account of the Copper Hill ore being highly siliceous. They may make an arrangement with the Old Dominion Co. for concentrating the ores, whereby the largest part of the silica will be eliminated, in which case shipments will be resumed, otherwise they will build their own mill. It is stated that a diamond drill is being put in.

Graham County.

Rich silver ore has been found at the bottom of the 200-foot shaft of the Commerce mine, 14 miles from Duncan. Arthur Murphy is superintendent. —— Considerable second-class ore is being shipped from the Standard copper mines north of Clifton. ——Good milling sulphide ore has been struck after driving 200 feet in a tunnel on the Copper Plate mines, near Metcalf. Ambrose Burke has charge.

Mohave County.

W. G. Kelly, of Winslow, Arizona, is directing work on a mine near the Ark, 16 miles north of Kingman. Work will be continued until water is struck.

The Vivian M. Co. is building a mill near the shaft, to the east of the Mohave & Milltown railroad at Vivian. The shaft is down 200 feet. A supply of water for all purposes is said to have been found in the mine.

Santa Cruz County.

The recent sale of the Grubstake gold and silver mines of the Blanco district, near Nogales, to the Grubstake M. & M. Co. recalls the early discovery of the property when it was considered a rich silver mine while now it is considered almost entirely for its gold, running $12 per ton, with large bodies of ore. Many years ago these mines were located for silver, when that metal was high. Out of one shallow shaft and crosscut the original locators, Holden & Hewitt, took $17,000. To-day the mine is to be worked as a gold mine.

Yavapai County.

At the Senator mine, 12 miles south of Prescott, Superintendent A. J. Pickerell has the tunnel in 2500 feet.——In the same district the Gold Copper Co. is running a development tunnel from Crook canyon under the superintendency of T. Marmont. —— At the Mt. Union mine, south of Prescott, the shaft is down 530 feet, with drifts from the 400 to the 500-foot levels. The ore is crushed and concentrated at the mine. E. E. Greenwood is manager and L. Greenwood superintendent.——At Walker, the Metals M. Co., under the management of G. W. Middleton, is developing the Sheldon and Monroe properties. A car line extends to the Sheldon, with a branch to the Monroe. At present the cars are hauled by animals, but the company has contracted with the Arizona Smelting Co. for electric power sufficient to supply the mines, car line, and a new mill of 250 tons capacity.

At the Jeanette–Arizona mine, near Hillside, the shaft has been sunk 440 feet under the direction of Superintendent Carbaugh.

CALIFORNIA.

Amador County.

The Oneida mine, near Jackson, is to be prospected to greater depth. A winze is to be sunk from the 2400 level to a depth of 600 feet. The grade of rock at present being worked is low.——At the Zeila mine, near Jackson, thirty of the forty stamps will be run by electricity, the other ten will be run by water power. This utilization of water for part of the mill is necessary to supply sufficient water to carry off the tailings.

El Dorado County.

Richard Reed and Clifford Cheek will put in an arrastra on the Silva mine at Georgetown.——The Gopher-Boulder mill near Kelsey has been started up on a test run. C. S. Hersey of Georgetown is millman.

The River Hill mine, near Placerville, has reached a depth of 1300 feet, 1000 feet in the main shaft and 300 feet in the winze.——At the Nigger Flat mine, near Placerville, they are boring for the channel and splendid progress is reported.

Humboldt County.

A 3-stamp mill is being put in at the Fern Leaf mine at Orleans Bar, 65 miles by trail from Arcata. F. S. Elder is superintendent. The lighter machinery is being packed by mules to the mine, while the heavier sections are to be hauled by wagon to Hoopa, and then carried up the Klamath river by boats to within 8 miles of the mine, whence they will be taken in by sleds.

Los Angeles County.

(Special Correspondence).—The Lowell & California M. Co., F. C. Fenner manager and J. L. Witney superintendent, have started their new 10-stamp mill at Bighorn on ore from the No. 6 tunnel, averaging four tons to the head.

Bighorn, Sept. 16.

Mono County.

(Special Correspondence).—The metallurgical treatment of ore at the mines of the Standard Con. Co. at Bodie has been materially changed within the past eight months, and is now one of the most modern in California, including crushing in cyanide solution, further crushing in tube mill and final treatment by the Moore process. The ore is crushed to 30 mesh in the 20-stamp mill. Crushing is done in cyanide solution, using two pounds of cyanide per ton of ore. Plate and battery amalgamation save 60% of the values, which run from $18 to $20 per ton. The plates have an inclination of 2½ inches to the foot. After concentration by vanners the pulp is elevated to the tube mill, where it is first classified by spitzkasten and the coarse material fed to the tube mill, together with the sands and slimes from the vanners, which are fed dry. Irregular pebbles from Mono lake have been used, but, being irregular, they slide and will not roll, causing greater wear on the liners and requiring more power. Hereafter Iceland flints, now being shipped, are to be used. The tube mill crushes to 150 to 200 mesh. The coarse material from the mill is separated by spitzkasten and recrushed. The pulp then passes to settlers and the settlings, 25% to 30% solid, are treated by the Moore process. This makes an extraction of 85% from the slimes and mill tailings, as compared with 70% extraction obtained before regrinding was tried. The concentrates from the vanners are ground fine with strong cyanide solution in pans and also treated by the Moore process, giving an extraction of 95%. In the Moore plant two "baskets" or units of filters are used, consisting of a series of parallel plates 4 inches apart, each plate being about 20 feet long and 4 feet high, consisting of a light framework covered with canvas. In the original plant a suction pipe passed through the top at the center to within ½ inch of the bottom; two blowpipes also entered at the top. The whole series was hung from a crane, which raised and lowered the basket and carried it from one compartment of the tank to another. The filter is lowered in the slimes compartment and the vacuum pump started, the slimes being agitated to prevent settling. The suction is continued until a coating of slimes is formed on all parts of the filtering surface to a depth of from ⅛ to 1 inch. During this time the pump is continuously discharging the clear gold solution. The crane then carries the basket to the weak solution and to the wash water, the vacuum preventing the cakes from dropping off during the transfer. To discharge the cakes, a blast of air is turned into a pipe connected with the blowing pipes of each plate and the vacuum pump is stopped, the air dislodging the slime cakes, which drop into cars below. The filtrate from the baskets passes to the zinc boxes and thence to the sump, whence the solution is pumped to the mill. The Moore process is giving satisfaction. Theodore J. Hoover is superintendent of the mine and mill and W. P. Hamilton is foreman of the plant.

Bodie, Sept. 18.

Nevada County.

It is stated that the Gaston M. Co. at Gaston intends running a tunnel from Poorman's creek, several thousand feet below the present workings. The new tunnel would be over 5000 feet in length in order to reach the ledge, 3000 feet below the surface. The present tunnel is 2000 feet long.

The Prescott Hill shaft, near Grass Valley, has a depth of 650 feet, and it is the intention of the Sultana Co., which owns the mine, to put it down 500 feet farther.

Shasta County.

Suit has been filed in the Circuit Court of northern California by Joseph A. Coram against the Balaklala Con. C. Co. of Nevada; the Western Exploration Co. of Utah; F. H. Buhl of Sharon, Pa.; G. H. Baird of Chicago; Willard F. Snyder of Salt Lake City, Utah; the executors of the estate of Peter L. Kimberly, and the White Knob C. Co. of Maine, to prevent the sale of the Balaklala Co.'s property to the White Knob C. Co., which previously operated in the Hailey district in Idaho. The complaint states that on April 3, 1905, F. H. Buhl, representing a majority of the directors of the Western Exploration Co., which at that time owned the entire capital stock of the Balaklala C. Co., with the knoweledge and consent of the other directors, Peter L. Kimberly and Willard F. Snyder, who owned and controlled a majority of the stock of the Western Exploration Co., authorized J. A. Coram to sell the Balaklala property for $750,000 cash and $1,000,000 worth of stock in the consolidated company of which the Balaklala was to form one of the constituent parts. Pursuant to the authority granted to him, J. A. Coram accomplished the sale of the property on May 3, but on July 3 the Western Exploration Co. sold the property to the White Knob C. Co. Coram prays that the sale to the White Knob C. Co. be set aside and the Western Exploration Co. be compelled to pay damages in the case. The complaint further shows that Mr. Coram, in his endeavor to keep his agreement with his principals, tried to purchase a controlling interest in the White Knob C. Co. The agreement between Mr. Buhl and Mr. Coram, under which the latter sold the property, is also exhibited.

The rates which the Mammoth Copper Co. at Kennet has established for the treatment of siliceous ores are as follows: Ore from $3 to $15 a ton assay value will be smelted free, and 75% of the value returned to the shipper. On ore between $15 and $25 in assay value, 77½% of the value will be returned to the shipper and there is no smelting charge. On ore from $25 to $50 a ton, 90% of the assay value will be returned and a charge of $2.50 a ton will be made for smelting. On ore from $50 to $75 a ton, 95% will be returned and a charge of $5 a ton will be made for smelting; on that assaying from $75 to $100 a ton 95% will be returned and a smelting charge of $7 a ton will be made. On ore from $100 to $200 a ton, 95% will be returned and a smelting charge of $10 added. In addition to the above percentages of gold, 90% of all silver values will be returned on ores assaying above five ounces to the ton. No return will be made on less values. Only siliceous ores as high as 90% in silica will be subject to a smelting charge; gold will be paid for at the rate of $20 per ounce and silver at current New York quotations. No lots of less than ten tons will be received at the smelter.

Sierra County.

It is stated that A. J. Pinkstone, superintendent of the Sierra Buttes mine at Sierra City, will develop the Comet quartz mine in Jim Crow canyon, 5 miles from Downieville.

Siskiyou County.

The Eliza mine on Humbug, near Yreka, is being developed under the superintendence of C. A. Patterson. The machinery for a new quartz mill and cyanide plant is on the ground.——The Deadwood placer mine, near Yreka, has been sold to a syndicate of Chinamen at San Francisco, headed by U. S. Interpreter Mun.

Tuolumne County.

It is reported that a pumping plant, 100-ton gravel mill and excavating machinery are to be put in at the Montezuma gravel mine, near Columbia. W. T. Beveridge is interested. —— Leasers are working the New York tunnel on Table mountain, near Columbia. The lower channel has not been reached.——A drain tunnel has been run 1000 feet to unwater the Cincinnati mine,

near Columbia. The shaft was abandoned because of the water.——The Richards' claim on Table mountain is to be unwatered by the Muir tunnel.——The Truckenmiller Con. M. Co. are making a raise to tap the gravel channel, having run the tunnel 670 feet. Sluices and gravel bins are being put in to work the gravel. H. Knott is superintendent.

The Clio shaft, near Jacksonville, is down 400 feet.——At the Mustang mine, near Confidence, twenty-two men are at work. A 5-stamp mill has been put up and a short mill run made. J. M. McMahon is manager.——At the New Calico at Stent the shaft is down 220 feet and the ground to that depth has been explored and ore blocked out. At present they are crosscutting at the 200 and drifting north and south on the west ledge. The expense for fuel, for hoist, pump station, drills, etc., runs $5.60 per twenty-four hours.

COLORADO.

(Special Correspondence).—Although W. S. Stratton of Cripple Creek fame has been dead for a number of years, every few months some one files a suit against his estate, claiming that at some time or other during the life of the deceased he had furnished him a sack of tobacco to prospect on, or some other similar charge. The latest suit filed is by a party named Meredith, who claims to be a mining engineer, and who further claims, according to reports, that there is coming to him from the Stratton estate $10,000 commission from a mining deal that never went through and $50,000 for the depreciation of the stock on account of the deal not having been consummated.——According to the U. S. Mint report for 1904 recently sent out, Colorado seems to be in the front rank as a gold-producing State. This year should see a much larger production than during 1904, as the districts affected by the strike are about to their normal condition and others are forging ahead.——During the past few years there is a tendency to put in electric power for operating various machinery employed on a mine. In a number of instances a company has secured control of water rights on certain streams for power purposes and has harnessed same up with electrical machinery, strung wires for a distance of 20 or 30 miles over mountain ranges and are supplying power to the mines for 10% to 40% less than the mines can produce their own power by shipping in coal. When this was first talked of, some said it could not be done on account of the climatic conditions they had to contend with in a mountainous country. It has been done and a number of such projects are now under way throughout the State. Wherever tried it has been a success and a source of revenue, not only to the company selling the power, but to the purchaser of the power. There seems to be considerable agitation for electric roads to the mines. One of the late ones to come into prominence is at Telluride, where a franchise has been granted to a company who intends to build an electric road into Marshall and Savage basins, and will not only carry passengers, but ore and supplies as well. According to report, they have agreed to reimburse the county of San Miguel for the amount of money expended on the county road into these basins. The greatest difficulty to be encountered will be through the winter months on account of heavy snow and slides, but this, like the difficulties with the electric lines for power purposes, will undoubtedly be overcome. If such an undertaking proves successful, it will be the means of others throughout the San Juan and other sections of Colorado.

Denver, Sept. 18.

According to J. H. Pratt in a recent report of the United States Geological Survey, the tungsten deposits of Colorado are located in Boulder, Gilpin, Lake, Ouray and San Juan counties, with the more important deposits in the first-named county. The deposits in Boulder county are in the vicinity of Nederland and Sugar Loaf, ann these localities produced by far the largest proportion of the tungsten output of 1904. According to the reports received from the producers in this county, the ore concentrated on the average ten tons to one, the concentrates averaging from 60% to 68% of tungstic acid. Practically all of these concentrates are shipped East, where they are treated chemically and reduced to the black tungsten metal or powder. Other portions are used directly in the manufacture of the fused metal or in the ferrotungsten alloy.

Chaffee County.

Ore is being shipped from the first vein cut by the Latchaw tunnel being driven in Mount Princeton under the direction of C. N. Sharp of Buena Vista. Stoping is to be started in other veins cut in drivings of 3000 feet.

Custer County.

The Hessite G. M. Co. is said to have struck rich ore at a depth of 50 feet on the Evening Star lode, near Silver Cliff. Manager M. S. Olin will sink the shaft 100 feet deeper.

Gilpin County.

Peter Daly and James Cody of Central City are developing the Mountain Lion, Elk and Alice Taylor lode claims, up Elk creek, by means of a tunnel which has been driven in on the Mountain Lion vein 175 feet.——It is reported that five stamps are to be added to the mill of the Mountain Monarch M. Co., near Rollinsville.——Grading is being done near Rollinsville for the new mill of the Penobscot M. & M. Co. The new mill is to be located below the tunnel entrance, and will be a 10 rapid-drop stamp amalgamating and concentrating mill. A 4-drill air compressor is to be put in, as well as a 100 H. P. boiler, in the new mill building. P. J. Hamble is manager.——Buress & Dowd of Denver have taken an option on the Copper King, in Lump gulch, and are preparing to unwater the main shaft, preparatory to putting in hoisting machinery. The mine is owned by Lunwall & Sons of Central City.——The Imperial M. & M. Co., operating the Mackey and Sarah Jane mines and the Mountz and Palmer mill, at the junction of Elk and Pine creeks, near Apex, has consolidated the holdings of the Cyrene Gold Mines Co., owning the Cyrene, Cyrene Extension, Jack Middleton, Clara Gees and Cronje lodes, in Twelve Mile and Elk Park sections of the Pine Creek district. The work on the Cyrene group at Twelve Mile is rather prospecting, a shaft having been started from surface. Operations were until recently carried on in the main shaft, but were suspended on account of there being too much water to handle. The hoisting engine formerly at the Mackey mine is being removed to the Cyrene shaft, and Manager Mountz has bought a 30 H. P. boiler and a new shaft building will be built. At the Mackey mine the small hoist formerly used has been taken out and will be replaced by the larger hoisting rig from the Cyrene mine in Twelve Mile. The levels at a depth of 150 feet are being extended both ways. The main shaft is down 250 feet, and they intend after the heavier machinery is in place to sink 200 or 300 feet during the winter.——The Fostoria G. M. Co., who leased the right of way to work their property in the Pleasant Valley district, 2½ miles south of Central City, through the Hudson Burr tunnel, have commenced drilling. The mouth of the tunnel is in Clear Creek county and cuts Nighthawk mountain. Before striking the vein of the Fostoria, the company will have to drive 400 feet. They will cut the Fostoria vein at a depth of 600 feet. W. E. Campbell has charge.——The Pleasant Valley M. & M. Co. has graders making preparations for the switch to connect the Gilpin tramway with the Banta-Hill properties.——C. E. Hurlbut of Downsville, N. Y., has purchased a one-half interest in the Great Divide claims, in Mammoth gulch, the other half interest being owned by A. M. Willard of Gilpin. Development is being done by a tunnel now in over 175 feet.——The Portland-Dow M. Co., in developing their claims in Moon gulch, have driven their tunnel 600 feet. Superintendent C. L. Dow reports that they have cut five veins.——Development work is being carried on in the Gauntlet mine, on the east end of Quartz hill, by the Gauntlet M. Co., with L. D. Hobson as manager.

Clear Creek County.

An important strike has been made in the Marshall tunnel, near Georgetown, through which the Colorado Central–Aliunde property is being worked by F. A. Maxwell. The strike was made on company ground and in the east drift recently started on the Aliunde vein No. 2. Considerable zinc is contained in the ore. The first shipment by the lessees from the 1000-foot level has been made by McClusky & Cottingham. John Beyo & Co., operating to the east, expect to start shipments soon. The winze, which was being sunk for the purpose of proving up disputed ground, has broken through and a big body of medium-grade ore is exposed. This ground is being worked out as fast as possible in order to enable Haggart & Patton to cover the winze. —— It is reported that the Vesper group, near Georgetown, will be turned over to Chicago men. D. W. Shepard and E. Williams, owners of the property, are employing men in development work. —— C. G. Mety of Denver has a lease and bond on the Gladstone–Cardigan mines, south of Idaho Springs. W. S. Mety has been placed in charge of the mine work and also the Allan mill on Chicago creek. This mill has been secured under lease for the purpose of running the mill dirt from these properties and such custom ores as may be offered. —— The Mount Theresa G. M. Co. has been formed by A. D. Bullis, C. Arthur and W. E. Garver to operate the Consolidated Moore and Big Chief groups on Mount Theresa, 1 mile south of Idaho Springs, on Soda creek. The company plans to put in a power plant on Soda creek and drive its machinery, hoist, pumps and drills by electric power. An ore shoot exposed in the Moore tunnel will be explored by sinking a shaft. The Moore tunnel is heading toward the ground of the Lexington and Preacher lodes. —— The tunnel on the Little Richard mine is in 2000 feet and two machine drills are forcing it ahead toward the ground on the Lexington vein. G. L. Bingham is manager.

Gunnison County.

The Elk Mountain Pilot of Crested Butte reports a strike of $35,000 gold ore on Cross mountain across Taylor river from the Doctor mine. —— The Doctor mine is to be reopened and operated by some Swedish miners.—— A strike of ruby silver ore is reported near Marcellena mountain.

The Midland mine, south of Gunnison, has been leased and bonded to the Spring Valley Gold M. & R. Co. The cyanide process has been adopted in the mill and the company is treating ten tons per day. The company is driving a tunnel to cut the ore below the shaft 100 feet. It will be driven 1300 feet.

Lake County.

J. W. Bailey of New York has a five-year bond and lease on the Grand Trunk group in the Holy Cross district, near Leadville, and will develop the property. The main tunnel is in 2050 feet, and from a point in this tunnel a crosscut drift will be run 350 feet to tap the chimney of ore opened in the upper tunnel.

T. J. Cash and associates, lessees on the Triumph, Jonny Hill, Leadville, have a lease on the Irene, a parallel claim, and are making preparations for development. The property has not been worked for ten years, the last being the driving of the lower drift, when, it is said, the fault was cut.

Ouray County.

The Atlas M. & M. Co. of Ouray has decided not to build its mill this year. Most of the machinery, dismantled from a mill in Rio Grande county, is laid down near the company's mill site. Instead, the company has rented the Governor 10-stamp mill for three months and will make 50-ton test runs on the Atlas surface ores, as well as upon those of the Mogul, Gilpin county and other lode claims adjoining the property.

San Juan County.

Superintendent A. A. Lamont of the Boston & Silverton M. & R. Co. reports that there is yet 400 feet more of tunnel to run to tap the Uncle Sam vein on the company's property 2 miles up Cement creek from Silverton. This will make the length of the Yukon tunnel bore 2300 feet into the mountain, and the Lamont tunnel on the same group is now into the hill 900 feet.

In level No. 1 of the Highland Mary in Cunningham Gulch, near Silverton, twenty men are developing the new strike.——The Frisco M. Co., working in the Mineral Point section, near Silverton, has let a contract for 5000 feet of tunnel work.

On November 1, the Animas Power Co., with its electric plant located at Rockwood, 25 miles south of Silverton, at the mouth of Cascade creek, will turn on the current and begin supplying the mines of San Juan with the cheapest and most effective power they have had.

San Miguel County.

It is planned to connect the mines of Marshall and Savage basins in Telluride district by an electric traction line, with the chief shipping station of the Denver & Rio Grande Southern Railroad at Telluride. It will connect with the Tomboy, Smuggler-Union, Japan–Flora and Liberty Bell mines, conveying the ores to the mills at Pandora and concentrates to the Rio Grande cars for shipment to the smelters.

Wagner Brothers are increasing their operations on the Smuggler & Sheridan dumps of the Smuggler & Sheridan mines, near Telluride, and the 76 claims on which they have a lease, and are employing 100 men. The dump ore is put through a Crane separator, and then transported over the Smuggler-Union tramway to the Smuggler 80-stamp mill for treatment.

Summit County.

At the Old Union mine on Mineral hill, Breckenridge, more men have been put to work and considerable ore is being opened up in the Moore tunnel. The mill is running steadily.——The Briar Rose properties, on Peak Ten, 5 miles southwest of Breckenridge, have been sold to the Parker Syndicate of Memphis, Tenn., by C. A. Finding. The property, while inconvenient to get to in the winter season, has been a producer of high-grade silver ore. They propose to open the mine with a lower tunnel.——The Hoosier Creek G. M. Co. have struck a vein of gold-bearing pyrite in a crosscut at the 110-foot level.——G. C. Smith, who is operating the Charlie Ross property at the head of McCullough gulch, near Breckenridge, reports striking a new silver-lead vein. At the surface the vein, which has been named the Crater, shows partly oxidized lead ore that shows indication of silver chloride.

Teller County.

A depth of 300 feet has been reached by lessees in the shaft of the Beacon hill Ajax, near Cripple Creek, and at that depth a station has been cut and a crosscut started toward the vein. —— It is probable that work will be resumed on the Perrault group on Mineral hill. ——It is reported that a leasing company will start work on the Extra Session claim of the Grace G. M. Co. of Cripple Creek, putting up a mill and sinking a shaft from the 200 to the 300-foot level. —— Chas. Weider has leased the Finn claim of the Royal Oak of Cripple Creek and proposes to sink the shaft from the 200 to the 400-foot level. A steam hoist is to be put in. —— Articles of incorporation for the Dark Horse M. & L. Co. have been filed by T. R. Cudahy, E. Mitchell and C. L. Bailey. The principal office is Central City and the place of operation Teller county. The company has leased the Flying Cloud, Sarah Ann McDonald, Royal Age and part of the Brinsmaid. The Flying Cloud lies on the southeast slope of Bull hill and near Pinnacle park. Several veins have been exposed from the surface to 100 feet deep, and one of them has surrendered ore. The latter body had a width of from 2 to 3 feet and a metallic content varying from pay to $30. —— Arrangements are being made by the Oro Mines Co., lessee of the Oro claim on the north slope of Ironclad hill, Cripple Creek, to put in a steam hoist. As soon as it is in commission sinking will be resumed. Machine drills will be used in the work. The shaft has a depth of 80 feet. It will be continued to the 300-foot point. —— Hodges & Taubert, leasing on the Little Clara claim of the Work Co., will use machine drills in their prospecting work. They reach the Little Clara through the Moffat tunnel. —— Shipments are to be resumed from the Maybeso mine on Squaw mountain, near Cripple Creek, by Bateman & Co., lessees.

IDAHO.

Boise County.

Manager G. Z. Edwards of the Lincoln Co. of Pearl says the first half of the new cyanide plant with which the properties are being equipped is ready to go into commission with the second half to follow soon. It has a crushing capacity of 150 tons daily. On the 340-foot level he has drifted on gold-bearing ore with some silver and of uniform value for over 200 feet.——Near Pearl a mill is being constructed by the owners of the Black Pearl group, in which much ore has also been blocked out, while another plant has been started at the Osborne group.

Elmore County.

B. J. Erwin, vice-president and general manager of the Provident Investment Co., owner of the Mountain View mine at Pine, reports that a vein of high grade ore has been cut at the Mary Glenn. Work will be continued all winter in charge of Theodore Knutson. For the Mountain View mine, Erwin is putting in an electric power plant on Lime creek. It will have a capacity of 400 H. P. and will be completed ready to run the Mountain View mill within two months. The Mountain View has an 80-ton mill.

Idaho County.

A big strike was recently made in the Jumbo claim, near Grangeville, on the 850-foot level. Milling has begun on the new ore.

Kootenai County.

D. W. Casseday, president of the Panhandle Smelting Co., expects that the smelter being built at Ponderay, 1 mile from Sandpoint, will be finished within a month. This is a 200-ton custom smelter built to treat the ore from the mines near Lake Pend d'Oreille. These include the Minerva M. Co.'s mines near Granite creek, on the east side of the lake, which produce lead-zinc sulphides and gray copper ore; the B. R. & B. mine at Blacktail, producing silver-bearing gray copper ore, which has been opened by an 1800-foot crosscut drain tunnel under the management of J. A. Brown; the B. F. & H. mine near Blacktail, being opened through a 700-foot crosscut tunnel, and the Venezuela, Keep Cool and Weber mines near Lake View.

Lemhi County.

The deposits of nickel and cobalt in Lemhi county,

from which about sixty tons of ore produced in 1903 were shipped as a sample of the ore, did not produce in 1904.

Owyhee County.

The Owyhee Nugget says that the recent strike on the Ruth mine, near Silver City, and the finding of the main vein shows the wisdom of crosscutting a ledge when evidence of ore is to be found, closely connected with the vein. The Ruth mine was acquired by G. W. Westlake and J. Lewis, who proceeded to develop it according to modern methods. The Ruth is an old location, on the northwestern slope of War Eagle mountain. The formation is normal and metamorphic granite. The vein is split by altered granite which the previous owners mistook for the hanging wall, and development was confined to a small stratum of quartz accompanying the foot wall. A tunnel was driven on the ore streak 1100 feet and ore extracted which netted the owners a little over $65,000. The work cost about $30,000 and can be used to advantage, as the main ore vein lies 15 feet from the foot wall and plainly shows the comb structure of the fissure vein system. A shaft is being sunk on the property and drifting on the vein will be done on the 100-foot level.——The War Eagle Consolidated Co. has men cleaning out the old Oro Fino tunnel and the stopes between it and the Golden Chariot shaft, preparatory to pumping out. A. Buckbee has charge.

Shoshone County.

J. H. Nordquist has been given the contract to drive an 800-foot tunnel on the Bull Pen group, a copper property, near Wallace.

At the Idaho Giant, two miles south of Mullan, there are 1200 feet of tunnel, and men are drifting on the vein. A gasoline engine and blower have been put in for ventilating, and a larger force of men can now be employed. The present work is in following the vein, and the company expects to be under the ore shoot in three months.

MICHIGAN.

Houghton County.

The Rhode Island shaft, which was recently started for the Quick lode, has been discontinued before reaching rock, awaiting Franklin results on the Kearsarge lode. The eighth level from the working shaft is in 1200 feet in encouraging ground.

MONTANA.

Beaverhead County.

It is reported that silver ore has been struck in the New Departure mine, 10 miles south of Dillon. The mine is being operated by O. M. Best, John Mackey and W. A. Jones, all of Dillon.

Fergus County.

N. J. Littlejohn of Lewistown and A. S. Wright of Chicago have located 1100 acres of ground as placer claims between the Gold Reef property and Whisky gulch, near Gilt Edge. The land will be prospected with a diamond drill.

At Kendall the Cyanide G. M. Co. has been formed by W. A. Shauls of Kendall, E. Johnson of Portland and J. R. Cook of Spokane to conduct mining operations on property beneath the townsite of Kendall.

Granite County.

It is reported that President Paul A. Fusz of the Granite-Bimetallic Co. and C. D. McLure of the Combination M. & M. Co. have leased the Granite-Bimetallic mines at Phillipsburg, and will sub-let certain portions of them. Such sub-leases have been made to a few.

Silver Bow County.

(Special Correspondence).—The Hancock lode claim purchased by the North Butte Co. is but 500 feet wide and 150 feet long, but it is a valuable piece of ground, because it is probable that the copper vein of the Jessie mine runs through the Hancock. The latter lies west of and adjoins the Jessie, in which the North Butte has been mining ever since it acquired the Speculator properties. The company is trying to buy the Kentucky lode claim west of the Hancock. Another company is being organized to take the Berlin and Lynchburg mines.——The North Butte has been sued for $20,000 damages by a miner who was injured in the Speculator mine, and for which he blames the company.——The Washoe smelter at Anaconda is consuming 11,300 tons of material daily, consisting of 8000 tons of ore, 1300 tons of lime rock, 400 tons of coke, 600 tons of coal and 1000 tons of other materials. The company employs 2500 men, of that number 1850 being at work in the smelter proper and the others at the foundry, brick yard, etc. The daily average of ore shipped from Butte to Anaconda is 8000 tons, though it has reached as high as 10,400 tons in one day. The smelter is able to handle 12,000 tons a day. It seems probable that the Amalgamated Co. will make another attempt to get an injunction against the Minnie Healey mine, owned by United Copper, and stop work on the ore bodies claimed by the Boston & Montana, to apex in the Piccolo, Gambetta and Colusa lode claims. It has been the contention of the Boston & Montana that the big Colusa vein dips under the Piccolo and Gambetta and into the Minnie Healey and that the Heinze Companies which have been working the Minnie Healey have mined on the Colusa vein and not on a separate vein having its apex in the Minnie Healey ground. Last fall a suit for $5,000,000 damages, on account of ore alleged to have been taken from the Colusa vein, was brought against the Heinzes and a restraining order was issued from the court which caused a suspension of operation on the mine for several days, and then the injunction was set aside. Since then the case has been allowed to rest in court until a few days ago when another Heinze Company was added as defendant, and it was stated to be the intention of the Boston & Montana to push the case.——A large body of ore has been found on the 300-foot level of the Lexington mine, which runs 104 ounces in gold and 124 ounces in silver to the ton. The Lexington is a property of the La France Copper Co., which is being floated by F. A. Heinze, and is independent of United Copper. Mr. Heinze has just returned from France, where he had been for several months in the interest of his new company.

Butte, Sept. 18.

The Raven mine is shipping silver-copper ore from a depth of 1200 feet.——A raise is to be made from the end of the crosscut from the 2400-foot level of the High Ore to connect with the Mountain View shaft of the Boston & Montreal Co. at Butte. This is down 1800 feet.

MISSOURI.

According to H. F. Bain and E. O. Ulrich in a recent report of the United States Geological Survey, copper in the form of sulphides and carbonates has been found at many points in southern Missouri, and has been mined in several localities, notably in Ste. Genevieve, Madison, Shannon and Crawford counties. Very large deposits, rivaling those of the West, have not been found and are not to be expected. The character of the ore and the low cost of flux, fuel and labor make it possible to work some, at least, of the deposits with profit. The ores show a preference for certain stratigraphic horizons, and, being bedded, may be prospected with ease and economy. The common association of sulphides with specular iron of the sandstone region points to the advisability of the investigation of the old iron pits. In Shannon county the most favorable localities are along the contact of porphyry and dolomite at points where the conglomerate beds at the base of the latter fill in shallow basins in the crystalline rocks. In the disseminated lead district of southeastern Missouri copper occurs in connection with the lead, and at a few points can be saved to advantage.

NEVADA.

Elko County.

Work has been commenced on the Nevada Northern Railway, which is to connect Elko with Toano, giving the copper deposits about Copper Flat, Pilot Knob and Ely an outlet.

Lincoln County.

The Searchlight Parallel G. M. Co. is putting in a 12 H. P. gasoline hoist, ore cars, rails, blower, pipe and other material at their mine near Searchlight. T. D. Forney is superintendent. The shaft will be sunk to the 500-foot level. Stations will be cut at each 100 feet.——M. W. Hurt, of London, England, has bought the Esther group, near Searchlight, from W. A. Groffs, and will sink to the water level.——The Skylight, Moonlight and Starlight claims, near Searchlight, have been sold to F. Armond of Switzerland and London and J. Koebig of Los Angeles, by W. L. Colton, T. L. Henderson and L. Wheatley.——The shaft in the New Year's Gift ledge of the Duplex M. & M. Co., of Searchlight, is now down 45 feet. The company intends to start shipping.

Nye County.

Articles of incorporation of the Las Vegas Tonopah Railroad Co. have been filed in Utah. The incorporators are: William A. Clark of Butte, Mont.; R. C. Kerens of St. Louis, Mo.; J. Ross Clark, R. J. Waters and W. H. Comstock of Los Angeles, and C. O. Whittemore and Pennel Cherrington of Salt Lake City. The corporation has an authorized capital of $4,000,000, of which $500,000 has been subscribed, as follows: William A. Clark, $100,000; R. C. Kerens, $200,000; J. Ross Clark, $199,600, and each of the other incorporators, $100. The officers of the corporation are: President, J. Ross Clark; vice-president, C. O. Whittemore; secretary, W. H. Comstock; treasurer, R. J. Waters. As stated in the articles of incorporation, the object and purposes of the corporation are to construct and operate a line of railroad from a point of connection with the San Pedro, Los Angeles and Salt Lake Railroad at Las Vegas, Nev., by the most feasible and practicable route, through the counties of Lincoln, Nye and Esmeralda, to the town of Tonopah, Nev., with connections to the mining camps of Bullfrog, Beatty, Rhyolite and Goldfield.

Washoe County.

The Keystone Nevada M. Co., through C. H. Bovee, has purchased the Olinghouse mine and mill, in Olinghouse Canyon.

NEW MEXICO.

Grant County.

On a claim between the Baltic and Flagler at Chloride Flats, near Silver City, a rich gold strike was made recently by Manuel Taylor and Ernest Oughton.

Otero County.

Arrangements are being made to put in washers and amalgamators south of Baird hill at Jarilla by Wells & Bohardt on their placer grounds. The Electric M. Co., which has 100 acres of placer ground, is also preparing for active work.——A contract has been let to sink the Garnet shaft at Jarilla from the 450-foot level to a depth of 500 feet.——An incline shaft has been started from the 690-foot level of the Nannie Baird mine at Jarilla. The incline follows the center of the vein.

OREGON.

Baker County.

Work is to be resumed on the Ross Gulch mine, owned by Basche & Stern, 2 miles southeast of Greenhorn.——Rich ore has been cut by the 50-foot shaft at the Pyx mine, near Greenhorn. The shaft will be sunk to a depth of 100 feet and crosscuts driven.

Josephine County.

N. E. Emerson is getting the Dutch John placer mines ready for the winter run. The mine is on the south bank of Rogue river, between Shan and Pickett creeks, near Grants Pass. The equipment consists of two giants. The water supply is from Shan creek and 1800 feet of pipe is used to give the head of 180 feet.

The smelter and reduction plant for Rogue River S. & M. Co. is being built in Spokane, and will soon be ready for shipment to Grants Pass. Ground has been cleared on the site, by Rogue river, 3 miles above Grants Pass. A straight line copper and gold furnace, 36x89 inches, will be put in. A dam will be built across the Rogue, by the dumping of slag from the plant. Coke can be delivered at the furnace for less than $9 a ton. One ton of coke will reduce six tons of ore, thus making the fuel charge $1.50 per ton. The company estimates that it will cost 50 cents a ton to handle the ore at the smelter. The nearest smelter is at Waldo, 45 miles from Grants Pass.——A new mill has been put in at the Gold Pick mine at Sucker creek, near Grants Pass. Frank Fowler is manager.

SOUTH DAKOTA.

Lawrence County.

A government report on the mineral resources of the United States states that the tungsten deposits in South Dakota are found in the Black Hills in two localities—one almost immediately north of Lead, near the top of the high hill forming the divide between Gold Run and Deadwood gulches, and the other more to the south of Lead, on the divide between Yellow and White Wood creeks. The tungsten mineral is wolframite, and it occurs in an impure dolomite which is very siliceous and grades off almost into a quartzite. The wolframite is found in flat, horizontal, but irregular masses up to 2 feet in thickness, which frequently cover considerable areas, one having been observed to cover 20 to 30 square feet.

It is reported that 120 stamps are to be erected by the Columbus Co. at a convenient site near the main shaft in Sawpit gulch, Central City. The plant will be equipped with cyaniding devices.

Pennington County.

The Cuyahoga Co., near Keystone, has resumed work. Sinking on the main shaft is now in progress.——Otto and Albert Menger of Keystone are making experiments on the treatment of the tailings from the Holy Terror mill.

UTAH.

Juab County

The ore shipments from Tintic for the week ending Sept. 16 were as follows in carloads: Eagle & Blue Bell, 8; Swansea, 8; Eureka Hill (lease), 1; Godiva, 4; Gemini, 11; Bullion-Beck, 1; Centennial Eureka, 67; Ajax, 2; Carisa, 3; Grand Central, 5; Mammoth, 11; Victoria, 5; Total, 127.

Salt Lake County.

The Emma mine at Alta is being reopened under the direction of Manager Thomas of the Maxfield Co.

The Guggenheim Exploration Co. has begun prospecting the property acquired by the recent Utah copper deal with diamond drills. D. McCarty of Leadville, Colo., has been employed to sink holes at various points on the company's holdings. These holes will be sunk both in and out of the mines.

WASHINGTON.

Chelan County.

In the United States the two principal deposits of molybdenum that have been exploited are near Crown Point, Chelan county, Wash., and at Cooper, Washington county, Me. The deposit in Chelan county is 30 miles from the head of Lake Chelan, which extends for 60 miles in a narrow rock gorge from 2 to 4 miles in width. At the head of the valley the gorge extends westward from the lake to where rises a nearly precipitous granite cliff in which is the molybdenite deposit. The first tunnel was started 900 feet up the side of the cliff. The molybdenite occurs in a blanket quartz vein, which outcrops along the perpendicular granite cliff referred to for a distance of several hundred feet. It is nearly horizontal, but in places has an inclination of from 5° to 6° toward the west. The vein varies in thickness from 2 to 3 feet and has been opened by two tunnels, one extending 195 feet toward the northeast and the other 80 feet westerly. The molybdenite is found in the quartz in small seams up to several inches in thickness that appear to ramify through the quartz in all directions, and it has not thus far been found in the biotite granite which incloses the vein. The molybdenite occurs in flakes from minute particles to irregular masses, and also in crystals that, for molybdenite, are well developed.

FOREIGN.

AFRICA.

The production of gold at the Rand in August is officially announced at 428,581 ounces, the largest on record. The production in July amounted to 419,505 ounces, and the outturn in August last year was 312,277 ounces.

AUSTRALIA.

New South Wales.

G. D. Delprat's manager report for half year ending May 31, 1905, to the Broken Hill Proprietary Co., Ltd.: The tonnage of ore mined at Broken Hill was 296,730 tons, as against 324,535 tons for the previous half year. The cost of working during the period under review was approximately the same as in the previous half year, and the grade of the ore showed no appreciable difference. The 1000-foot level is now connected with Delprat shaft. A gallery is being driven northwards in this level in order to explore the northern portion of the leases, and this is now in about 50 feet. The 800-foot level is now supplying ore regularly. Delprat shaft has been sunk a farther 100 feet, preparatory to opening up the 1200-foot level, the total depth now being 1120 feet. Stewart shaft has been sunk a farther 105 feet, its total depth now being 755 feet. The whole of the sulphide ore was sent to the concentrating mills and the oxidized ore to the smelters. At the concentration plant an increase of 1% in the lead recovery was noted. Six new ball mills were put in for regrinding, with satisfactory results. The sintering works treated 61,786 tons of slimes from the two ore-dressing mills and 55,880 tons of sintering product were dispatched to the smelting works. Mechanical feeders were put in and several stoppages occurred owing to shortage of acid. The total quantity of tailings fed in was 41,292 tons, producing 12,851 tons of concentrates. The tailings resulting from this operation form a valuable material for underground filling; it is very cheap to handle and packs well. The capacity of the plant is now 4000 tons per week. The working costs have come down materially. Another chamber was added to this plant, making three in all. One Glover and two Gay Lussac towers have also been erected. Six hundred tons of strong acid were made during the half year. A furnace for roasting zinc

concentrates has been built and will be put into commission immediately. It is proposed to substitute for the present roasting plant a zinc roasting plant, which is expected to give cheaper acid, and at the same time produce roasted zinc concentrates, required for spelter. The magnetic separators were kept idle during this term, as the other process for the same purpose gave more economical and rapid results. An additional electric locomotive has been obtained for use in connection with the transport of mill tailings, and three of these locomotives are now at work. At the smelter at Port Pirie the new 600 H. P. engine and condenser for driving the blowers is now in regular work, and the two Green blowers are in position. One of the smelting furnaces was modified on new lines, and after a trial extending over several months it was found that the recovery was increased very materially and other advantages followed. All the other furnaces are now being modified on these lines; four are already completed and the others will be taken in hand at once. The following shows the quantity of ore treated in the smelters: Kaolin and siliceous ore (inclusive of purchased ores), 3600 tons; sulphide concentrates, 70,167; sintered slimes, 57,301; carbonate slimes, 3112. Total, 134,180 tons. In addition to the foregoing, there were retreated: Flue dust, 1028 tons, producing 3402 tons of lead; raw matte, 409 tons, producing 324,590 ounces of silver; refinery drosses, 4955 tons, producing 2213 ounces of gold. Thus making the total quantity passed through the smelters 140,572 tons. The roasting plant treated: Concentrates and slimes, 70,608 tons; smelting ore and kaolin, 653; matte, 374. Total, 71,635 tons. The substitution of shell for limestone continues to yield good results. The refinery treated 34,838 tons of bullion, as against 35,851 tons for the previous half year, producing: Silver, fine, 2,638,588 ounces; gold, 1564 ounces; lead, soft, 33,195 tons; antimonial lead, 305 tons. The Dore plant treated 44,349 ounces, producing 1564 ounces of fine gold. At the limestone quarries at Point Turton all preparatory works are finished. Storage bins were erected, a flying fox put up, manager's house built and the jetty raised and lengthened. In future all our limestone requirements will be taken from here. A statement showing the total production, together with revenue and expenditure, since the inception of the company in 1835: Gross ore treated, 7,747,306 tons; lead produced, 733,025; copper produced, 4576; antimonial produced, 7201; silver produced, 129,740,728 ounces (fine); gold produced, 82,933 ounces. Receipts—Net amount received, £26,808,743; cash received for sale of blocks 15 and 16, £576,000. Total, £27,384,743. Expenditures—General working expenses, £17,123,774; depreciation, £938,999. Dividends and bonuses paid—From profits, £7,984,000; from sale of blocks 15 and 16, £576,000; from call made, £16,000. Total, £8,576,000. Reserve and insurance funds, £165,500; balance of profit and loss account, £580,470. Total, £27,384,743.

CANADA.

BRITISH COLUMBIA.

Boundary District.

The production of the mines of the Boundary for the week ending Sept. 16 was: Granby Mines, 11,371 tons; Mother Lode, 3808; Emma, 110; Providence, 20; Last Chance, 20; E. P. U., 40; Don Pedro, 20. Total for week, 15,389. Total for year, 619,172 tons.

Rossland District.

The Rossland Miner reports the tonnage of ore shipped from and crushed at the Rossland mines for the week ending September 16 was as follows:

Mine.	Week.	Year.
Le Roi	2,100	86,826
Le Roi (milled)	210	1,350
Centre Star	2,160	70,740
War Eagle	1,290	48,950
Le Roi Two	450	5,872
Le Roi Two (milled)	...	7 030
Spitzee	...	4,809
Velvet-Portland	...	1,977
Gopher	...	180
Homestake	...	30
Lily May	...	90
Inland Empire	...	30
Cascade-Bonanza	...	60
White Bear	...	1,100
White Bear (milled)	...	2,920
Crown Point	60	180
Jumbo	300	7,629
Totals	6,570	239,773

At Le Roi ore shoot on the 1550-foot level values continue to be about $15 to the ton, while the shoot is developing in a satisfactory manner. The dimensions of the shoot will not be known until considerably more work has been done. Drifting and crosscutting on the shoot is in progress. The Black Bear ore shoot, where it has been found on the ninth level, is looking well, and promises to yield a large tonnage of ore.——At the Le Roi Two the shoot on the fifth level is looking very well and will yield a good-sized tonnage. The other portions of the mine are developing well, and it is stated that at present the Josie is looking as well as it ever did in its history. The shaft that is being extended from the 900-foot level is making good progress. The 250 H. P. electric motor which is to be used in sinking the shaft from the ninth level has not yet arrived.—— The Spitzee has closed down pending the completion of the reorganization. Under this the company shares are made assessable, and the funds realized from the assessments will be ample for all requirements to place the Spitzee upon a profit making basis. The shut down will be short.——At the Center Star the main shaft has reached the tenth level and is being extended from the tenth to the eleventh level. At the rate of progress which is now being made it will not be a great while before the 2000-foot level will be reached. This will be level with the Columbia river and on the level of the water line. —— The Le Roi concentrator has started up. The management of the Le Roi states that the concentrator is doing better work than ever. Since the concentrator started operations tests on a large scale with several hundred tons of ore at a time were made, and in each instance the smelter returns suggested changes. These changes have increased the efficiency of the plant. The Le Roi 2 concentrator continues to treat second-class ore, concentrating it at the ratio of 20 to 1.

Nelson District.

The Nelson News states that the Hendryx cyanide plant has been successfully tested at the property of the Reliance G. M. Co., the values saved being 95%. The ore is received in a bin at the lower terminal of the aerial tram, 1700 feet in length. The coarse ore passes over a slanting grizzly, then to a Blake crusher, and then, with the ore that was already fine, passes between rolls 36x14. From the rolls, the crushed ore falls to the feed bin, from which, by gravity, it is passed into the Chilian mill. There it is reduced to pulp and mixed with a cyanide solution, which passes over amalgamation plates on which nearly 60% of the gold is saved. The liquid solution then passes through a series of ten storage settlers, and thence conveyed by launders to the Hendryx agitator. After from six to eight hours in the agitator the remaining gold values are on the plates that are contained in it. In the agitator the solution is continually exposed to the air by the revolution of the propellor, which hastens the separating process. The solution and the tailings pass from the agitator to a decanter, from the bottom of which the tailings are drawn away to the creek. The then clear solution of cyanide passes to a sump tank, from which, by centrifugal pumps, it is returned to the storage settlers, and from there to the original storage tank, so that the same solution is available for use again. The amount of cyanide required for the process is never more than a pound to a ton of ore, and averages two-fifths of a pound. The same solution may be used repeatedly, with small additions, and the cost of cyanide is 23 cents a pound. S. Lay, the company's superintendent and metallurgist, has increased the sensitiveness of the plates in the agitator by using galvanized plates. Hendryx is making a further improvement by enclosing the plates in a vacuum, covered with a filtering envelope. The vacuum will then draw only the clear solution to the plates and precipitate the gold. The mill treats ore from the May & Jennie mine on 49 creek.

Slocan District.

Work is to be resumed October 1 on the Fisher Maiden group on Four-Mile creek, near Silverton. The property is being opened up by tunnels.——Zinc ore has been struck in a tunnel being driven on the Grey copper claim, near Sandon, under the direction of J. A. Whittier.

Vancouver Island.

The Tyee Copper Co.'s smelter at Duncans Station ran twelve days during August and treated 2018 tons of Tyee ore, giving a return, after deduction of freight and refining charges, of $39,110.

Duncans Station, Sept. 16.

MEXICO.

Chihuahua.

The Almoloya M. Co., of which N. O. Bagge of Los Angeles, Cal., is the principal owner, and D. W. Shanks general manager, is putting in a 60 H. P. gas producer power plant for air drills and electric lighting at Sierra Almoloya. —— A hoist has been put in at the Johnson mine, near Santa Cruz.

The supreme court of Mexico has granted the injunction of Eduardo Barcenas, G. C. Harding and others against J. F. Johnston, the Stallforths and others restraining the award to the latter of their locations of 10,000 pertenencias known as the Bazatan denouncement in the Sierra Almoloya district. This scramble for locations on the 10,000 pertenencias mentioned was going on for several months, and in July last the property was to have been raffled off among 1400 locators. The mining agent at Santa Rosalia awarded it to Johnston, Stallforths and others, but the award was immediately enjoined in the federal court at Juarez, and this has been sustained by the federal supreme court to await trial on the merits of the case.

The Waterson G. M. Co., Ltd., at Ocampo has resumed operations after several months' shut-down to remodel the mill and put in a cyanide plant. This is the first cyanide plant to be put in at Ocampo.

Guanajuato.

The Peregrina M. & M. Co., operating the Peregrina mine at Guanajuato, is preparing plans for a new 100-stamp mill and cyanide tanks. The company now has twenty stamps and several cyanide tanks in operation. G. W. Bryant is general manager. —— T. H. Leggatt of London has bonded the El Cubo mine at Guanajuato from H. P. Hollis and associates of Chicago. —— The Guanajuato River M. Co. is preparing to put in centrifugal pumps, jigs and concentrators along the river, near Guanajuato. R. H. Ramsden is superintendent.

Jalisco.

The 30-ton experimental reduction plant at the Santo Domingo mine, near Etzatlan, is in operation. It is expected that within two months the exact treatment demanded by the Santo Domingo ores will be determined, and following that plans will be made for the proposed 100-ton plant. Manager Sustersic states that the erection of the big plant will be rushed. A new air compressor and ten new drills are to be put in.——The Independence M. Co., C. O'Brien manager, is putting up a 10-stamp mill at its properties, 25 miles southwest of Ameca.

Michoacan

Contracts have been made for fifty additional stamps for the reduction plant at the Dos Estrellas mine at Tlalpujahua.

Sonora.

(Special Correspondence).—The Minas Nuevas mill at Alamos is working full blast and giving satisfaction. The new electric-light plant is in, and the underground work is being pushed.——The shaft of the Santo Domingo mine at Alamos is down to a depth of 300 feet, and is now crosscutting to the lode on the east side of the shaft. ——The Quintera, at Alamos, is working full blast, and the smelter is turning out rich matte. Seaboldt is in charge of the smelter. Superintendent Ortiz is running a tunnel west, between the Quintera and Santo Domingo.

Alamos, Sept. 12.

The Yaqui S. & R. Co. is putting in a new reverberating furnace at Toledo. It will have a daily capacity of 100 tons of calcined ore.

Work at the Concordia copper mines, east of Hermosillo, is progressing favorably, with ten men at work under Superintendent C. H. Rankin. —— The mill at Minas Nuevas, Alamos, having been overhauled and repaired, is running full blast.

The Arizona M. & D. Co. has decided to build at Naco, Sonora, a 10-stamp mill to treat the ores of the Gold Treasure mine, 8 miles distant. E. T. Sparrow is general manager of the company, and Charles McHenry is superintendent.——The Democrata Cananea-Sonora C. M. Co. of Cananea is preparing to put in a new furnace with a daily capacity of 300 tons of ore, and to resume production again. The Democrata has nearly 2 miles of underground workings, which has exposed a large ore body. P. F. Hook of Cananea is the superintendent.

SOUTH AMERICA.

Peru.

The Cerro de Pasco M. Co. continues to work in the shafts already sunk, and is prospecting the Cerro de Pasco district and in the districts of Goyllarisquisca, Quishuarcancha and Vinchuscancha by means of diamond and other machine drills. The company has finished the construction of the railway from Oroya to Cerro, which is now open for public traffic. A branch line has also been constructed for 9 miles from Cerro to Vinchuscancha. It has also constructed branch lines to its shafts for the transportation of ore from the mines to the large smelter now being built at Tinahuarco, about 3 leagues from Cerro. This smelter will be finished within eight months and have a capacity of 500 tons per day.

Personal.

NORRIS ENGLISH is examining mines near Chloride, Ariz.

T. A. RICKARD has returned from Halifax, N. S., to New York.

G. P. UPTOS is manager Oro Grande mine, near Wickenburg, Ariz.

F. W. SMITH has resigned as manager Snow Creek mines, near Sumpter, Or.

J. M. CLEMENTS, of New York City, has been examining mines near Globe, Ariz.

W. H. WHITESIDE succeeds B. F. Warren as president the Allis-Chalmers Co.

WM. BARENSCHEER is superintendent Denver Ore Testing Works, Denver, Colo.

A. F. HOLDEN, a mining man of Salt Lake City, Utah, has been in San Francisco, Cal.

F. A. DARRENOUGHE has been made superintendent Shawmut Con. M. Co. at Bingham, Utah.

H. C. TABOR has been appointed superintendent Maud S. Gold M. & D. Co., at Cripple Creek, Colo.

F. J. CLARK has succeeded J. F. Heating as manager Butterfly-Terrible M. Co. at Telluride, Colo.

JOHN H. MACKENZIE of San Francisco has taken the management Le Roi M. Co. at Rossland, B. C.

MALCOLM MCGREGOR is superintendent Hermosa Copper Co., working near Hanover, Grant county, N. M.

SAMUEL FIELDS has been made superintendent Arizona-Mexican mines at Stockton Hill, near Kingman, Ariz.

A. F. HOLDEN, general manager United States M. Co., has been examining the company's new smelter at Kennet, Cal.

C. C. IRWIN has been appointed superintendent Goodenough M. & M. Co., working near Riggins, Idaho county, Idaho.

E. H. DAVISON, superintendent U. S. & Mexican Mining Syndicate at Santa Lucia, Sinaloa, Mexico, is in San Francisco, Cal.

MARK B. KERR has returned from Silver Peak, Nevada, and is examining mines near Cuyamaca, San Diego county, Cal.

C. P. OVERFIELD, western manager American Stoker Co., is in California en route to the Northwest, returning to Salt Lake City, Utah.

J. E. SPURR has resigned from the United States Geological Survey to become mining geologist for the Guggenheim Exploration Co.

R. P. WHEELOCK has resigned as superintendent Enterprise M. R. & I. Co., but will continue assaying and laboratory work in Kingman, Ariz.

W. J. WATSON has been appointed as manager Tyee Copper Co.'s smelter at Ladysmith, Vancouver Island, B. C., in place of Thomas Kiddie, resigned.

JOHN E. ROTHWELL, engineer with the Colorado Iron Works Co., Denver, Colo., is making an extended trip through the Black Hills and the Northwest.

JOHN GROSS, formerly manager the Horseshoe mill, Lead City, S. D., has formed a partnership with Louis Cohen and opened an office in the Jackson block, Denver, Colo., as metallurgists and mining engineers.

Obituary.

E. G. MORRISON, a mineralogist, was accidentally killed at Los Angeles, Cal., Sept. 17.

Books Received.

"Advanced Mechanical Drawing," by A. P. Pierce, will prove valuable to students wishing to know why they conform to certain practices in their work. The treatment is concise and practical. The author opens the theoretical instruction with a chapter on isometric drawing and cavalier projection, continues with a discussion on shadows, and concludes with a chapter on perspective. The problems are well chosen. The text is for advanced students and corresponds to the second year's work in a college course on descriptive geometry. It is published by John Wiley & Sons of New York City and will be sent postpaid by the MINING AND SCIENTIFIC PRESS for $2.

There are few technically educated engineers of to-day who have not at some time advantageously consulted "Mechanics of Materials," by Mansfield Merriam. The fact that a tenth edition is necessary and has appeared is in itself good evidence that the author's treatment of this important subject has been appreciated throughout the past thirty years. In this time many advances have been made in this important branch of engineering, making necessary certain additions and in many cases a more extended treatment. The subject is introduced by a discussion of elastic and ultimate strength, explaining the simple stresses and their varying effects on different materials. Then various beams, columns and shafts are discussed and analyzed, the principles explained being illustrated by a number of practical problems. This part of the book is much like previous editions, but the subjects of impact on bars and beams, resilience and work, and apparent and true stresses have been changed with the intention of rendering the presentation more clear and accurate. Among many new topics introduced are those of economic sections for beams, moving loads on beams, constrained beams with supports on different levels, the torsion of rectangular bars, compound columns and beams, reinforced concrete beams, plates under concentrated loads, internal friction, rules for testing materials, and elastic-electric analogies. A few changes in algebraic notation have been made in order that similar quantities may always be designated by letters of the same type, Greek letters being used only for angles and abstract numbers. Compared with the ninth edition, the number of articles has been increased from 151 to 188, the number of tables from 8 to 20, the number of cuts from 85 to 250, and the number of problems from 222 to 305. The length of each page has been increased 8%, smaller type has been used for formulas and problems, and the number of pages has been increased from 378 to 518. The main purpose in rewriting and enlarging the book seems to have been to keep it abreast with modern progress. The treatment is mathematically concise, yet detailed enough to be clear to the student. It is published by John Wiley & Sons, New York City, and will be sent postpaid by the MINING AND SCIENTIFIC PRESS for $5.

Commercial Paragraphs.

THE Standard Machinery & Supply Co. has been organized to handle mining and other machinery at 427-29 Mission street, San Francisco, Cal.

F. J. FROST AND JOHN C. HALL have opened a brokerage office in the Cooper Building, Denver, Colo., and will sell various kinds of mining machinery. They now represent several Kansas City firms.

THE Denver, Colo., office of the Crocker-Wheeler Co. are furnishing four large motors for the new tube mills at the Portland Cement Co., Portland, Colo., and have the contract for the electrical apparatus for the paper mills at Denver, Colo.

L. S. PIERCE, Denver, Colo., has recently received orders for his amalgamators from the Black Pearl M. Co., Pearl, Idaho; Alice M. Co., Boise, Idaho; J. H. Bemis, Quartzsite, Ariz.; U. S. Mint at Denver, Colo.; J. H. Reilley, Johannesburg, Cal.; Z. A. Harris, Red Rock, Mont.

THE California Ore Testing Works, 559 California street, San Francisco, has recently sampled a car of high-grade tungsten ore shipped to them en route for Germany, where it is used in the manufacture of armor plate. The ore is from the southern part of the State and will be followed by other shipments.

THE Geo. W. Lord Co., Philadelphia, Pa., have resumed shipment of Lord's boiler compounds to Japan and Russia. They report that since the signing of the treaty of peace, in addition to filling standing orders, they have received from their Vladivostock agent an order for a carload of compound to be shipped direct.

W. S. DORAN, formerly associated with the British Westinghouse E. & M. Co., Ltd., has been appointed manager of the power department of Allis-Chalmers Co. He will have entire charge of the company's commercial affairs pertaining to reciprocating steam engines, steam and hydraulic turbines, condensers, gas engines, blowing engines for iron and steel blast furnace service, and rolling mill engines, with headquarters at the general offices of Allis-Chalmers Co., Milwaukee, Wis.

THE Sullivan Machinery Co., of Chicago, reports the addition of two branch offices to its list, one at Knoxville, Tenn., and one at Joplin, Mo. The Knoxville office, with quarters in the Houston Building, is in charge of E. L. Thomas, for several years connected with the New York branch. Rock drills, stone channelers and quarrying machinery are carried in stock. S. A. Allison, who has been the company's representative at Joplin for the past two years, now becomes district manager at that point. A stock of Sullivan compressors, rock drills and duplicate parts and supplies is carried at the company's warehouse at Joplin. The new office is in the Keystone Hotel Block, corner of Fourth and Virginia avenue.

Trade Treatises.

Chas. C. Moore & Co., engineers, 63 First street, San Francisco, Cal., have issued a handsome and interesting illustrated description of "Gas Engines." Concisely, yet thoroughly, the construction and operation of Alamo and National gas and gasoline engines are explained. These engines are of the 4-cycle type.

Latest Market Reports.

SAN FRANCISCO, September 22, 1905.

METALS.

SILVER. — Per oz., Troy: London, 28⅜d (standard ounce, 925 fine); New York, bar silver, 62½c, refined (1000 fine); San Francisco, 62½c; Mexican dollars, 47c, San Francisco; 47c, New York.

COPPER. — New York: Standard, $16.35; Lake, $16.00@16.25; Electrolytic, $16.50; Casting, $15.75@16.20. San Francisco: $16.50. Mill copper plates, $17.50; bars, 18@24c. London: £69 5s spot per ton.

LEAD.—New York, $4.90; Salt Lake City, $3.60; St. Louis, $4.50; San Francisco, $5.00, carload lots; 5½c 1000 to 4000 lbs.; pipe 7½c, sheet 8, bar 6¾c. London: £14 6s ℔ long ton.

SPELTER.—New York, $5.95; St. Louis, $5.75; London, £26 10s ℔ ton; San Francisco, ton lots, 7c; 100-lb lots, 7¼c.

TIN.—New York, pig, $32.00@32.10; San Francisco, ton lots, 34c; 500 lbs., 35c; 200 lbs., 36c; less, 37½c; bar tin, ℔ lb., 40c. London, £145 10s.

PLATINUM.—San Francisco, crude, $18.50 ℔ oz.; New York, ingot, $20.50 ℔ Troy oz. Platinum ware, 75@$1.00 ℔ gram.

QUICKSILVER.—New York, $40.00@$40.50, large lots; London, £7 2s 6d; San Francisco, local, $38.50@39.00 ℔ flask of 75 lbs.

BABBITT METAL.—San Francisco, No. 1, 10½c; No. 2, 8c; No. 3, 7½c; extra, 17½c; genuine, 32½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 22.00c; San Francisco, Plumbers', 100-lb. lots, 19.15c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb, .04c.

NICKEL.—New York, 55@60c ℔ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 33@37c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c ℔ lb.; 100 lbs.. 35c; 1000 lbs. 34c; ton lots and over, 33c, Pittsburg. No, 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $15.50; gray forge, $16.50; San Francisco, bar, 3½c ℔ lb., 3¾c in small quantities.

STEEL.—Bessemer billets, Pittsburg, $21.00@$24.00; open hearth billets, $23.00@$25.00; San Francisco, bar, 7c to 13c ℔ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 7¾c; less than 500 lbs., per lb., 8c; in 25-lb. tin pails, ½c ℔ lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LIME.—Santa Cruz, $1.35 country, $1.25 city ℔ bbl.

CEMENT.—Imported, $3.00@4.00 ℔ bbl.; California, carload lots, $1.80 f. o. b. at works; small lots, $2.10 ℔ bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

LUMBER.—(Retail): Pine, ordinary sizes, $24.00@5.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50@5.00; pickets, $21.00;shingles, $2.50 for No. 1, and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00@35.00.

NAILS.—This week the basic prices are: Wire, $2.77; Cut, $3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d, Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4d and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 13½c; Hallett's, 14½c; San Francisco, 1000-lb. lots, 14c; 300@500-lbs. 12c; 100-lb. lots, 13c.

BISMUTH.—Subnitrate, ℔ lb., $2.10.

BONE ASH.—Extra No. 1, 5@6c ℔ lb; No. 1, 4@5c.

BORAX.—Concentrated, 7@8c ℔ lb; powdered, 9@10c; fused, 25@30c; crystal, 7c.

CANDLES.—Spear Brand, 16 oz. adamantine, 40s., 11c ℔ set; 14 oz. adamantine, 40s., 10c; 12 oz. adamantine, 40s, 9c; 10 oz. adamantine, 40s, 8c; 16 oz. stearic, 40s, 12¾c ℔ set; 14 oz. stearic, 40s, 11½; 12 oz. stearic, 40s, 10½c; 10 oz. stearic, 40s, 9½c. 100-case lots and over, ½c less. Not less than 50-case lots, ¼c less. Boxes of 20s, price ½c advance.

CAPS.—3x, $5.50@6 per 1000; 4x, $6.50@7; 5x, $8@8.50; Lion, $9@9.50, in lots not less than 1000.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c ℔ lb.; caustic soda, in drums, 3@3¾c ℔ lb.; Cal. s. soda, bbls., $1.10@1.20 ℔ 100 lbs.; sks., 90c@$1.00; chlorate of potash, 12@13c; nitrate of potash, 6¾@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2½@2¾c; flour sulphur, French, 2¾@—c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 5½@5¾c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66° B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

CHROMIUM.—90% and over, ℔ lb., 80c.

COAL.—San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lot, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $8.50, long ton; Colorado Anthracite, $14.00. Coke, $11.50 per ton in bulk, $13.00 in sacks; Sunnyside, $8.50, long ton.

FIRE BRICK.—Domestic, carloads ℔ 1000, f. o. b., factory square, $25.00; soap and split, $22.50; arch and wedge, $27.50; skewback, $30.00; circle, $32.00.

FIRE CLAY.—Domestic, ℔ ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, $8.50.

FUSE.—Triple tape, $4.00 per 1000 feet; double tape, $3.50; single tape, $3.10; Hemp, $2.75; Cement No. 2, $3.00; Cement No. 1, $2.65, in lots of 3000 and up.

OILS.—Linseed, boiled, bbl., 64c; cs., 68c; raw, bbl., 61c; cs., 66c; Lucol oil, boiled, bbl., 51c; cs., 56c; raw-bbl., 49c; cs., 54c. Kerosene—Pearl, per gal., 17½c; Astral, 17½c; Star, 17½c; Extra Star, 20½c; Eocene, 19½c; Elaine, 26c; Water White, in bulk, 11c; Mineral Seal, iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 14½c, do., cs., 21c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 12½c; do., in cs., 19c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 57½c; cs., 62½c; Sperm, crude, 63@68c; Natural White, 68c; Bleached, do., 57c; Whale Oil, cs., 52@67c.

LITHARGE.—Pure, in 25-lb. bags, 9½@10½c ℔ lb.

MAGNESIUM.—Pure, N. Y., $1.60.

MANGANESE.—Black oxide, ℔ lb., 2¾@4c.

MERCURY.—Bichloride, ℔ lb., 77c.

MOLYBDENUM.—Best, $2.75 ℔ lb.

PHOSPHORUS.—American, ℔ lb., 70c.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1**, 50%, carload lots, 11¾c; less than one ton, 13¾c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2**, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

RED LEAD.—500 lbs. and over at one purchase, ℔ lb. 7½c; less than 500 lbs., 7¾c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 54c.

SODIUM.—Metal, ℔ lb., $1.

TUNGSTEN.—Best, ℔ lb., $1.20.

URANIUM.—Oxide, ℔ lb., $3.40.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING SEPTEMBER 5, 1905.

798,861.—HOISTING APPARATUS—C. J. Allen, San Francisco.
798,593.—FENDER—W. J. Birchell, Phœnix, Ariz.
798,664.—BELT LACING POINT—D. Daniels, San Francisco.
798,891.—BRAKE—G. Eisenkramer, San Francisco.
798,953 —STIRRUP—C. F. Eldenburg, Spokane, Wash.
798,603.—INSECTICIDE—W. D. Everette, Tacoma, Wash.
798,778.—NUT LOCK—C. C. Garrison, Truckee, Cal.
798,782.—BALING PRESS—W. H. Gray, San Leandro, Cal.
798,783.—UMBRELLA—B. M. Greene, Myrtlepoint, Or.
798,674.—AIR BLAST NOZZLE—J. Haas, San Francisco.
798,734—ARM SUPPORT—J. C. King, Callahan, Cal.
798,805.—COMPRESSING HAMS—H. A. Kurfiinke, San Francisco.
798,810.—RAKING APPARATUS—J. R. Lewis, Biggs, Cal.
798,744.—RAILWAY CROSSING—E. F. Meisner, San Francisco.
799,015.—MUFFLER—E. H. Moffitt, San Francisco.
798,623.—FIRE EXTINGUISHER—Poole & Bartlett, Pomona, Cal.
798,974 —WHEEL TIRE—W. C. Poole, Marysville, Cal.
798,977.—DUST CONVEYOR—I. A. Putnam, San Francisco.
798,701.—FISHING REEL—F. J. Rabbeth, Redlands, Cal.
798,979.—PLEASURE RAILWAY—J. C. Reckweg, Los Angeles, Cal.
798,926.—MOTOR TRUCK—C. Schmidt, San Francisco.
799,020.—OILER—E. A. Strause, Los Angeles, Cal.
798,840.—DECORTICATOR—J. B. Sutherland, Seattle, Wash.
798,755.—HYDRATING LIME—J. Thomlinson, Portland, Or.
798,715 —SCALE REMOVER—L. W. Thompson, Hobart Mills, Cal.
798,717.—SPIRIT LEVEL AND SQUARE—C. G. Weatherly, San Francisco.
798,088.—STEAM GOVERNOR—T. M. Wilkins, Seattle, Wash.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

SINGLE-TRACE HARNESS.—No. 799,294. Sept. 12, 1905. George V. Beckman, Lodi, Cal. This invention relates to harness, and especially to a harness for use in plowing or cultivating in orchards, vineyards and the like. Its object is to provide a simple practical means which will permit plowing or cultivating close up to vines and trees with no possible chance of breaking the vines or tearing the bark off of the trees, as so frequently occurs with the ordinary double-trace harness and whiffle and swingle-tree arrangement. It comprises a rigid trace member, having means for attachment to the horse and extending along one side and to the rear thereof, said trace member having a rigid lateral projection approximate to its rear end for the attachment of the plow or cultivator, and an evener appliance for said trace member.

GAS GENERATORS FOR EXPLOSIVE ENGINES.—No. 799,341. Sept. 12, 1905. Adolph W. Jones, Alameda, Cal. This invention relates to an apparatus for converting liquid hydrocarbons into a suitable gas for use in explosive engines. Its object is to provide an apparatus whereby may be produced a cheap practical gas, and which shall utilize the heat of the exhaust from the engine to assist in the vaporization of the hydrocarbons, such as petroleum distillate and the like, which are not very volatile under normal conditions. It comprises three concentric domes inclosing outer and inner gas chambers and an intermediate heating chamber, a source of heat for said heating chamber, means for delivering oil into the outer chamber to be vaporized, connections between the outer and inner chambers and connections between the inner chamber and the inlet of an engine.

Aetna Dynamite

Now for Sale in DENVER

This brand of dynamite has heretofore been difficult to obtain in the Western mining States because the entire product of the factory has been eagerly taken up in markets near home. Increased facilities for manufacturing now enable them to supply more distant trade.

To the man who has used it, "AETNA" means something extra in the way of quality and uniformity.

For Sale in Denver by Geo. T. Kearns, 520 McPhee Building.

MADE BY

Common Sense

teaches us that **RUBBER** against an article creates friction. In fact, we wear rubber soles—use rubber on steps, etc., to prevent slipping—to create friction.

Why do you use **ENGINE PACKING** with rubber on top—on the bottom—and in between—where it is rubbing against the rod all the time—creating excessive friction—loss in power—fuel—money?

No such mistake in

"EUREKA" PACKING.

The rubber is where it should be—embedded in flax—which takes the wear—the lubricants prevent friction.

Isn't it up to you to try **GENUINE "EUREKA,"** particularly as the price is one-half less?

THERE is no unsupported "theory" in our advertising columns. What there appears has cost millions in experiments; has been proved to be efficient and represents the most advanced state of the art.

MINING AND SCIENTIFIC PRESS.

Whole No. 2358.—VOLUME XCI. Number 14. SAN FRANCISCO, CAL., SATURDAY, SEPTEMBER 30, 1905. THREE DOLLARS PER ANNUM. Single Copies, Ten Cents.

THE prevalent lack of uniformity in the mining laws of the several States hampers mine development. Federal authority being paramount, the United States revised statutes applicable to mining take precedence, and in case of conflict overrule State legislation. There never can be the requisite uniformity in mining law that would best inure to the advantage of mining men until there is a national department of mines and mining with a Cabinet officer at its head, which is an additional argument for the necessity of the creation of such a department. This journal is credibly informed that President Roosevelt seriously contemplates in his December message to Congress a recommendation that such a department be created. If he does he will occupy even a higher place in the good will and affection of millions of his fellow citizens than he does at present. He is broad gauge enough to see that it is but a tardy act of justice to the American miner that such a department be created for the greater development of the greatest industry of the nation.

THE two new smelters to be built on the bay of San Francisco, Cal., together with recently increased facilities in existing plants, will tend to render unnecessary any further shipments of silver ore from Chile to Pueblo, Colo., via Galveston, Tex., a more direct form of transportation being conducive to economy. Fuel oil and improved transportation of necessary fluxes aid in such advance.

IN former years the geologist and the miner did not get along very well together, neither being in favor with the other. With mining and scientific advance, they realize how inter-dependent they are and how they can mutually aid each other. The geologist primarily collects his facts from the miner. The facts thus systematized and arranged are within the reach of every intelligent miner, who is of more value to himself by their use. Rudimentary knowledge regarding rock formation, forces past and present, the constituents of the rocks, the general relation of rock groups and their modifications are of economic value to the miner and are good examples of "applied science." "Science" is simply organized knowledge, and with the miner, as with everybody else, the more he knows about the business in which he is engaged the more valuable he is to himself and all concerned.

ON pages 226 and 227 is reproduced a graphic portrayal of the mineral and metal production of the United States from the years 1895 to 1904 inclusive, as furnished by the U. S. Geological Survey. It will be noted that the aggregate value of $1,419,288,117 in 1903 dropped in 1904 to $1,289,660,788, occasioned by the lesser yield in coal and iron. An increase in the gold and copper yield of 1904 over that of any other year therein specified is noted. From the $69,303,319 given as the value of the 53,603,000 troy ounces silver mined in 1904 should be deducted de facto $37,141,519, leaving $32,161,800. The former figure represents the coining value, the latter the commercial value at 60 cents per ounce. As in 1903, the value of the copper yield of the country exceeds that of the gold yield. The chart is interesting to every mining man and is reproduced in its entirety.

Developing Mine Prospects.

The present low rate of interest obtainable and the obvious profit in mining occasions a desire to invest capital, and there is existing demand for gold and copper properties. None but the very wealthy care for "going" mines, because a developed mine is usually worth more to its present owner than to any one else, unless he be offered an unusually tempting price, and a comparatively small amount will secure a good "prospect." A prospective mine is always an attractive proposition—provided it be opened up sufficiently to indicate some real value, something more than a mere "prospect," no matter how well located. One trouble is that when the original owner has opened up his prospect sufficiently to show that investment of capital would probably make a mine out of it he often gets the idea that he should have as much for it as though it were a developed mine, ready to yield ore in paying quantities. The point is that a little work in addition to that already done will enable many a prospect owner to make a showing that would justify him in asking a reasonable price with more likelihood of getting it. There are a great number of "prospects" (over 17,000 in the State of California), the vast majority of which cannot be considered in shape to show a possible purchaser, and as things go there is no form of work that would pay better than for the owner of an undeveloped prospect to put it in such condition, if possible, as to justify its examination with a view to purchase at a fair figure by one who has the money to make a mine if the makings of the mine exist. Of course objections will arise right here to this argument by many readers, the first being, "If by development I make my prospect valuable enough to be bought, why not keep on developing it and make a mine of it for myself?" By all means, if you have the money. If not, were it not well to let it go at a profit to some one who has? The other objection is an occasional one, and in the light of twentieth century business ideas is almost comic. It is, "If I do much more work on my prospect I will spoil it," which carries with it its own refutation.

Until recently the Eastern investor wanted only "going" mines; to this day the foreign investor discards the proffer of a prospect, and looks for a developed property paying present profit. Both Eastern and foreign investors looked at the matter just as they would in buying industrial stocks or bonds, for immediate dividends—a prospect or a partially developed property was not worth considering. The California or Colorado or other Western investor, on the contrary, has always shown a desire to get hold of a good prospect and develop it. Frankly, that is where the biggest profit lies. Almost without exception, every big mining operator has made most of his money by developing a good prospect. The great fortunes of the great miners living or dead were not made by buying developed mines, but by developing prospects into mines. It is in that way millions are made in mining, and one might almost say the only way.

In this connection the MINING AND SCIENTIFIC PRESS offers a suggestion. Instead of as now in so many cases waiting for "foreign capital" to come in, it were well for local capital to take hold. This is being done in a good way in Colorado. A good example of the same kind of work is afforded by the residents of Nevada county, Cal., where merchants, mine owners, working miners and others take shares, pay assessments and enable good mines to be developed, and when they are developed, keep the money in local channels, to the general profit of the entire community. In many a deserving mining district throughout this west half of America are owners of prospects awaiting "capital." The local bankers, storekeepers, office holders and others can, with a little effort, put up enough to develop a promising local prospect into a paying mine, and then own it themselves. And it may be said in no way could they quicker secure the wished-for influx of capital than in the manner indicated.

THE United States patent office has a yearly increasing surplus which should be devoted to the needs of that overworked and overcrowded department, instead of being piled up in the treasury. It was never intended that the patent office of the United States Government be a money-making proposition, and every dictate of justice and business policy is in favor of needed change in this matter. Inventions in mining and metallurgical appliances and machinery constitute a large percentage of the great number of patents weekly issued, and hence the subject is an important one to the mining and manufacturing industry. There should also be some radical changes in the present patent laws, which are as antiquated as the building in which the patent office business is conducted. No patent agent or attorney should be allowed to practice until he had passed an examination showing sufficient knowledge, and the myriad of shyster solicitors who prey upon inventors should be treated by the Government the same as other swindlers, who are denied the use of the mails and otherwise suppressed by the Government postal authorities.

Mining Stock Speculation.

There is lack of reason or judgment in the senseless cry one often hears against speculation in mining stocks. Nor is the fact that money may be lost in such speculation any business argument. Money may be lost in buying any kind of stock—railroad, industrial or other sort; it may be lost in purchase of city lots, or stocks of goods, yet people will go on buying these things. The cry is from timid souls or those who do not think. The point is that in any sort of speculation judgment is a necessary attribute. After careful study and observation, the man who speculates in mining stock is just as likely to win as though he speculated in anything else. His chances for success are as good; true, they are also as bad, but the business view of such things is to exercise all possible precaution and then be resigned to the inevitable element of uncertainty that enters into everything one can do. Men have made unfortunate speculations in matrimony, yet people go right on marrying and giving in marriage, as though there were no such thing as divorce courts or a domestic fight to a finish. In like matter it is said and sung that a bear is a bad element in the stock market. Yet he is just as necessary as the bull. The average man abhors a stagnant market; he doesn't care much which way the stock goes, up or down, just so there is something doing. He wants to get action for his money. It is neither our province nor our purpose to uphold or justify gambling in mining stocks, but it is to be remembered in connection therewith that some of the biggest and best mining enterprises in the world's history were made possible only by the active dealing in the stock. The public who followed its fluctuations knew little and cared less whether the ore shoot at the 800 level pinched out or the breast of the drift in the 1200 level was in bonanza, and when assessment after assessment was levied it was the public, by holding up the stock and paying the assessments, who furnished the funds necessary to prosecute the heavy and expensive dead work that made the mine so great an ultimate success.

PROMINENT among the things that help Western mining interests is the great present activity among the railroads. The "Moffatt" road, now building from Denver, Colorado, to Salt Lake City, Utah, will open up a new section of rich mining country to the certainty of development and increase of wealth that follows facility of transit. Of the "Clark" road from Salt Lake City, Utah, to Los Angeles, Cal., precisely the same may be said. This week comes news that that line is to be extended from Los Vegas, Nev., up through that State to Tonopah, Goldfield and other new rich camps of southeastern Nevada. By the "Hazen cut-off" the Southern Pacific has placed that same section in standard gauge railway connection with the rest of the world. The Western Pacific Co., which will build from Salt Lake City, Utah, to San Francisco, Cal., has begun actual work at both ends of the line on what will be practically a new transcontinental route, traversing for a considerable part of its length a mineral region hitherto isolated but susceptible of development similar to that enjoyed by other mineralized territory to which the railroad always brings life by suitable transportation. In Arizona the Santa Fe Co. is doing the same thing by numerous branches and connections. In the last six months

all of the above work has assumed tangible shape, and much of it has been accomplished. It means a great deal to the mining man, manufacturer, merchant, and the great numbers who always hail a newly opened country as a chance for the success that should attend honest effort.

Assessment Work and Patents.

The annual required $100 work on an unpatented mining claim to prevent it from lapsing to be again a part of the public domain and thus subject to relocation, is not cumulative in its effect. One can do $100 worth of work or improvement on his claim every year right along, for twenty years, and if he omits so doing for any one year the claim is just as subject to relocation as if he had done no work thereon at all. If, on the other hand, he does no work on his mining location his "title" thereto is undisturbed so long as no one else thinks the claim is worth jumping. If he wants to take the chances on no one wanting to relocate it he can let the claim alone for as many years as he chooses. How the locator treats his claim is usually indicative of what he thinks of it himself. The better way is to do sufficient development work on it to entitle him to apply for a United States patent thereto. In case he wants to sell it such patent would be a splendid investment, for ability to show a title from Uncle Sam goes a good way with a buyer who is as careful in the purchase of a mining property as he would be in buying any other kind of real estate. The lenient requirement of all State and Federal enactments regarding annual assessment work is merely to incite development and discourage the pernicious practice of holding claims without working them. Discovery and appropriation are the sources of title to mining claims, and development by working, as a condition of continued ownership, until a patent is obtained, the latter being the ultimate intent.

Objection has been made to this journal against patenting a claim that it then immediately becomes taxable. Such argument is not tenable. While, as a matter of fact, it does "become taxable," the unpatented claim itself is subject to taxation, and even if the patented claim were taxed a few dollars every year, such amount would be much less than the $100 necessary annual assessment work. Those objections to patenting or even to the annual assessment work itself usually come from those who are trying to hold several claims without complying with legal requirements and endeavoring to hang on to more mining ground than they can legally work or claim. The spirit of the liberal law is that each man must make use of what he has or else give it up to somebody else. Whether it be the capitalist, the promoter, the speculator, the miner or the prospector, each has equal rights that must be respected.

The man who bonds or buys wants no question raised as to title, so that he can not be attacked by lawsuits that often crop up when the property becomes valuable, and in case he wants to sell or transfer the property "the ironclad potency of a U. S. patent" is most desirable.

Assessable and Non-Assessable Stock.

"Which is best, assessable or non-assessable mining stock?" is a question from a Colorado subscriber that merits editorial reply. The question involves matters of more interest commercially than locally, and in its broader sense is unaffected by made law. In Colorado and other States it is optional in the organization of a mining company whether the stock be assessable or non-assessable. In California all stock is by law issued only on the assessable plan. Whether it be Colorado, California or anywhere else, it is our belief that assessable stock is the best for all honest purposes. Non-assessable stock offers better opportunities for swindling. Because of this, some self-styled "mining men" object to assessable stock. It is largely a question of intent. Where a mining company is organized to make a mine out of a prospect, or to mine for the legitimate profits likely to result, an assessable stock is preferable. Should more money be needed, the stock can be assessed. In a non-assessable company, unless there is enough money at the start, there is ordinarily no way of raising it except by selling treasury stock, and, that resource failing, nothing remains but to shut the mine down or freeze the smaller stockholders out, for the knowing few to have the property sold at sheriff's sale and buy it in themselves. Mines must be made, and it takes money to make them. Equable assessment of the owners of stock therein is the best device ever invented for securing such necessary money. Of course, the custom can be abused, and has been many times.

Unjust or unnecessary assessments for stock jobbing purposes are not uncommon, but of late years the courts have thrown safeguards around the owners of assessable stock, and the directors are liable to be brought up short to answer why a receiver should not be appointed in case of any suspicious levying of assessments. As stated, the question resolves itself into one of intent. If the intent be to make a mine, assessable stock is better; if the desire be to swindle the public, the non-assessable plan presents superior possibilities.

As to "par values" of stock, there is a possibility on the part of the vendor of juggling with terms. "Par value" is an elastic term. The selling value more nearly represents the actual value, on the principle that a thing is always worth what it will fetch. There is nothing in the contention in some quarters that there should be a small par value on all assessable mining stocks, on the ground that assessments must cease as soon as the par value has been paid up in full. That used to be argued, and so used the statement be made that a mining company whose capital had been paid up in full by means of assessments could only continue to assess the stock by reorganizing with enlarged capital. But there is nothing in such argument. Assessments can be levied upon an assessable mining stock even after the capital has been paid up in full, provided the money so collected is put into the company's plant in the way of enlargement or improvement.

Better Roads Needed.

Throughout many mining districts there is a great and constant loss to miners, merchants and manufacturers because of bad roads. Ofttimes, especially in the winter months, there is a delay of supplies and machinery and an enforced stoppage of work because of sheer inability to transport goods. In the one State of California alone this loss is enormous. In regions ramified by narrow gauge roads it is not so appreciable, but where wagon roads are still depended on, the condition of such excuses for roads is ofttimes deplorable.

The reason for present allusion to this state of affairs is that the fall elections are coming on, and with the county residents of most of the districts so held back lies largely the remedy, which is to elect to the boards of supervisors men who will see that the roads are properly attended to. Public sentiment is not so lax in this regard as might be supposed, but, ordinarily, people forget their most immediate needs in the fuss and fight over who shall be sheriff or county clerk, or some other good paying position, and overlook the need of putting intelligent, broad gauge men in as supervisors. The ordinary county supervisor wants to see how little can be spent and how low the tax rate can be made. This, in the abstract, is a commendable idea, but it is not always good practice. The taxes levied by State and county lie less heavily upon a community than the tax levied by the residents upon themselves by lack of proper means of transportation. Economy is well, but it should be true economy—which is only another name for judicious expenditure of money. If necessary, five cents should be saved; but, if necessary, ten thousand dollars should be spent. Economy takes a more broad gauge view of things than the immediate "saving" of a few dollars in taxes. Such saving is often the most costly form of financial folly. This is generally understood, but, as stated, if in the coming elections the "German vote" or the "Scandinavian vote," or any other kind of vote be solely figured on in the effort to get some favorite son elected to a paying position, and the more important post of supervisor be thrown to geographical sections of the county "just to fill up the ticket," there can not be much improvement expected in the present backwoods system of roads in so many mining districts. As a cold business proposition it would pay. The saving in one year in the loss now entailed and the improvement in values would more than justify the slightly increased tax rate. The subject is a homely one, but of close concern to the mining industry, and those who have given any observation to it will concede that the remarks are as true as they are trite.

New Nevada Mining Camps.

The greatest present general interest in mining development still centers in the southeastern Nevada gold discoveries, even to the extent of railway building to the new districts. The gold is there and the country is "new." There is a charm about "a new mining country" that would call the prospector and the miner anywhere. Because it was a new country is what sent so many to the Klondike and to Nome. It is the lure of the new region that calls the miner. It was always so, and probably always will be.

In the early days of the world an altar was built to the rising sun, and that altar has ever been thronged with worshippers. Men have a feeling that in a new mining region their individual chances are better. When the news of Tonopah, Goldfield, Columbia, Bullfrog, etc., was first told, men instinctively felt that there was a new El Dorado with all that that implied. No matter that there were good mines and fine prospects elsewhere. In so many parts of the "elsewhere" matters had settled down to ordinary commercial requirements. There "one man's chances were as good as another's," and there thousands have flocked. When in 1901 and 1902 was told in these columns the extent and wealth of the new Nevada gold strikes it was felt that in the hazard of new fortunes lay larger possibilities of quick success, and since then new discoveries in that vicinity vindicate the faith felt in Nevada's revival as a mining State.

In the days of the first discoveries of gold in the famous mining camps of Tonopah and Goldfield, Nev., and the newer camps adjacent, much was said in these columns, and the press throughout the country has since spread the news to so great an extent that many have thought all they had to do was to go there and they would get on somehow. The general idea is not a bad one, but an unskilled man going to a new camp with intent to work the mine and not the street is often a misfit. A letter from Goldfield this week says there are "too many idle men here." That is always the case. There never yet was, and probably never will be, a rich mining camp without its undue quota of idle men, some from choice, many from necessity.

What is here meant to be said is, that while no advice is needed by the prospector or another class, who live by their wits, or skilled miners who can get on anywhere, the unskilled man who wants to earn daily wages working in a mine would do better to go elsewhere than to a new mining camp. He should choose an older mining district, for there exist more opportunities to learn and to get employment than in a new mining community, where men are obliged to depend to a greater degree on their own resources.

STRONG protest has been made for some time against the importation of foreign zinc ore under present conditions. Effort is being made by the Missouri & Colorado zinc mine operators to have the Government levy a 20% advalorem duty on zinc ore from Mexico and British Columbia, as present conditions tend to keep down the price of the ore. Another question affecting American zinc miners also comes up. The tariff provides that minerals crude or not advanced in value, not specifically provided for, shall be admitted free of duty, and that metallic mineral substances in a crude state shall pay a duty of 20%. There is a present effort to have definitely determined in which class zinc ore belongs; also whether lead-bearing zinc ores, which are subject to duty on the lead contained therein, includes the case where the ore contains so little lead as to simply appear in too small a quantity to justify commercial consideration. On the 21st inst. the Treasurer of the United States heard argument pro and con in Washington, D. C., on the subject, and turned the question over to the United States Attorney General for his opinion.

CONCENTRATES.

CAST iron in cooling contracts $\frac{1}{8}$ inch per foot.

USE a lower power explosive to lessen the amount of fines produced in blasting the brittle rock.

IT is best to admit air to the compressor as cold as possible and to the motor as hot as possible.

THE electro chemical equivalent of a metal is the weight in grams precipitated by a current of one ampere flowing for one second.

THE absolute scale of temperatures has its zero point 460.66° F. below the ordinary zero, or 492.66° F. below the freezing point of water.

THE burning of one pound of average crude petroleum requires 190 cubic feet of air and produces 19,500 B. T. U., 3.1 pounds CO_2 and 1.25 pound H_2O.

IT is incorrect to say "ore in sight" unless the ore body has been opened on three sides, e. g., two levels with a connecting raise shaft or winze all in ore.

TAR OR ROSIN should not be used on belts, as excessive power is required and the belt soon destroyed. Some graphite preparation would give good satisfaction.

TO CLEAN and remove the pencil lines from the tracing cloth apply a rag saturated with gasoline or benzine. Water will destroy the surface and render it unfit for use.

FOR single-hand drilling an octagon steel rod $\frac{7}{8}$ inch to $\frac{3}{8}$ inch in diameter is commonly used, with $\frac{5}{8}$ inch to 1 inch as limits; double-hand work requires a heavier steel.

THE melting points of gold and silver are 1065° C. and 962° C., as carefully determined with the hydrogen thermometer for use in standardizing the Le Chatelier pyrometer.

THE average gold extraction at Johannesburg, South Africa, is about 85% of the total gold contents of the ore sent to the mills. As high as 93% has been obtained in special cases.

A CUBIC FOOT of coal gas will sustain two-thirds of an ounce, avoirdupois, in mid-air. One hundred pounds at the surface of the earth would weigh 99.75 pounds 5 miles above the earth.

IF telluride and highly arsenical ores are very finely pulverized and no copper is present, an extraction of 90% to 98% is often obtained by using the filter press process without roasting.

SPROUTING or vegetation of molten silver when cooling is due to the escape of oxygen, which is absorbed during melting. It may be avoided by cooling slowly and keeping the surface warm.

TO get the horse power safely transmitted by a steel line shaft with bearings every 8 feet, multiply the cube of the diameter in inches by the number of revolutions per minute and divide by 75.

THE best way to distinguish the dolomite from the limestone is to touch the rock in question with a drop of dilute hydrochloric acid; if it effervesces strongly it is limestone, otherwise it is dolomite.

THE grease on the amalgamating plate is either from candle ends in the ore or the use of too much lubricating oil in the machinery. Caustic potash will remove the grease and benzine will remove the mineral oil.

EIGHT POUNDS of sulphur in iron pyrites has the same calorific power as three pounds of coke for producing heat in the furnace and smelting the charge. It can be burned and utilized by using a hot blast, not a cold one.

STRAIN is the extension or change of form of a body under the influence of a stretching or distorting force called stress. The ratio of tensile stress per unit cross-section to tensile strain is the modulus or coefficient of elasticity.

CALIFORNIA crude oil makes a good road with almost all kinds of soils, because it contains an asphalt base. On the other hand, Pennsylvania and other oils containing a paraffine base have proven unsatisfactory in road sprinkling.

CYANIDE OF POTASSIUM solutions may be protected from decomposition by the carbonic acid of the air according to the reaction $2KCy + CO_2 = K_2CO_3 + 2HCy$, by covering with heavy petroleum oil and drawing the solution off from the bottom.

APPROXIMATELY, handling earth with pick and shovel would cost about as follows: Excavating and loading in a wagon, 54 cents per cubic yard for hardpan; 27 cents per cubic yard for tough clay; 20 cents per cubic yard for ordinary clay, gravel or loam, and 16 cents per cubic yard for very light sandy soil; this is reckoned on the basis of 20 cents per hour for wages.

THEORETICALLY the horse power necessary to elevate water to a given height, multiply the total weight in pounds of the water discharged per minute by the height in feet, and divide by 33,000; practically this result should be about doubled.

THE Betts process for the treatment of lead bullion is based upon the solubility of lead in an acid solution of lead fluosilicate. The lead is deposited at the cathode, while the gold and silver accumulate in the slimes, and are recovered by ordinary metallurgical methods.

THE use of lime forms the cheapest and least troublesome way for clearing water from a stamp mill so that it can be used over again. This could be done by settling tanks and decantation, or by the use of a settling pond from which the water could be pumped as needed.

NO. 16 wire gauge copper plates are ordinarily used for amalgamating and weigh four pounds per square foot; No. 13 wire gauge, weighing five pounds per square foot, is used for heavy work, and No. 11, weighing six pounds per square foot, is used for mortar plates.

THE failure of the oil burning boiler to supply sufficient steam may be due to the layer of nonconducting soot from black smoke. This can be prevented by thorough combustion obtained by an accurate combination of oil and steam in the atomizer and a proper admission of air.

PLATINUM may be quickly and thoroughly cleaned by rubbing with sodium amalgam applied with a cloth and then putting in water to oxidize the sodium and leave the mercury free to alloy with foreign metals. The platinum is then cleaned and washed with moist sea sand.

IN its application to the generation of electricity the steam turbine is certainly making noticeable progress, and in some cases is displacing the horizontal steam engine for this class of work. Probably the aggregate power of steam turbine sets now in use may be approximately estimated at 200,000 KW.

SLAG-ROASTING galena has been almost abandoned because of excessive volatilization of lead. Desulphurization of zincblende is becoming obsolescent for the same reason. Dust chambers aid in the partial recovery of the volatilized lead, though there is always trouble in condensing and settling lead fume.

TO TEST cyanide solutions for potassium cyanate (KCNO), first convert the KCN into K_2CO_3 by passing CO_2 through the solution and precipitate it with alcohol. The filtered solution contains potassium cyanate if it turns blue upon the addition of cobalt acetate, owing to the formation of cobalt cyanate.

IN assaying zinc ores, preparatory to titration of the zinc solution, the use of aluminum in removing copper is not to be recommended on account of the action of aluminum salts, which are formed on the indicator, and the liability of aluminum to be precipitated as ferrocyanide. Lead should be used in place of aluminum.

IN the case of black powder there might be something in the idea in using the fuse of placing the cap in the middle or the bottom of the charge to occasion a more thorough explosion, but in the case of using dynamite it goes off so quickly that it makes no noticeable difference whether the cap be placed in the bottom, middle or on top.

A SERVICEABLE clinometer may be made by pasting a graduated scale of degrees on a note book cover and suspending a small weight by means of a thread fastened through the center of the arc. The dip of the vein is found by holding the edge of the note book parallel to the vein inclination and noting where the vertical thread cuts the scale.

THE Canyon Ferry, Mont., electrical transmission plant delivers power at Butte, 65 miles distant at 50,000 volts. This is exceeded in volt power and distance of transmission by other systems in Utah and California. As to whether "the limit has been reached" is not possible to answer. The great game of scientific progress is played without a limit.

IT has been found almost impossible to get an air valve-gear which would work satisfactorily at speeds much above fifty revolutions per minute on low-pressure work where the air cylinders are very large, and where the valve area, particularly that of the inlet, must be a very large percentage of the piston area in order to prevent a suction loss in filling the cylinder.

TO make an inch hole in the center of a glass plate, dissolve camphor in turpentine; in this dip the blunted end of a round file; with this file by a slow twisting motion grind a hole in the glass plate, which must rest evenly all around on a perfectly flat surface. Great patience and considerable skill is requisite; when the opening is made through the glass it can be worked to the required size by the file, which must be kept wet all the time of operation by frequent immersion in the camphorated turpentine.

THE difference between mechanical and free hand drawing lies in the point of view. The former represents objects as they are, the point of sight is at an infinite distance and the lines of sight are parallel. In the latter the observer's eye is the point of sight, and the radiating straight lines extending to the different points of the object from the lines of sight. The point of sight may be real or imaginary, the line of sight is imaginary.

IN all overhead construction the electro-static leakage takes the form of a brush discharge between wires with high pressures, and is considerable. One recent test showed loss of energy due to air leakage with 47,300 volts, to be 1215 watts per mile when the distance between the wires was 15 inches. When this distance was increased to 52 inches the leakage was reduced to 122 watts per mile. With high pressures it is usual to place the wires about 10 feet apart.

FEW California mines have a higher altitude than 8000 feet; few Colorado mines are so low. There are "going" mines in that State at an elevation of 13,000 feet. Altman is the highest mining town in the State. "Concentrates" does not know what is "the highest town in the world." Probably Cerro de Pasco, in Peru, is. Its altitude is slightly over 15,000 feet. For 300 years the Cerro de Pasco mine was worked for silver; now it is America's greatest copper mine.

TURQUOISE of a fair quality is found in Pinal county, Ariz. The turquoise was obtained by the ancient inhabitants of that section of the country and worked into articles of personal adornment by them. Turquoise beads and pendants are often found in the ruins in the Gila and Salt River valleys. A genuine turquoise is a gem of slight transparency, sky-blue in color, and is usually found in the veins of rocks composed of gray and yellow quartzite, sandstone, and porphyry dikes.

THERE are several mining papers published on the Pacific coast. In Los Angeles, California, is published the Mining Review; in San Francisco, California, the Mining and Engineering Review; in Grant's Pass, Oregon, the Mining Journal; in Portland, Oregon, the Pacific Miner; in Seattle, Washington, the Northwestern Miner. The different newspapers published in the various mining districts also furnish excellent local accounts of mining progress and development and are of material value therein.

NO coal is mined in Idaho on a large scale. The Boise district, in front of the Boise mountains and between the Boise and Payette rivers, extending north 30 miles from a point 6 miles north of Boise, includes the Horseshoe Bend district, with one 3-foot high-grade lignitic bed, and the Jerusalem district with four beds from 3 to 8 feet thick of lignite. The mines near Salmon City, however, with their 6-foot vein, promise to prove of great importance whenever a railroad supplies them with an outlet.

THE machine drill must have had unfair usage to have broken as stated, for those drills are carefully constructed of tested material. Great care is exerted throughout, and to secure uniform temper the several parts, bolts, nuts, moving pieces are packed in bone ash in a steel box on which a cover is luted, and heated to a bright red in a furnace, whence the several pieces of steel are given a bath in a tank of cold water to give all of them the same degree of hardness, temper and uniformity of texture.

IN the case of Hough vs. Hunt, Supreme Court of Colorado, 70 Pac. Rep., 1079, it was decided that where the locators of a quartz mine after being in possession for several years, and expending $1000 in developing it, suspended work, and during a year did only $25 work on the mine, but hired a man to live in a house on the location and watch the property, the amount paid to him could not be counted to make up the $100 worth of work each year required to conform to the statute concerning preserving the right to the claim.

FINES coming from the extractor boxes 42% in gold and silver often contain no more than 15% to 20% zinc, and of this amount only a small proportion is in the form of metallic zinc; it will be found upon treating it with acid that the hydrogen evolved is small in proportion to the zinc actually in the product, and this is the reason why in acid treating fines one finds it difficult to remove so much of the zinc as he would naturally expect. The zinc is doubtless combined with some organic acid difficult to dissolve in dilute sulphuric acid.

AT the Granby, B. C., smelter the copper matte converting plant comprises a steel building 160x68 feet, containing two horizontal barrel-type converters, 72 inches diameter, 100 inches long. A 40-ton traveling crane handles the shells and matte; a 10-ton traveler brings the molten matte from the furnace building. The blast

pressure is ten pounds per square inch. After sufficient slag is formed it is removed, after which the pure matte is converted into blister copper. The slag is granulated. Each set of converters has a daily capacity of from fifty to seventy tons of matte.

LINSEED OIL is of commercial value solely because of the comparative rapidity with which it absorbs oxygen. To electrical workers a method of arresting the oxidation of a film of linseed oil at any desired point would be of great value. But that seems at present impracticable. It continues to oxidize until it becomes a brittle, cracked and defenseless mass, so far as its capacity to prevent the passage of a stray electric current is concerned. More electrical apparatus has had to be reconstructed or repaired because of the oxidation and other defects of linseed oil than for all other causes combined.

THE California oil holes are not "drilled down into a lake of oil." The oil is in the sand; the hole is drilled down to and through this stratum of oil sand. This stratum may be 1 foot or 100 feet thick. The oil under internal pressure seeps through inch holes in the casing surrounding the perpendicular hole driven through the sand and is pumped to the surface; if there be gas enough the oil will be forced to the top of the well without pumping. About 25% of the sand is oil in a good district. An acre of good area with an oil sand 100 feet thick ought to yield about 150,000 barrels. One well will not ordinarily drain more than an acre of oil land. The local custom is to sink wells 100 feet inside one's boundary.

NATURAL BITUMEN is brownish black in color. In structure it is amorphous. The specific gravity varies from 0.950 to 1.5 or more, according to the mineral matter present. Its melting point varies widely from 180° to 600° F., sometimes only softening and melting with decomposition at over 600° F. It burns with a smoky flame. It varies from the liquid form of maltha through tough and leathery substances to brittle solids. Its value to the maker of compositions for electrical purposes depends on many things, but chiefly on the nature of the pure bitumen, which can be prepared from the natural substance, its melting point, and most of all its capability of being drawn out into threads. Should it possess natural elasticity it is of exceptional value.

GIANT powder will freeze at 42° F.; water at 32°; dynamite when frozen is hard to load and uncertain of effect. Thawing is a simple operation if rightly done, a most dangerous one if carelessly or ignorantly undertaken. Because a stick of giant can be lit with a match and carried while burning in the open air with safety (sometimes) is no reason that it can be thawed before a fire or on top of a stove. If lit with a match there is only a little bit of the mass that is heated, the rest being cold; but if any one starts to roast, bake or fry it, the usual result is disaster, for when the whole stick of giant is exposed to direct heat the entire mass heats up to the danger point very quickly, and at a temperature of 360° F., it is liable to explode. Just how to thaw frozen giant has been stated herein repeatedly. The intent is here to emphasize how not to do it.

THE modus operandi of the filter press process is as follows: Assuming the pulp properly mixed and aerated with the gold partially in solution in weak cyanide previously introduced, it is discharged into the pressure tank or forcing receiver (montejus), where it is first thoroughly agitated to dissolve the gold and then forced by compressed air into the filter press at from fifty to eighty pounds per square inch. When the press is completely filled alternate charges of solution and compressed air are forced through the washing channels of the machines to extract the balance of gold remaining after the preliminary agitation. The final charge of compressed air is continued long enough to dry the cakes after the final displacement of the wash water. The contents of the filter press are then discharged into tip trucks or on conveyor belts by unscrewing the bolts and lifting the frames and plates apart.

A GOOD way to temper the drill is to first heat the bit till cherry red, then plunge into water for a moment, till partly cooled, when it is rubbed on a stone to remove the scales so that the play of colors can be seen in the dark corner of the shop. Between 430° F. and 600° F. these vary from a very pale yellow, through a straw, a brown, a purple and a full blue to a dark blue. If the cooling is uniform the colors should advance parallel to the cutting edge, otherwise that side of the bit on which the colors are moving most rapidly should be held in water. When the colors move parallel with the edge (this is important to insure uniform hardness), watch until it is a straw color and quickly plunge into the water a short distance, moving it about until the steam ceases to form, when it may be left in a quenching bath, usually water, but often brine, tallow or coal tar, which vary the rate of cooling in the order given.

TO MAKE a drift air tight is feasible, though expensive. Some time ago in one of the lower levels in the Moose mine, Raven hill, Cripple Creek, Colo., a drift was run, along the length of which fissures were cut, from which large volumes of gas issued into the workings. The miners worked with difficulty, although the ventilating plant was unusually large. The drift was timbered with square sets and tightly lagged; but the gas made breathing difficult. Then was tried lining the drift from the shaft to the face, 600 feet, top, bottom and sides, with asbestos sheets reinforced with a sheeting of tin plates. This shut off the flow of foul gas. Swelling ground might similarly be held. Ground which swells in mine excavations does not do so rapidly, it often being several days before the swelling becomes troublesome. It is supposed to be partly due to the effect of the contact of the rock with the atmosphere.

HILL'S Ann. Laws, section 3669, provides that material men shall have liens for materials furnished for improvements on land, and that every contractor having charge of the construction of any building or improvement for another shall be held to be the agent of the owner. A contractor constructed a stamp mill and tramway in connection with a mine for defendant, and material men filed liens against the property. In an action to enforce the liens, judgment was given against the defendant for the amount, directing that the mill and tramway be sold to satisfy the judgment, and that any surplus of the proceeds should be paid defendant, with no provision in case of a deficiency. Held, that the defendant could have a personal judgment for the deficiency, notwithstanding the recitals in the judgment of the amounts found to be due. Watson vs. Noonday Min. Co. et al., 60 Pac. Rep., Or., 994.

CODE Civ. Proc. 1895, section 592, authorizes a tenant in common to sue for an injury to the property by a cotenant; and Laws 1899, p. 134, amending the same, declares that nothing contained therein shall prevent the occupancy and enjoyment of mining property by cotenants, or the operation of the same, subject to accounting to a nonjoining co-tenant for net profits, nor prevent such joint co-tenant from receiving his proportionate share of all ores on the dump, on payment or tender of the cost of mining the same. Held, that a cotenant not joining in the operation of a mine, and suing for damages for the removal of ore therefrom through another mine, owned by his tenants in common, to which plaintiff had no right of access, was entitled to an injunction pendente lite to restrain such removal, though defendant offered to account for ore extracted therefrom. Butte & B. Con. Min. Co. vs. Montana Ore Purchasing Co. et al., 60 Pac. Rep., Mont., 1039.

THE discharge which a stream has at a certain height of water is usually found by taking a cross-section at right angles to the direction of the current and multiplying the submerged surface or wetted perimeter of this profile by the mean velocity of the current, according to formula. The section should be taken at a point where the river is of uniform width and of regular form for some distance above and below, so that the directions of the currents may be practically parallel, thus avoiding oblique velocities. As sections of a river bed are quite irregular and would not be the same at points but little separated, it is usually best to take several sections at established intervals, and thus secure a mean cross-section. The stage of water at the commencement of the work, together with changes which take place during its progress, should be known and recorded. When the soundings have been completed, and levels taken for that portion of the river bed which lies above the water at the time of sounding, the whole can be plotted and the area determined for any stage proposed. The points at which soundings are taken along the range line should be accurately located, so that each day's notes may be referred to the same ground.

THE following artificial preparations are of more or less use in compositions or in refining bitumen: Pittsburg flux, produced by heating petroleum oil, such as Pennsylvania residuum, with sulphur. Hydrogen sulphide is given off and the oil becomes tough and sticky, and only melts at a very high temperature. This formation is due to condensation of the unsaturated hydrocarbons by the action of sulphur, the finished product still containing about 4% of sulphur. It will not pull into strings and is very short. Sludge asphalt, made from the sludge tar of the refiners, and is much more like natural bitumen, as it pulls out in threads, melts easily and has the general physical properties of ordinary bitumen. Byerlite, an artificial bitumen of a hard type, produced by the action of oxygen on heavy petroleum oils. No sulphur is employed, and sulphur is not present in the product. Asphaltine, a petroleum residuum specially prepared for the asphalt paving industry, and may be heated for seven hours at 400° F. without losing more than 2% to 5% of volatile oils, while the residue will still continue to flow at ordinary temperatures. Other petroleum or shale oil residuums may lose up to 15%, and the residue will not flow owing to the amount of paraffine present, but in neither case is the resulting residue solid or brittle.

REFINING copper by the copper-bottom process is not a new method; the matte is merely enriched by washing and resmelting till it carries from 55% to 65% copper. This enriched matte is then subjected to a roasting by which occurs a reaction between the oxide and the sulphide, setting free a certain per cent of metallic copper and carrying down much foreign matter, including almost all the gold. It has been recently thought feasible by metallurgists to extend this copper-bottom process to the separation of the gold from the copper. Say ten tons of 65% copper matte are put upon the hearth of a small reverberatory furnace, the doors left open; the charge fired for eight hours; the doors then closed, and the charge melted down. The reaction cited above would set free about 14% copper; the whole charge being tapped into moulds would result in sheets of impure copper—"copper bottoms"—being found beneath the slag blocks nearest the furnaces. At this stage there would be the bulk of the gold concentrated into a ton and a half of material for further treatment, that is returned to the same furnace, roasted again as were the original ten tons, again smelted down, the copper oxide slagged off, and the copper tapped into sheets or granulated for further treatment upon a copper test or other furnace, where it is again roasted, and slagged with silica until sufficiently reduced in quantity to refine the gold with litharge or other suitable flux.

TO quickly determine the amount of sulphur in coke, intimately mix 700 milligrams of finely powdered coke with thirteen grams of sodium peroxide, in a nickel crucible of about 30 c. c. capacity. The peroxide must be finely powdered and dry, and should be weighed rapidly and brushed off the watch glass with a glass brush. The crucible is to be covered and a 3-inch fuse inserted under the edge of the cover and extended well into the mixture. The crucible is then supported on a triangle and placed in about ¾ inch of water; the fuse is ignited and in three or four minutes, when the mass has cooled sufficiently, the crucible and cover are placed in a small beaker and 30 c. c. of water added. The mass dissolves completely in about two minutes. After rinsing off the crucible and cover, the solution is made just acid with hydrochloric acid and filtered through a small filter. The filtrate is boiled and precipitated with barium chloride in the usual way. The fuses are made by nitrating cotton wicking with a mixture of one part fuming nitric acid and two parts concentrated sulphuric acid for twelve hours at 15° C. The nitrated cotton is then washed in running water for twelve hours, to remove every trace of acid, and dried at laboratory temperature. When dry, it is treated with a cold, nearly saturated solution of potassium nitrate for an hour, then the excess of solution is pressed out, dried as before, and finally cut into lengths of 3 inches ready for use.

DRY BATTERIES which have become exhausted can be recharged. Remove the outer cardboard casing from each cell and drill six small holes in the zinc casing about 1 inch from the bottom. As four cells are generally used for ignition purposes in connection with the induction coil, get four small glass or stone jars, about 1 inch larger in diameter than the cells and about three-quarters the height of the same. Dissolve about half an ounce of powdered sal ammoniac in each jar, in a sufficient quantity of water to bring it almost to the top of the jar when the cell is in it. Get four cells of gravity battery and put them in series with each other by connecting the zinc element of one cell to the copper element of another. Put each dry battery cell in the solution in its respective jar and connect the three binding posts on the zincs together, and the three carbon posts also, by means of insulated copper wire. Then attach the wire from the zincs to the zinc element of the gravity batteries, and the wire from the carbons to the copper element of the gravity batteries. Allow the cells to remain over night, and if they are of good, reliable make they will be found in the morning to be almost as good as new. This process of recharging dry batteries can be repeated twice, but after each recharging their renewed life will be shorter than formerly. After the batteries have been recharged the small holes which were drilled in the casing can be stopped by a strip of adhesive tape, covered with bicycle tire cement, and tightly wrapped around the zinc casing over the holes. The cells should be wiped thoroughly dry and then replaced in their cardboard casings when they are ready for use.

THE largest nugget or mass of silver ever mined of which "Concentrates" has authentic detail was a piece weighing 1340 pounds, which was taken from the Smuggler mine, Aspen, Colo., in 1894. In regard to this nugget S. I. Hallet says: "The nugget in question formed part of a consignment of 15,031 pounds of ore, which with silver at 58 cents or thereabouts netted us, free and clear of all expenses, very close to $82,000. This particular nugget was gotten out by itself, and seemed to be extremely pure, so that I photographed it. It was impossible to assay it in the ordinary acceptation of the word, and it was put directly into crucibles and the crucible returns given to us by the company. The smelting charges on such ore were naturally high. This streak of silver occurred as a core in some very rich ore, averaging about 1000 ounces per ton. At times it would be half an inch in thickness, and then widen out to 2 feet or 2½ feet. It was a little purer than a silver dollar and almost as bright. We were obliged to mine by the side of it, allowing it to hang down into the stope until we had reached a natural crack or very thin place, when we could break it off. It extended along the stope for 20 or 30 feet in height, was 3 or 4 feet in length, width as given. As to just how it was made it is hard for me to give a theory. It was sometimes found crystallized in connection with argentite, which might lead one to think that it had simply been argentite, and that by the enormous pressure exerted on it the sulphur had been expelled. Again, I found pieces in which the outer surface was a very thick mass of wire silver practically welded together, which would, of course, account for it in a very different way."

Darien Gold Mines.*

Written for the MINING AND SCIENTIFIC PRESS.

Ever since the time of the early Spanish explorers South and Central America have been looked upon as possible sources of fabulous wealth. But, as has proven true in all other countries, while the mineral may be in the ground, it is not to be taken out without hard and persistent effort. As an example of such effort that has been finally crowned with success, a description of the Espiritu Santo mine of the Darien Gold Mining Co. cannot fail to be of interest. Situated in a densely timbered tropical country among an indolent and often hostile people, difficult of access and inimical to the health of the white man, it is a proposition whose working requires the utmost persistence and courage.

The mine is on the south side of the Cana river, 200 feet above the Cana plateau, which has an elevation of 1800 feet above sea level. Cana is in the province of Darien, and is reached most conveniently from Panama, 80 miles northwest. A steamer runs from Panama down through the Gulf of Darien into Darien harbor, thence up the Rio Tuyra to El Real. At this point freight is transhipped to small light-draught river steamers during the wet season and to native dugout canoes during the dry season. These run 40 miles up the Tuyra to Boca del Cupe at the confluence of the Cupe and Tuyra rivers. From this point, during the dry season, the freight is hauled overland in wagons a distance of 30 miles to the mine,

Maisounabe Shaft from Near Lodin Shaft.

but during the wet season it is taken up the Cupe river 16 miles to Citura station, whence it is packed into the mine, on mules and bulls. An ordinary mule load is 130 pounds and a pack ox can bring up 200 pounds. Most of the machinery at the mine was made for muleback transportation.

The mine had been worked to a depth of 200 feet by Spanish miners working intermittently from 1665 to 1727. These workings followed the soft rich streaks and were mainly shafts irregularly connected by drifts, often timbered and separated by pillars of high-grade ore. These works were finally abandoned because of caves and the intrusion of great quantities of water.

Various unsuccessful attempts were made to clear the mine by pumping, but finally in 1894 the problem was solved by running a 1100-foot adit tunnel which drained the mine to a depth of 150 feet, and made possible the sinking of the Heenan shaft to a depth of 180 feet below the adit level. Considerable rich ore was taken out in the upper levels, but the work was hampered by the number and intricacy of the old workings, the shaft being finally abandoned and filled.

In the meantime in 1898 the Maisounabe shaft was sunk with five compartments, two being 4½x3½ feet, two 4½x3 and one 4½x5. This shaft is 154 feet deep at level No. 1, the adit and drain tunnel, to which the water from the lower levels is pumped by a 4-stage turbine pump direct connected to a hydraulic turbine, placed at the sixth level. The water for power is conducted from the collar of the shaft to the sixth level, 538 feet below, where, after use, it is pumped through the same pipes as the mine water to the drain tunnel. The pump has a capacity of 330 gallons of water per minute. In addition there are auxiliary Cameron pumps operated with compressed air.

Until the new Lodin shaft is completed all hoisting of ore is being done through the Maisounabe shaft. Heretofore, this has been done with an 8x12 double cylinder band friction hoist, but at present a new 14x18 double cylinder, double drum friction hoist is being erected and will soon be ready for use.

The Lodin shaft, started in 1902, is now down to the sixth level. It has three 4x5 compartments and is being sunk on an incline of 70°. During sinking a single drum 8x12 double cylinder, double reduction gear steam hoist is being used. Compressed air is used in pumping. This shaft is to be continued until as deep as the Maisounabe shaft before any ore is hoisted through it. From the Maisounabe shaft levels have been opened up and some stoping done at No. 2, 100 feet below the adit level, at No. 3, 80 feet below, at No. 4, 80 feet deeper, at No. 5, 40 feet below, at No. 6, 84 feet below and at No. 7, 85 feet below.

Quoting Woakes' "Modern Gold Mining in the Darien," Vol. XXIX, Transactions A. I. M. E., "the country rock is essentially andesite in an extremely decomposed state. There are two predominating series of "cleavage planes apparent, the first, generally the most marked, running N. 55° W. with a westerly dip, and the second running N. 65° E. with a southerly dip. Roughly speaking, the ore deposit appears to have been formed in an irregular quadrilateral, the boundaries of which are formed by these cleavage planes, the N. 55° W. cleavages forming the east and west walls, while the N. 65° E. form the north and south walls. In adopting this theory liberal allowance must be made for the variations of bearing, such as naturally would occur in fissures running through such brittle and jointy rock. The sides of the quadrilateral are by no means equal or parallel in their entire length The longer side or base of the figure may be taken as that forming the north wall of the deposit, the shortest is then the opposite or south wall. This gives to the figure the shape of an irregular truncated cone.

"It is, however, the formation and character of the ore body itself which forms the most interesting study to the mineralogist, and is so striking in appearance to the miner. By far the greater part of the ore body is composed of boulders and rock fragments from the adjoining country rock, varying in size from pieces as small as a walnut to masses of many tons weight. They are generally completely angular, but at times as round as a pebble. In the writer's opinion this rounding is not due to the action of the water, but rather to a process of decomposition The rock fragments are completely surrounded by concentric shells of brilliant crystalline sulphides and calcite. The order of deposition of these minerals around the matrix is generally iron-pyrites, then blende, and then galena, with an outer coating of calcite in which occur acicular quartz crystals.

"The gold occurs for the most part in a crystalline form, but often as wires or strings. It is found adhering to the sulphurets, and no doubt the very fine gold is disseminated through them. It is a rule that the greater the percentage of zinc and lead sulphides in the ore, the richer it is in gold. Three distinct classes of ore have been observed in the lode mass. In the vicinity of the walls, especially on the north and west sides of the deposits, the cementing materials of the breccia are chiefly calcite and quartz, while the matrix is softer from more advanced decomposition. Here, therefore, we find low-grade rock. Immediately inside this mass, which varies from 15 to 40 feet wide at different levels, and reckoning from north toward the south we find the interstices in the breccia not entirely filled up with cementing material, an infinity of vugs being left. Here calcite, quartz and iron pyrites, all more or less crystalline, form the cement. This class of gold assays from 1 to 1.5 ounce of gold per ton, according to the amount of the matrix present. To the center and southwest of the lode mass we find the ore very rich in the sulphides of zinc, lead and iron, all more compact, the vugs being entirely absent. This may be said to be the best class of ore in the mine. Occasional pockets and veins of a soft and friable mixture of all the lode-forming constituents are met, containing free gold in quantity. * * * * The conclusion seems to be forced on us that an explosive eruption took place, at a comparatively weak spot, primarily formed by a complicated intersection of a number of fracture planes. The filling up and cementing together of the resultant rock fragments would follow as a natural sequence were the necessary ingredients at hand."

In 1902 a 40-stamp mill was put up, and now treats all the ore from the mine. The ore is very free milling and no attempt is made to concentrate the tailings, as they are of low grade. The ore from above the 180-foot level, the old Spanish workings, gave high values in the concentrates, which were saved by cyaniding. It is thought that this was due to the presence of fine rusty or tarnished gold, which escaped amalgamation rather than to special richness of the sulphurets. This tarnish upon the free gold was probably caused by contact with water impregnated with decomposition products from the timbers and other vegetable matter in the old timbers.

There are 800 men employed about the mine and mill. These are chiefly Jamaican negroes. They are lazy, obstinate and show no interest in their work, working like animals, simply because they are obliged to do so. They constitute 80% of the labor, 10% being natives of the West Indies and 10% natives of Darien. The shift bosses and all in authority are necessarily white men, nearly all being Californians. Construction work on the Panama canal has increased the wages and reduced the efficiency of the labor, as heretofore the supervision of canal work has not been strict, and men, naturally indolent, become more so. The wages range from $1.60 for top labor to $3 for timbermen, being paid in the silver currency of Panama, which is worth 50 cents on the dollar.

The climate is such that white men can not live there more than two or three years without change. There are two seasons—the wet and the dry. From the end of December until the middle of May but little rain falls; but during the balance of the year, especially in June and July and in September and October, the rainfall sometimes totals 100 inches. Henry Loew, a French engineer, is superintendent and manager, and Norris English of California is assistant.

*See Illustrations on Front Page.

Mine Ventilation in Montana.

The Butte, Mont., Miner of the 17th inst. has an extended interview with Benj. Tibbey, former superintendent of the Parrot mine, on his system of supplying fresh air to that mine when in control. Superintendent Tibbey's theory and practice were along the following lines:

The old system used to be to carry the air through every place in one current and take the impure air from one portion of the mine to another, which resulted in its being loaded down with gas so heavily that they could not work on certain days in some parts of the mines. When the weather was stormy or cloudy and the barometer fell there would be a greater discharge of gas, and consequently they would not be able to work more than half time in such weather. The barometer, thermometer, hygrometer and airmeter are as necessary for the mining man as for the sailor. The barometer indicates a change in atmospheric pressure, the thermometer tells the temperature of the air, the hygrometer tests the humidity of the air and the airmeter tells the velocity of the air. If the barometer fall 1 inch it marks a difference in atmospheric pressure of seventy-two pounds to the square foot. In a drift 7 feet high and 4½ feet wide, making an area of 30 square feet, this fall in the barometer shows that there is 2160 pounds less air in that drift, and this condition will remain until the barometer rises again. Approximately the air pressure at the sea level is fifteen pounds to the square inch, 2160 pounds per square foot. It is figured that the pressure diminishes half a pound for every 1000 feet up or down. The atmospheric pressure at 6000 feet is three pounds less than at the sea level,, so the pressure in Butte is 1728 pounds per square foot or one-fifth, which is 432 pounds per square foot less than at the sea level. Less air means less oxygen, requiring one to breathe faster to get the amount of oxygen required. One's average respiration is fourteen to sixteen times a minute, and at each respiration one takes in from 30 to 40 cubic inches of air; 57% of this is exhaled as carbon dioxide. The atmosphere is composed of 21% oxygen and 79% nitrogen, approximately, with a trace of carbonic acid gas. To make a test for carbonic acid gas, take two saucers filled with lime water, and place one on the floor and the other near the ceiling. The one near the floor will turn white, which indicates the presence of the gas, while the one near the ceiling will not change its color. Carbonic acid gas is a third heavier than the air, and consequently always falls; the air will pass through it, like it will through a lady's crepe veil, and it is hard to move.

There is much carbonic acid gas in the mines of Butte. All quartz mines produce carbonic acid gas; coal mines produce the hydrogen gases. Dynamite No. 1 contains 75% nitroglycerine, and one pound of this powder in exploding develops one-third of a pound of carbonic acid gas. The gas created by powder is heated and more mixed with the air immediately after an explosion, and if not given time to settle to the floor, it can be carried away at once, if there is a good circulation of air in the mine. If there is not good ventilation the gas falls to the floor and remains.

This gas also injures the timbers in the mines. Timber rots or decays quicker in a return airway than in an intake. In air return courses is a larger amount of carbonic acid gas and watery vapor than in the intake, and timber, like other vegetable structures, takes up a great amount of carbonic acid gas and watery vapor, and these two ingredients, with the timber, form a chemical action resulting in the rapid decay of the timber. The timber will last many times longer in pure air, and this itself is a vast saving when the cost and the amount of timber used in Butte are considered. The timbers in a downcast shaft will not decay nearly as rapidly as the timbers in an upcast shaft.

In the Parrot mine Superintendent Tibbey divided

the air system up into five different currents from the downcast shaft. Each current had about 4000 feet to travel, about 1500 feet along one level and back through the stopes, and delivered to the upcast and thrown to the elements above for nature to purify. Under his system it required ten minutes for air entering the downcast to be discharged by the upcast to the surface. The air was changed every ten minutes in the mine, as shown by the air-meters, which indicated its exact velocity.

He had a standing reward of $1000 for any man who could find smoke in the face of any working place five minutes after a shot had been fired.

The hygrometer showed the humidity of the air going into the mine and also the increase in humidity of that returning to the surface. If the air showed a humidity of 80% to 85% on leaving the mine, and if the upcast shaft was wet, it indicated the necessity of increasing the air current in the lower levels, for the current was too feeble to raise the heavily laden, moist air. He had five currents in the mine, and the lowest levels were always the wettest. By dividing the air, sometimes he did not have sufficient draught to raise that extra percentage of moisture from the lower levels, which occasionally would result in reversing the current in some levels, and he would have to put in more air to counterbalance this humidity. There were about 200 tons of water carried out of the mine by the air every day. The timbers never bore any fungi. The presence of the fungi indicates carbonic acid gas.

Superintendent Tibbey says that when he took charge of the Parrot he considered well and profited by the mistakes he had seen others make, and he resolved to make the Parrot an example of what good ventilation should be in a mine. He carried the mine workings to the depth of 1100 feet and the air improved with each 100 feet in depth. He thinks he could have carried it to the depth of 1 mile with equally good results. When he left the upcast shaft averaged 60° temperature; the temperature in the face of the workings would not average over 40°, and lower in winter.

His explanation of the cause of heat underground is as follows: The atmosphere is the earth's great boiler valve, preventing the outbreak of gases which are pressed and penned up in the earth's strata like steam in a boiler. The slips and seams of the earth, known to some as crevices in the rocks, are the pores of the earth, the same as the pores of one's hands and body. A fall in the barometer allows these gases to escape owing to the air being lighter. Mines are affected by a change of weather, because the weight of the atmosphere which presses gas in the strata is diminished when the barometer falls. When a change of weather takes place the weight of the atmosphere may be diminished from fifteen to fourteen pounds, figuring at sea level. This diminishing weight of atmosphere causes an extra discharge of gas as an extra discharge of steam would blow out of a boiler if a little weight were taken off the safety valve. The moment the pressure of the atmosphere is reduced, gas expands every place into which it is compressed. Miners often say on seeing a cloudy, wet morning, that they will not be able to work that day. The miner knows the weather affects his working place. The condition of the air in a mine depends much on the state of the air at the surface. The weight of the atmosphere is shown by the height of the barometer. When the barometer has sunk the air has become lighter, and the pressure which before assisted to keep in the gas, now being diminished, allows it to escape. As the gases coming out of the slips and seams of the earth come in contact with air, and the air being hot, the moisture in the mines naturally makes it oppressive, as there is so much humidity in the air, the same as it is in the East. When it is 85° or 90° in the shade, the air being of low humidity, we do not feel the heat here as much as we do in the East. The humidity existing there makes it oppressive, and so it is in the mines when the ceiling is only 7 feet high as in a drift or stope. Compare how much cooler a room with a high ceiling is to one with a low ceiling. Take it in Arizona and Mexico, where it is from 110° to 130° in the shade at times, the atmosphere there contains so little humidity that it is not so oppressive as 90° would be in the East, but if the temperature of Mexico existed in the East with the humidity common there, thousands would die. The powder smoke, the gases of the earth, the carbonic acid gas given off by the men in breathing and perspiring forms a combination of gases. To get rid of it is to remove the cause which produces the effect, and the effect ceases. That can only be done by plenty of fresh air.

The mines in the Lake Superior district are not hot. The reason for their not being so is the ore carries little or no sulphur. The mines of Butte carry 20% more or less. Decomposition of the minerals results in setting up heat. Air expands with heat and contracts with cold. Air at a temperature of 32° weighs 550 grains per cubic foot, and its volume is 100; air at a temperature of 42° weighs 539 grains, and its volume is 102; at 52° its weight is 529 grains, and volume 104; at 62° its weight is 518 grains, and its volume 106; at 72° its weight is 506 grains, and its volume 109; at 82° its weight is 495 grains, and its volume 111; at 92° its weight is 487 grains and its volume 113.

The increase in heat is the greatest ventilating power that there is, if it is properly utilized, for the warm air is so much lighter than the cold air. Like a balloon in the air or a cork in water, the cold air is so much heavier that it rushes down and takes the place of the warm air, forcing the latter out. A current of air is affected by friction, just as water is. Friction increases with velocity. By one system of ventilation you can prevent 80% of the gases from escaping out of the strata of the earth, except as you work the ore out. Under another plan you release these gases of the earth. The extra percentage of gases mixing with the air of a mine increases its volume, thus increasing the friction of the air current, and these gases may become too prevalent, even to the extent, at times, of blocking your ventilating system, and the deeper you go the more poisonous and noxious gases you must expect.

When the Parrot mine only had one downcast and one upcast to a depth of 1100 feet, it was well ventilated. Now there are five shafts more and the temperature is 87°. This increase of raises from each level and shafts to the surface does not show that they improve ventilation, but rather that they have made it worse, as shown by the increase in temperature and the deterioration of the air.

There are too many openings and no man can handle them. Cold will go to heat, but heat is never known to go to cold. The difference in temperature which exists here shows a variation from 80° to 90° in summer to 30° or 40° below zero in winter, and it will be noticed that under these conditions some shafts are downcast in summer and upcast in winter, and the air goes at will and is not conducted as one would water. Air is elastic and can be taken anywhere as long as the laws of nature are obeyed; you cannot drive hot air down and cold air up.

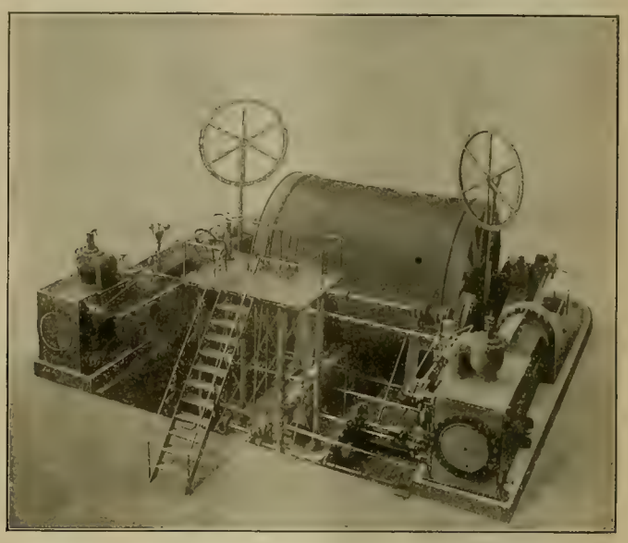
Poor ventilation costs Butte millions of dollars. Say there are 5000 men working in poorly ventilated mines in Butte. One-third of eight hours' pay is $1.17; let us put it at $1 a day for 5000 men. In thirty days that would be $150,000, or $1,800,000 per year—6% on $30,000,000. This is a loss that is no benefit to the working man, no benefit to the companies, but a loss of that amount of money to the world.

Copper Queen Smelter.

Herewith is illustrated a portion of the new Copper Queen smelter at Globe, Ariz. The Copper Queen Co. is locally stated to be the largest producer of copper in the United States. It certainly is one of the foremost factors in the production of this important metal at the present time. The Copper Queen Co. is putting in additional furnaces and converters, and enlarging the power house in connection with an increase of the output. For the use of the engraving acknowledgment is due to the courtesy of the Humphries Photo Co., El Paso, Texas.

New Hoist for Centennial Copper Co.

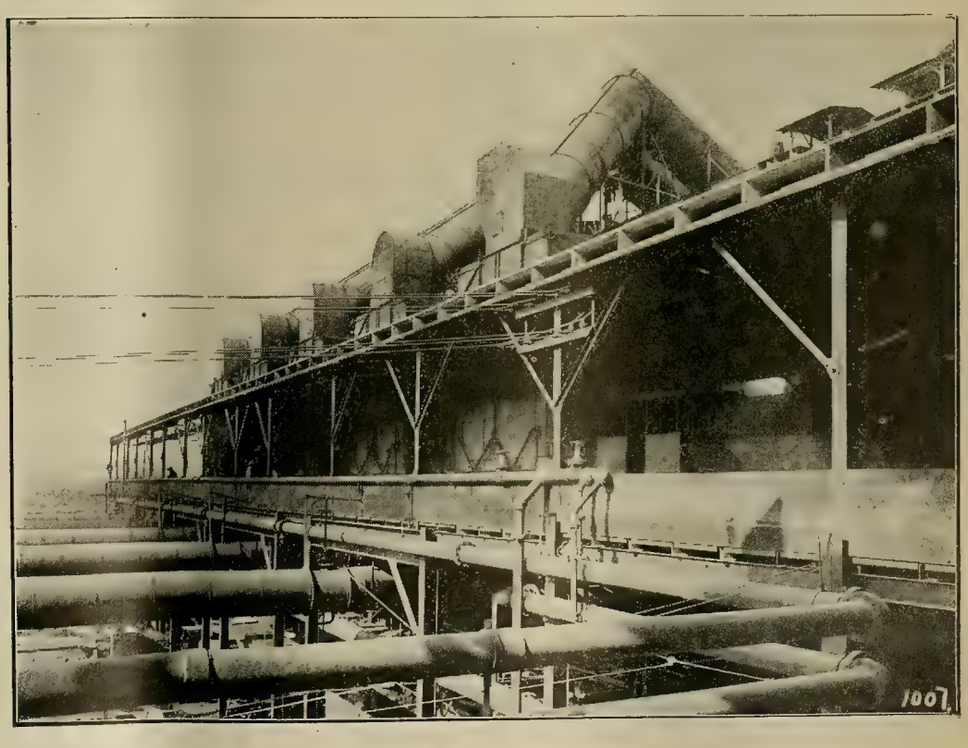
Herewith is illustrated a hoisting engine of heavy design, shipped to the Centennial Copper Co. from the Chicago works of the Sullivan Machinery Co. It is of the direct-acting type and consists of two 36x60-inch simple, reversible Corliss engines of the heavy duty type, connected to a straight-faced drum, 15 feet in diameter by 15 feet winding face. The drum is grooved for 1⅛-inch wire rope and is keyed direct to the engine shaft. The plant is designed to hoist from a vertical depth of 5000 feet at the rate of 4000 feet per minute, with a boiler pressure of 150 pounds. The reverse engine may be operated by either steam or air.



Hoist for Centennial Copper Co.

The brake mechanism is arranged for steam, hand or gravity operation, with independent control in each case. The main throttles are on the cylinders, moved by hand from the engineer's platform, which is elevated to a point higher than the drum. The dial indicators are provided with fast and slow-moving pointers. A sensitive automatic stop and throttle-closing device diminishes the danger of overwinding, with the high speed used.

A QUARTZITE is a sandstone silicified by underground waters. It can be distinguished from vein quartz precipitated from underground waters with a microscope, which will usually show the faint outlines of the original grains of sand.



Copper Queen Smelter, Globe, Arizona.

a. By "spot" value is meant value at the point of production.
b. Long tons are tons of 2,240 avoirdupois pounds; short tons are tons of 2,000 avoirdupois pounds.
c. Production of iron ore. 1885: 15,937,614 long tons; value at mines: $18,219,684. 1896: 10,009,449 long tons, value at mines: $22,789,069. 1897: 17,518,046 long tons; value at mines: $18,053,221. 1898: 19,433,716 long tons; value at mines: $24,999,077. 1900: 27,653,161 long tons, value at mines: $56,680,804. 1901: 28,887,479 long tons, value at mines: $49,256,545. 1902: 35,654,135 long tons; value at mines: $65,412,869. 1903: 35,019,308 long tons, value at mines: $66,328,415. 1904: 27,644,330 long tons; value at mines: $43,186,741.
d. Figures of production furnished by the Bureau of the Mint, Treasury Department. Coining value, $1.2929 per troy ounce. Commercial value 1880: $36,445,000. 1896: $39,055,000. 1897: $32,316,000. 1898: $32,119,420. 1899: $32,858,700. 1900: $35,741,160. 1901: $33,128,400. 1902: $30,415,000. 1903: $29,329,000. 1904: $30,992,534.
e. Figures of production furnished by the Bureau of the Mint, Treasury Department. Coining value, $20.6718 per troy ounce.
f. Including copper made from imported pyrites.
g. The product from domestic ores only.
h. Of 76½ avoirdupois pounds net; of 75 avoirdupois pounds net after June, 1904.
i. Consumption in 1904.
j. Includes antimony smelted from imported ores and antimony contained in hard lead.
k. Including nickel in copper-nickel alloy, and in exported ore and matte.
l. No metallic tin; about 20 short tons of high-grade concentrates shipped to England from South Carolina in 1903. In 1904: about 150 short tons of concentrates from South Carolina, South Dakota, and Alaska shipped to England.
m. Not including $6,000 worth of platinum reported as contained in slimes from copper ore from the Rambler mine, Wyoming.
n. Including brown coal and lignite, and anthracite mined elsewhere than in Pennsylvania. Coke, 1902: 23,401,720 short tons; value at ovens $63,339,167. 1903: 25,274,281 short tons; value at ovens $66,498,664. 1904: 23,621,520 short tons; value at ovens: $66,026,183.
o. Of 42 gallons.
p. Of 300 pounds for natural cement, and 400 pounds for Portland cement.
q. Including limestone for iron flux, but not including grindstones.
r. Included under pyrite in 1901, 1902, 1903, and 1904.
s. Of 280 pounds net. Value is for net product exclusive of cost of packages.
t. Not including value of 60 short tons of cobalt ore produced in Idaho.
u. Including metallic paint, ocher, umber, venetian red, siennа, ground soapstone, ground slate, and mineral black.
v. Value of clay products in 1880: $65,409,806. 1896: $62,110,408. 1897: $62,359,961. 1898: $74,487,960. 1899: Census returns $85,797,370. 1900: $94,212,345. 1901: $110,211,587. 1902: $122,169,531. 1903: $131,062,421. 1904: $131,923,248. Value of sand-lime brick in 1904: $463,150.
w. Including small quantities of zircon, columbite, and gadolinite.
x. Including nitrate of soda, carbonate of soda, sulphate of soda, and alum clays used by paper manufacturers, and bismuth $314; amorphous, $3,175; tungsten: $184,000; and peat, $4,300.

Crushing Machinery for Mines.

NUMBER II—CONCLUDED.

Written for the MINING AND SCIENTIFIC PRESS.

The problem which often confronts the mine superintendent when equipping a new mine is: What kind of crushing machinery shall be installed? This is a question which prejudice should not be permitted to decide. There is a very great difference in ores and some kinds of ore are crushed more effectively and are better prepared for further treatment by one kind of mill than another. For instance, there are numerous examples of the oxidized croppings of a vein carrying gold which is tarnished by iron oxide, coated with a fine film of silica, or which in some other way is unsuited to ready amalgamation. For such an ore stamps are usually found unsuited, and some form of grinding mill should be chosen.

Which type to choose is for the superintendent to decide by test, or, perhaps, he may be able to go far in this through the advantage of previous experience. Machines of the arrastre type remove the foreign coating from the gold, burnish it and render it more readily susceptible to amalgamation. Of course, if the gold is difficult to amalgamate because of chemical combinations, grinding may have no advantage over other methods, and stamps, rolls or some of the various forms of pulverizers may do equally as well as a grinding mill. The future treatment of the ore must always be an important factor in determining by what means it shall be pulverized, and is as important, if not more so, than rapid crushing at low cost.

Where it is undesirable to make a large percentage of slimes, grinding machines would be inadvisable. The character of the ore must then decide whether stamps or rolls are preferable.

In the case of a free-milling gold ore, in which the only element which may be considered rebellious is a small percentage of auriferous pyrite, and where the tendency to create slimes is not pronounced, stamps would probably be chosen, in the absence of any foreign influence, for stamps have been and are still being employed in crushing a very large part of all the gold ores reduced in the world, whether free-milling or not; but the free-milling quartz gold ore is pre-eminently a stamping ore.

Where the ore is more heavily sulphuretted, carrying galena, pyrite, blende, chalcopyrite, etc., and it is desired to concentrate after crushing, it is doubtful if stamps will in every case produce the most satisfactory results. The principles upon which rolls operate suits that class of crushing machinery to the pulverization of ore for concentration. Rolls crush by direct pressure. They are set to crush to a given size, and therefore the tendency to slime is greatly reduced, as the granules of crushed ore which are small enough to pass between the rolls drop down and are not subjected to further comminution, excepting, possibly, in those types of roll-crushing machines which are provided with devices to return a portion of the coarser particles for re-crushing. In these machines often a considerable portion crushed sufficiently fine fails to pass the screens and is returned with the coarser particles, and thus subjected to a further crushing. Nevertheless, rolls have a tendency to create the minimum quantity of slimes and should be employed in those cases where slimes are particularly objectionable, or where the percentage of sulphides, or, rather, heavy mineral to be concentrated, is above 3%. Where the ore contains metals or minerals which are malleable, such as native copper, or native silver or horn silver, each of which will flatten out when passing rolls set for fine crushing, the product would be difficult to concentrate, for the reason that the flat flakes are unsuited to ready concentration on jigs or other concentrating machines, and the percentage of loss is consequently heavy. Stamps, therefore, are superior to rolls on such ore. Some silver sulphides, though somewhat sectile, do not flatten out like flakes of horn silver, but slime so badly that stamps, though suitably preparing the ore for amalgamation in pans, are undesirable where concentration is to follow. This has led to the belief that silver sulphides, particularly argentite, can not be concentrated; but this is not a fact, as this class of ore is being crushed and successfully concentrated at Virginia City by rotary crushing mills.

The flattening of grains of gold is not particularly objectionable in any type of crushing mill, for the reason that the fineness of crushing is usually determined by a screen, and if the flakes of gold, being flattened, are unable to escape through the meshes of the screen, it will be more readily amalgamated in the battery or pan. All gold ores are not so readily amalgamated; but, without doubt, much unnecessary expense is entailed in the treatment of ores by processes and machines unsuited to the ores, and where simpler processes would not only be less expensive but altogether more satisfactory.

The peculiar physical characteristics of ores must be seriously considered when deciding upon the kind of crushing machinery to employ, for more often this is far more important than the chemical combinations occurring in the ores. Where there is a tendency to produce slimes, either this characteristic should be taken advantage of and machinery introduced which will not only crush the ore but produce in the operation the greatest percentage of slimes at the lowest cost, or the class of machine selected should be that which produces the least slimes.

The ore should be carefully studied and experienced opinions solicited as to the kind of machinery to install, if the superintendent has not had sufficient personal experience. It is very easy to make a mistake at the beginning, but it is almost as easy to avoid such errors by employing competent advisers to aid in reaching the proper determination, and not place orders for machinery without knowledge of its adaptability to the conditions as they actually exist.

As to capacity and size of the plant, this is an entirely different matter; but it may be said that it should be as large as the development of the mine can keep constantly supplied with ore. Undoubtedly the tendency is to over equip mines. Mills are built the demands of which can not be met by the mine. The writer visited a new mine some years since, and, although the shaft was only down 125 feet, an underhand stope was found at the 100-foot level. The inquiry was made: "Why are you stoping underhand here?" The reply was almost pathetic: "Great Scott, man! I have to keep a 100-ton smelter going!" To this the encouraging response, "I can see your finish," seemed to lend little hope to the unhappy superintendent in his desperate situation. The expected happened—the smelter was soon closed down for lack of ore.

Here was an instance where the equipment, though of the proper kind, was premature—a mistake almost as serious as the selection of a class of machinery unsuited to the ore.

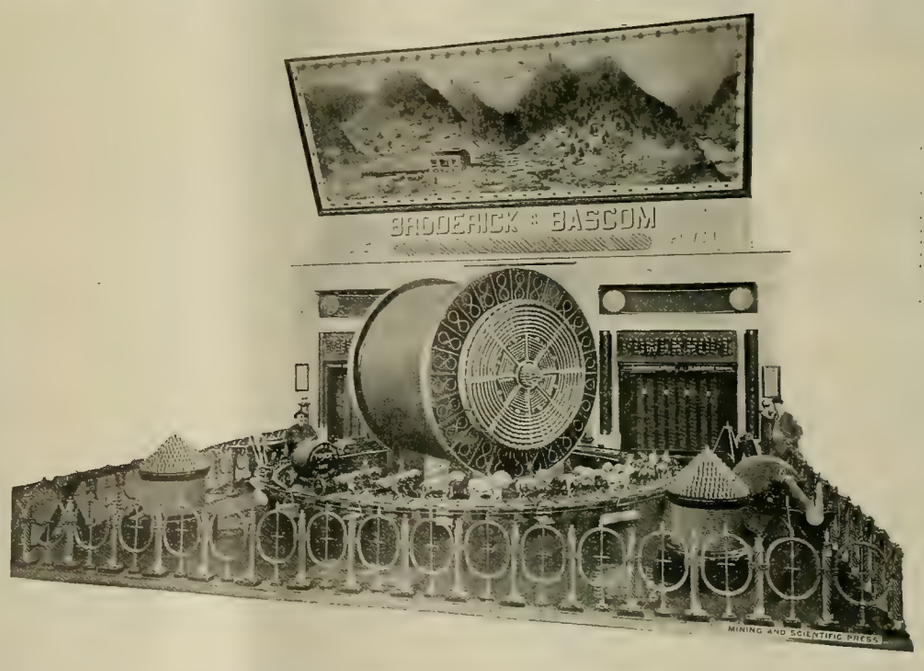
Another important phase of the equipment proposition is the likelihood of the character of the ore changing in depth; but, if the mine be developed far enough ahead, disaster in this direction may be easily averted. In many cases the ores of the oxidized zone are sufficiently abundant to warrant a milling plant in themselves, and modifications or radical changes may be made later suited to the change in the character of the ore.

There appears to be crushing machinery for every class of ore—machines which slime and those which do not, or which, at least, produce a minimum of slimes. It remains for the person or persons in whose hands the decision lies to carefully study the requirements of their ores and to decide along those lines which are proven to produce the most satisfactory economic results.

Wire Rope Exhibit at Portland, Or., Exposition.

That "a thing of beauty is a joy forever" has long been recognized. When such a prosaic thing as wire rope can be transformed into a "thing of beauty" it certainly deserves special mention.

Herewith is portrayed an exhibit now on display in the Liberal Arts Building of the Lewis & Clark Exposition at Portland, Or., and which is an artistic display.



Wire Rope Exhibit at the Portland, Or., Exposition.

The central figure is a spool of cable, 1½ inch diameter, 32,000 feet long, weighing 137,000 pounds, made for the Metropolitan Street Railway of New York. It required fifty-six horses to haul it through the streets. The spool is 10 feet in diameter and 8 feet wide, mounted on a turntable and revolves. On the outside flanges of the spool are two 7-foot diameter revolving disks, containing various sizes and styles of rope. Around the spool is a 20-foot diameter circular track on which is run a miniature spool of cable on a model of the "Jumbo" steel wagon, drawn by thirty miniature horses, all mounted in a complete manner, running in opposite directions to cable and spool. There is also a trainload of wire rope supplies drawn by a miniature locomotive. On the outside of the circular track is a miniature aerial tramway, showing the manner in which ore, timber, etc., are transported in midair. The whole effect is a fine illustration of what is and can be done with wire rope.

In the rear are two cabinet cases containing 5-inch diameter power steel ropes, capable of sustaining 2,500,000 pounds. These ropes revolve and present a handsome appearance.

An interesting feature of the exhibit is the carving set made entirely from power steel rope. The knife is 3 feet long with a perfect rope handle; the fork and steel are in proportion. The set is perfectly made and highly finished in silver.

In the rear and on top of the exhibit is a painting, 30 feet long by 12 feet high, representing a mountain mining aerial tramway scene.

The entire exhibit is from the factory of Broderick & Bascom, St. Louis, Mo., who make wire rope of every design, and for all purposes for which wire rope is adapted and was designed by the company's general superintendent and mechanical engineer, E. P. Frederick.

Placer Mining in Alaska.*

NUMBER VII.

On a 4-foot thickness of pay this amount of fire will thaw, in the time specified, from five to six cubic yards of gravel, at the rate of 9.2 cubic yards to the cord of wood, which is considerably less efficient than the method of thawing with steam. Time, delays and awkwardness of the method, moreover, make wood-fire thawing the most expensive that can be adopted. The figures per foot for shaft sinking range from $3.16 to $7.50 in taking gravel from prospect shafts. The efficiency given in the above-cited case on Deadwood creek appears to be very nearly the same as that given by E. D. Levat for the operations in eastern Siberia.

The direct application of jets of dry steam to the gravel bank through the agency of driven pipes has been found to be the most efficient method in general practice for thawing frozen gravel. The amount of moisture contained in steam can be judged by the color of a jet of steam issuing from a small brass pet cock. If it is transparent or whitish near the orifice it contains less than 2% of moisture; if pure white, the moisture is above 2%.

Fig. 15 shows the details of the steam point and some of the fittings which its use entails.

In creek claims exceeding 15 feet in depth where solidly frozen ground occurs, as, for example, in the new Fairbanks district of Alaska, the method of drifting with the use of the steam point is as follows: A 20 H. P. boiler, capable of running ten steam points, is put on the ground, and frequently one or two extra long points are provided for sinking holes. These long points, from 10 to 12 feet in length, are not so strongly made as the 5-foot points used in the drifting operations. In some cases pieces of ½-inch hydraulic pipe are used. The point is set up on the ground and steam or hot water is turned on. The

*Bulletin 263 U. S. Geological Survey.

time for sinking a hole by this method to bedrock is from twenty-four to forty-eight hours. If large, flat stones are encountered in the gravel underlying the muck it is sometimes advisable to use strong, specially made points to prevent breaking. The average radius of a vertical shaft thus thawed by a single point is 2 feet, and the hole when cleaned out has a cylindrical or tube shape.

If timbering is required after the shaft is sunk it is generally found that the hole will thaw sufficiently to allow the shaft to be carried 4 by 5 feet or 4 by 6 feet inside the timbers. As a rule, however, winter shafts are not timbered. When bedrock is reached a tunnel or runway is run for a distance varying from 50 to 100 feet from the tunnel lengthwise of the claim. From this central drift, which is generally timbered, lateral drifts are run to a distance not exceeding 50 feet, or from this down to 10 feet, or the width of the pay streak. Two tunnels parallel with the central runway are carried at the ends of the cross drifts and connections made from them to the shaft. These are rarely timbered.

The frozen condition of the overburden allows a firm roof to stand without timbering while the gravel is being extracted. This is a great advantage and in part offsets the difficulties attending the breaking up of the frozen ground. The ground is now ready for working. The drifts and main ways are run as low as possible in cases where the pay is thin, but a height of 3½ feet is the lowest that can be worked with economy.

During the night shift sufficient gravel is thawed to occupy the men in extracting it in the day time. In handling, not only the picking and shoveling from the bank must be allowed for, but the wheeling to the shaft, the time of return to the face, and the hoisting of the gravel to the surface and conveying to the dump. The face exposed by the cross drift at the far end of the runway is worked back toward the shaft, and the gravel is trammed in wheelbarrows to the shaft and hoisted. Points 5 feet in length are used to thaw the gravel, and are generally used in batteries and crossheads of four. The points are supplied with steam from a crosshead of iron gas pipe, ¾ inch in diameter, fitted with elbows and short pieces of ½-inch pipe leading to the steam hose, to which the points are attached. The valves are generally set in these short pieces of pipe. The points are driven in with a mallet by the point man working on the night shaft. The points are left in the bank from ten to fourteen hours. The thawing is nearly always done on the night shift, the only men occupied being the point man below and the fireman at the boiler above. Each point thaws a block of gravel on an average 6 feet into the bank, 18 inches on each side of the point and 4 feet high. The crosshead is laid on the floor of the drift, at a distance of 10 feet away from the face, and the steam hose connecting each cock of the crosshead with the individual points must be long enough to reach the desired distance for placing the point in the bank. The cross pipe, to which the hose clamp attaches the hose, should be carried through the steel head and brazed on the opposite side so that it will not break off by a chance blow from the mallet.

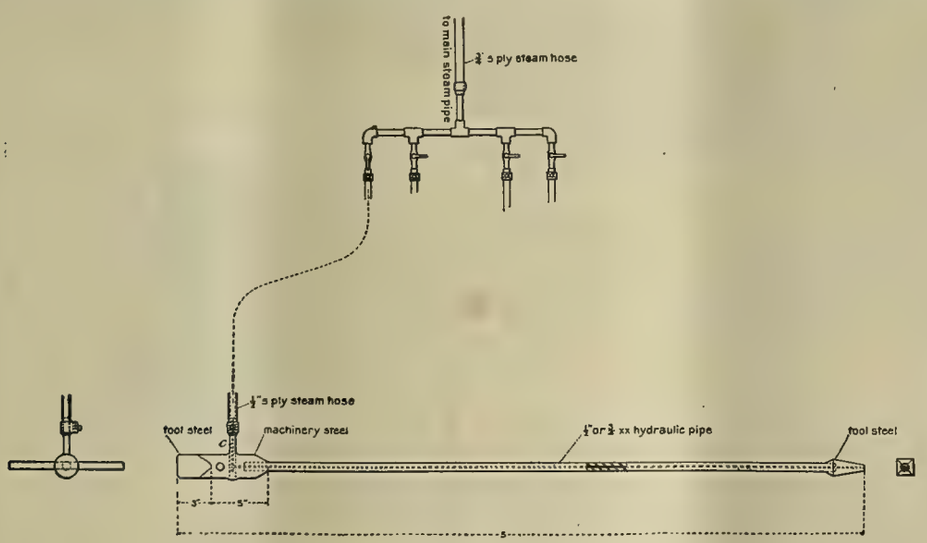


Fig. 15.—Details of Steam Point and Crosshead.

It is considered good practice as a rule to start the points with hot water turned through the hose. The points must be driven carefully and slowly, and for ten points distributed along a face the average time needed is from one to three hours. The amount of steam required for each point has been found to vary in amount from 1 to 2 boiler horsepower. One and one-half may be taken as a safe average. The amount of gravel which a point will thaw appears to vary with the length of the point, and this is regulated somewhat by the character of the gravel. The 5-foot point has been found the most economical size for the small operator.

A typical illustration of the efficiency of the points in the Fairbanks district is the experience at No. 8, below Fairbanks creek. Points of Dawson manufacture, 5 feet long, costing $15 each laid down, were used in crossheads of four. They were put in at distances of from 2 feet 6 inches to 3 feet apart. The points were started with hot water, and it took three hours to drive them in. A 12 H. P. boiler supplied the steam for ten points, three-fourths of a cord of wood being burned on the night shift, when the thawing was done. In twelve hours the ten points thawed a block of gravel 30 feet in length by 5 feet in height by 6 feet into the bank—an average of 3.3 cubic yards to the point.

The above is a little high for the average duty in the Fairbanks district, but is low for the Klondike drifting operations. A typical result on Hunker creek, where 1¼ to 1½ H. P. was used for each 5½-foot point running ten hours, was 4½ cubic yards Three cords of wood, at $13 per cord, were burned in twenty-four hours to generate steam for operating fifteen of these points 10 feet long. These thawed ground 14 feet deep to bedrock. As four cords of wood were burned in addition on the steam shovel, and twenty men, at $6 a day, were employed in the twenty-four hours to get out less than 500 cubic yards a day, the operations were not economical. In connection with a dredging operation the thawing by means of steam conducted through gas pipe in 11-foot lengths was estimated to add 40 cents per yard to the cost of working the ground.

The only drifting and steam thawing plant at Nome gave an efficiency for each point of only 1¼ cubic yard. The points were using in this case a little less than 1 H. P. each and were run only for eight hours. Moreover, the gravel was small and was mixed with much ancient beach sand, which in a frozen condition is extremely difficult to thaw with steam.

The method of thawing with hot water by means of a force pump set in the underground workings, which forces hot water through a small nozzle against the bank, has been tried successfully in the Klondike district. At a claim on Gold Run, where it was desired to extract a 3-foot pay streak of gravel capped by 27 feet of barren gravel at a depth of 50 feet below the surface, a small force pump of the ram pattern, with outside packed valves, was placed in the main runway near the shaft. It drew water from a 6-foot sump near at hand, to which the workings drained. The pump had 4-inch intake, 3-inch discharge choked to 2½-inch, and the water was pumped to the face by means of cotton hose and discharged through a 1-inch brass nozzle at forty pounds pressure. Six thousand gallons of water were used over and over, and by discharging the exhaust from the pump into the suction the water was kept at a temperature of 150° F. In a shift of ten hours the pump, using 30 H. P., thawed and broke down ready for the shovelers 175 cubic yards of gravel. This is vastly superior to the average Klondike duty of the 1½ H. P. steam point, even allowing 4 cubic yards to the point, as the 30 H. P. would supply only twenty points and the maximum duty would be 80 cubic yards

Only under certain very favorable conditions, however, can the hot water method be used. There must be no silt in the gravel, otherwise the water becomes thick and cannot be settled in the sump. If the bedrock is in large flakes, and the pay sinks into it, the hydraulic method is inefficient in thawing the valuable ground. The method is worthy of the serious attention of the Fairbanks placer miners, however, as will be pointed out in the discussion of that district.

(TO BE CONTINUED.)

Compound Condensing Pump.

Herewith is illustrated a compound condensing pump with 200 gallons per minute against 950 feet vertical lift, with no part over 300 pounds in weight. This pump has just been delivered to the Compania Beneficadora Del Concheno, where it is now reported

Compound Condensing Pump.

to be successful operation and doing better than the guarantee. This piece of pump designing was done by the Jeanesville Iron Works, Hazleton, Pa., its builders.

Concerning Forest Fires.

Forest fires are almost always unnecessary. They usually result from failure to realize that carelessness will be followed by injury and distress to others. The resident or traveler in forest regions who takes every precaution not to let fire escape, and who is active in extinguishing fires which he discovers, contributes directly to the development and wealth of the country and to the personal profit and safety of himself and neighbors. He who does not, assumes a great responsibility by endangering not only his own welfare, but that of countless others.

Care with small fires is the best preventive of large ones. The following simple rules may easily be observed by all:

1. Never drop burning matches or tobacco where there is anything to catch fire.
2. Camp fires should be as small as will serve.
3. Fire should not be built in leaves, rotton wood, or other places where it is likely to spread.
4. Fire should not be built against large or hollow logs, where it is difficult to be sure that it is completely out.
5. In windy weather and in dangerous places, camp fires should be confined in holes, or by clearing all vegetable matter from the ground around them.
6. A fire should never be left, even for a short time, before it is completely extinguished.
7. Except as specifically permitted by law for logging redwood or back firing, fire or explosives should not be used to clear land during the dry season without permission from an authorized fire warden.
8. No engines or boilers using fuel other than oil should be operated near forest, brush or grass lands, unless provided with spark arresters and firebox protectors.

The last three of the above rules are law in some States and their infraction directly punishable. Failure to observe the others would be considered willful negligence, should the fire escape and spread.

Any person discovering a fire too large to be put out at once should immediately seek help in the vicinity and, if necessary, notify the nearest fire warden. If no fire warden is available, the local justice of the peace, constable, or road overseer should be called upon. All of these officers are authorized to call upon able-bodied citizens for assistance. Failure upon the part of any person who allows a fire to get beyond his control to take every practicable step to secure assistance is considered willful negligence.

The best tools for fighting fire are the shovel, mattock and ax.

If possible, a fire should be stopped or checked by plowing, trenching, or the use of earth; but if this is impracticable, back firing may be resorted to. The use of back fires is attended by danger of useless burning and loss of control, therefore they should never be set by inexperienced persons except in great emergencies. If a fire warden can be reached in time, such measures should be left to his judgment; if not, and the fire is large, an experienced leader should be chosen to direct the work and his directions followed, so that there may be no loss through unorganized effort.

Back fires should always be set from a road, stream, cleared space, or natural fire line. Since fire rushes up hill, is checked by air currents at the crest, and usually works down hill slowly, it should be attacked from the top of a ridge if possible. If it is burning down hill, endeavor to meet it before it reaches the bottom. If it is working up hill rapidly, it seldom pays to try to stop it before it approaches

the top. The night or early morning hours are the best time to work, when any choice exists, for nearly all forest fires die down more or less at night and spring up during the heat of the day. Never trust a fire which is smoldering or "under control." Continue work until it is out, if possible. If not, watch it closely for fear wind or drying weather will cause it to break out again. Protect valuable timber rather than brush or waste. Young trees suffer more from fire than old ones.

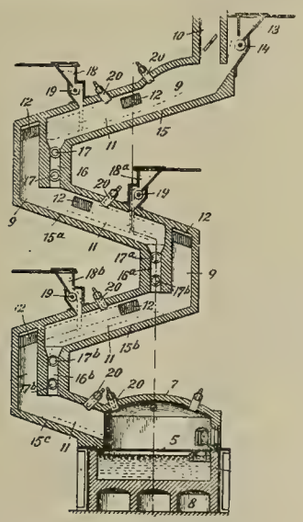
A surface fire in open woods may not seriously injure old growth, but it destroys reproduction by killing the seedlings. Dry sand or earth thrown on a fire is usually as effective as water and easier to get. With a large fire in the vicinity, do not allow yourself and your neighbors to stay at home watching your fences and buildings when organized effort will put the fire out and save not only your property but that of others. Here, more than anywhere else, "In unity there is strength." A little thinking often saves work and makes it successful. Haste and excitement rarely lead to success.

Mining and Metallurgical Patents.

PATENTS ISSUED SEPTEMBER 12, 1905.

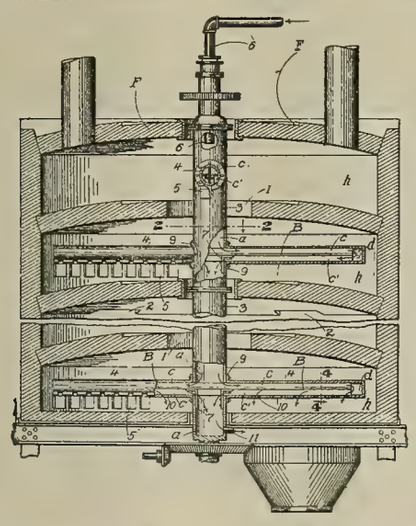
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

METALLURGICAL FURNACE.—No. 798,258; G. H. Benjamin, New York, N. Y.



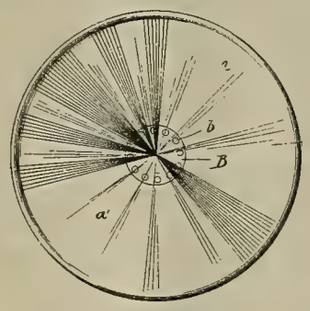
Metallurgical furnace embodying in construction series of oppositely inclined and connected hearths, means for feeding material to be acted on upon uppermost of hearths, means for charging fluxes or other combining materials on surface of material as it passes over each hearth, and means for subjecting material to high temperature as it passes from one hearth to next.

ROASTING FURNACE.—No. 799,063; F. Klepetko, New York.



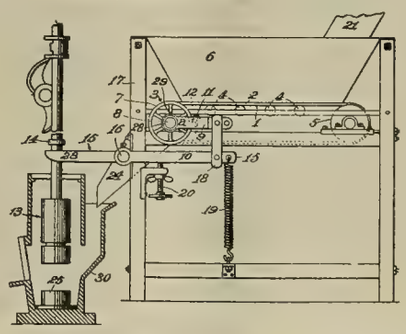
In furnace, hollow rabble shaft, structural members radiating from axis of shaft outwardly through walls thereof, suitable formations conjointly forming, with adjacent portions of members, partition walls dividing shaft into series of contiguous compartments, hollow arms passed over projecting portions of members, forming conduits therewith, arms establishing communication between two consecutive compartments through conduits aforesaid.

MINER'S WASHING PAN.—No. 799,059; J. Johansen, Paramaribo, Dutch Guiana.



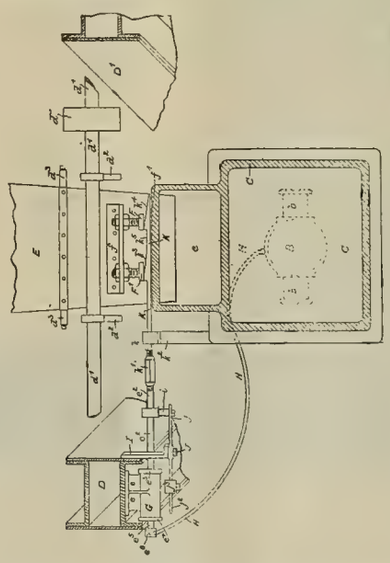
Washing pan for extracting precious metals from foreign substances by manipulation, comprising conical basin of sheet iron, having conical recess in bottom, cup of copper, conforming to and fixed within recess, copper-headed rivets fastening plate therein, inner surfaces of body of basin, plate, and heads of rivets being closely fitted, smoothly polished on common inclined plane, whereby precious metal may be readily caused to move down surface, accumulate on plate, and be there amalgamated.

FEEDER FOR STAMP AND OTHER MILLS.—No. 799,376; C. C. Hamill, Barstow, Cal.



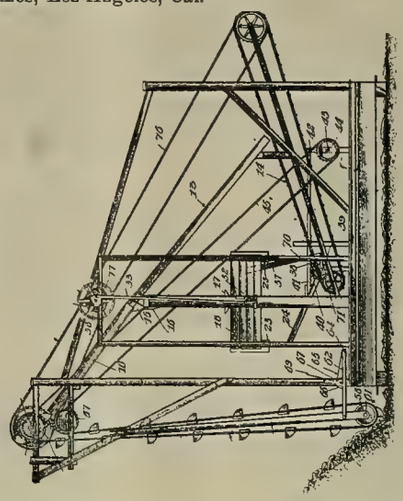
In ore feeder for crushing mills, an open-bottomed hopper, series of rollers beneath bottom thereof, end ones being beyond ends of hopper, each provided with flange at each end, belt on rollers, edges of which belt extend beyond sides of hopper, each edge of belt being flanged portion of surface between flanges being provided with protecting shields, and means for moving belt forward.

ORE-FEEDING MECHANISM OF PNEUMATIC STAMP MILLS.—No. 799,101; J. J. R. Smythe, Johannesburg, South Africa.



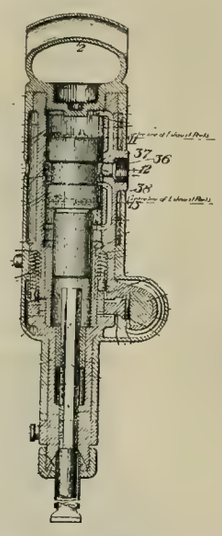
In ore-feeding mechanism for pneumatic stamp mills, combination of cylinder placed in communication with top of pneumatic cylinder, piston working in cylinder operated by excess of pressure in pneumatic cylinder, piston operating means for controlling feed. In combination, stamp stem A, reciprocating pneumatic cylinder B, mortar box C, vibrating feed chute E adapted to deliver ore into feed slot c of mortar box C, means for moving feed chute E in rearward direction, buffers F F′ fixed on under side of feed chute E adapted by impact to deliver ore into mortar box, wedge K formed with inclines k^3 k^4 and flat or plane part k^5 between inclines, bracket k^2 for guiding and supporting wedge K, cylinder G, pipe H placing top of pneumatic cylinder in communication with cylinder G, non-return valve e^6 between cylinders, relief valve e^7, piston e′ and piston rod e^2, means for connecting ends of piston rod e^2 and wedge K, pin or projection i on piston rod e^2, arm j of bell crank lever J formed with slot j′ engaging pin i, arm j^2 of lever J and adjustable weight j^3 arranged thereon.

GOLD SAVING MACHINE.—No. 799,161; J. B. Holmes, Los Angeles, Cal.



In a placer gold separator; a frame; an elevator therein; screening hopper into which elevator empties at upper end of frame; screens in hopper; trough below screens near lower end of hopper; separating boxes below trough; feed hoppers opening into boxes; flexible tubes leading from trough to feed hopper; hackle pins projecting upwardly from bottom of boxes; haggle pins being staggered; riffles extending transversely of boxes; inclined swinging gates above riffles; gangue spouts at ends of boxes; traveling apron below boxes adapted to receive gangue and carry same out of machine; means to cause boxes to reciprocate; means to cause ends of boxes to be alternately raised and depressed.

PNEUMATIC ROCK DRILL.—No. 799,406; A. P. Schmucker, Franklin, Pa.



In portable pneumatically operable drill, combination of cylinder, piston operable therein, second cylinder, piston operable therein, port connecting one end of first-mentioned cylinder with corresponding end of second-mentioned cylinder, port connecting opposite end of first-mentioned cylinder with corresponding opposite end of second-mentioned cylinder, whereby pressure is admitted directly from first-mentioned cylinder to corresponding ends of second-mentioned cylinder, piston in second-mentioned cylinder having rack formed on one side thereof, serrated ring having segment of gear engaging rack, annulus, drill-bit holder provided with ratchet teeth adapted to engage teeth of serrated ring, and teeth of annulus, whereby drill-bit holder is rotated and backward movement thereof prevented, and drill bit seated in holder.

PROCESS OF EXTRACTING GOLD FROM ITS ORES.—No. 799,548; F. W. Dupre, Leopoldshall, Germany.

Process of extracting gold from its ores consisting in subjecting the ores to the dissolving action of aqueous solutions of cyanides in the presence of ethyl alcohols.

MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

Chas. Kirchhoff in a report of the United States Geological Survey on copper production states that there was an increase in the production of copper in the United States of 114,492,750 pounds, from 698,044,517 pounds in 1903 to 812,537,267 pounds in 1904, and an increase in the net exports of 231,638,043 pounds, from 151,614,632 pounds in 1903 to 383,252,675 pounds in 1904. In other words, the enormous export trade absorbed not alone the increase in production, but 117,145,293 pounds additional. The domestic consumption fell off in 1904 as compared with 1903, so that instead of drawing upon stocks to the extent of 117,000,000 pounds they were drawn upon only to the extent of 56,000,000 pounds.

ARIZONA.

Gypsum can be obtained in the Santa Rita mountains, Pima county, southeast of Tucson; the low hills along the San Pedro river in Cochise and Pinal counties; the Sierrita mountains, south of Tucson; the foothills of Santa Catalina mountains, north of Tucson, and the Fort Apache reservation in Navajo county.

Cochise County.

(Special Correspondence).—At the 400-foot level of the shaft of the Tombstone Consolidated mines a large body of carbonate ore showing native silver has been cut. The opening of these ore bodies above the water level shows that the old Contention was not worked out. The old storage plant at the Tombstone has been completed and is in use. An additional station pump has been put in. Since its installation the daily pumping capacity of the plant has been increased from 4,000,000 gallons to 5,500,000 gallons. —— Another rich strike said to have been made in the Tombstone district shows reported values of 4041 ounces in silver, 32 ounces of gold and 5½% lead. The property from which this ore was taken is owned by John Heminger, and adjoins the Independence.

Tombstone, Sept. 24.

(Special Correspondence.)—The new furnace of the Calumet & Arizona Co.'s smelter at Douglas is to be blown in October 7. The new furnace is complete and material for another furnace has been ordered to be built immediately. The smelter is 25 miles from the mine. The first stack was blown in November 15, 1902, the second in the spring of 1903, the third in October, the fourth in 1904, and the fifth just completed. The furnaces are of 300 tons daily capacity each. The fifth furnace will be held in reserve to replace any one of the others out of blast, giving an actual capacity of 1200 tons. Matte is discharged by furnaces into tilting wells and taken thence by electric crane to the four converters, which turn out 99.2% blister copper carrying small gold and silver values.

Douglas, Sept. 25.

(Special Correspondence.)—The flume at the Bonanza Circle mines is taxed to its utmost capacity. The Junction and Briggs shaft of the Calumet & Pittsburg are now discharging, approximately, 4700 gallons a minute. Four pumps, with a capacity of 800 gallons per minute, are now handling the water in the mine, and are lifting 2700 gallons a minute. The flume carries this water to the farm south of the Mule mountains, where the farm company has started a lake. The Hoatson shaft of the Calumet & Pittsburg is down 400 feet and sinking continues. A new boiler is being set and a larger hoist being put in. A larger cement tank for holding oil has been completed and a change house has been finished. A building for framing timber has been added to the surface improvements. The shaft is passing through a stratum of barren limestone.—— At Bisbee drifting has begun in the 800-foot level of the Shattuck-Arizona. Drifting on the 700-foot level will begin again. A new boiler is being set to furnish more power for the pumps, as it is expected the flow of water will increase as development work goes on.——At Dos Cabezos, Collard Bros. have opened up another property near the Gold Nugget which shows a good sized ledge of galena ore. ——The Dos Cabezos G. M. Co. has men taking out nuggets in their placer claims. The recent rains have deposited a large quantity of new gravel in the claims which is showing up good values.

Bisbee, Sept. 25.

(Special Correspondence.)—It has been decided to build the mill of the Arizona M. & D. Co. on the Sonora side of the line for economic reasons. At present a 10-stamp mill will be built. The machinery has been ordered. For the work of excavating for the mill foundations, and the grading of the spur from the railroad to the mines, the contract was awarded to G. McCarty of Naco.

Naco, Sept. 26.

W. K. Maull of the Slimes Tailing Co., who is operating a plant at the Grand Central mill, near Tombstone, states that his company has completed six of the tanks and commenced to handle tailings. Work on the other tanks, twenty in number, is being completed. These tanks are 31 feet in diameter and 7 feet deep and are capable of holding 30,000 gallons of solution. They expect to handle from 200 to 500 tons per day. Cyaniding the entire tailing bed will take some time, as the bed in some places is 15 feet deep.——It is reported from Pearce that the management working the Commonwealth under lease will start the other forty stamps and increase the number of men employed. J. Metcalf is acting as foreman of the mine.

Gila County.

The Payson Milling Co. has built a stamp mill, to work custom ores, 1½ mile below Payson. The mill will be ready for work within a month. On Spring creek, near Payson, P. G. Ellison and Van Duzen & Mankins are developing gold claims and are working the ore in arrastras.——Superintendent W.S. Sultan of the Arizona Commercial C. Co. has made a new contract with the Old Dominion Co. for the treatment of Copper Hill ores and will resume shipment. The sulphide ores will go to the smelter direct and the more siliceous ores to the concentrator. Shipments will be restricted temporarily on account of the lack of bin room at the United Globe where the Copper Hill ores are delivered. ——Near San Carlos the Stanley Butte Co. have finished a wagon road to their property.——Superintendent J. C. Erman of the Live Oak C. Co., near Globe, now has fourteen teams hauling ore.

Graham County.

At the concentrators of the Shannon Copper Co., where acid waters from the mines have played havoc with jig screens, eating up steel wire and punched screens in a few days and wearing out copper and brass screens from abrasion in a month, a new device has been successfully applied. This is said to be so satisfactory that there is no reason why it may not prove excellent in all cases where acid water, containing sulphuric acid and copper sulphate, attacks metal of the mining and dressing plants. The device is a low-voltage electric plant attached to the jig, whereby the screen becomes the cathode to the circuit. This attacks hydrogen and disintegrates it from water, the hydrogen then decomposing the metallic salts in the water and permitting the freed copper to deposit upon that part of the screens formerly reduced by abrasion and destroying the action of the acids upon that part of the screens which it formerly ate out. The system is giving satisfaction.

Mohave County.

At the Gold Road mine at Acme the ore is unbroken from the shaft 550 feet west. In the breast the main ore body is 8 feet wide and samples taken across the entire width gave results of $221 gold to the ton. Eighteen machines are in use. The results obtained at the mill are good, the ore remaining neutral. Leasers are at work in the Billy Bryan mine and are getting out considerable high-grade ore, which is handled through the mill.——Superintendent J. D. Spargo has his machinery put in at the West Gold Road mine at Acme and sinking is going ahead rapidly.——Sinking is progressing rapidly at the Vanderbilt mine, near Cerbat. At the 200 level a crosscut will be driven to the foot wall vein.——F. Dunham of Los Angeles has been examining the Fay mine, south of Kingman. The shaft is down a depth of 165 feet and will be continued to the 200, where levels will be run. A mill may be placed on the property.

Pima County.

The Santa Rita M. Co. at Greaterville is short of water for placer mining, but until recently has done considerable work.——The Robinson-Arizona Co., operating placer mines at Greaterville, is also waiting for water and for the Interior Department at Washington to allow it the privilege to build a reservoir of 3,500,000 gallons' capacity.——Eugene Larrieu and John Plance of Tucson are at Charleston, examining into the feasibility of opening up a vanadium mine at that place. A 12-inch vein is uncovered, and a shipment of the ore will soon be made to New York to test its value.

Santa Cruz County.

(Special Correspondence).—At the Red Rock mine, 13 miles from Patagonia, work has been suspended pending the arrival of a pumping plant to handle the water recently met in the main shaft.

Patagonia, Sept. 25.

Yavapai County.

The Poland mill at Poland is to resume crushing on October 1. It has been repaired and equipped with steam and electric power.——It is reported that Manager C. J. George of the Poland Extension at Poland will start work at both the mine and the mill.——The Arizona Smelting Co. expect to have their 500-ton smelter at Humboldt, formerly Val Verde, completed by December 1. C. E. Finney is manager.——The Davis mine, 15 miles south of Prescott, has been sold to N. O. Murphy, who will start development work.

CALIFORNIA.

The United States Geological Survey's report on copper production for 1904 states that an addition to the future copper production of California will come from the undertaking entered into by the United States M. Co. in Shasta county. The Mammoth mines have been acquired after examination of the property, which indicated that there are in sight 200,000 tons of ore running 5% copper and better. Based upon the development, a smelting plant is now under construction, with an estimated capacity of 1000 tons per day, the smelter being equipped with three stacks, two of which will be in operation at the same time, the third being held in reserve. It is estimated that the copper product will amount to 1,250,000 pounds per month. An English company, the Fresno Copper Co., is building at the mines in Fresno county a works which is to have two furnaces and a converter plant. The plant of the Great Western Gold Co. at Redding was not started in 1904, but will be a contributor to the product of the State during the current year. The Balaklala mine in Shasta county has been purchased by the White Knob Copper Co., which has abandoned its mines at Mackay, Idaho. The smelting plant at the latter property is to be removed to California. The Bully Hill Co., which produces a little over 4,000,000 pounds of copper per annum, has been acquired by interests identical with the General Electric Co.

Amador County.

The Jose Gulch mine at Butte City has started up under the management of W. E. Stewart. A new tunnel has been run 50 feet.

Butte County.

B. C. Clark and E. A. Stent intend working the Yuba mine, in Morris ravine, near Oroville. They have five men developing the property. A shaft is being sunk to below the gravel, then a bedrock tunnel will be run and an upraise to the gold-bearing gravel.

El Dorado County.

Work has been resumed at the North Weber gravel claim, above Camino.——Operations are to be resumed at the Gold & Silver mine, near Kelsey.——The Gopher-Boulder mine, near Kelsey, has been started on a test run.

Kern County.

A 10-stamp mill and cyanide plant is to be put up near Amalie to treat the ore from the Zada, Cowboy and Zenda mines.

Mariposa County.

The Hunt brothers of Bear valley, who have a lease on the Josephine mine, are taking out milling ore, which is crushed at the company's 5-stamp mill at the river.

Mono County.

The Pittsburg claim at Masonic, near Bodie, is being worked by Whietfle & Eastwood under lease.——Work is to be resumed at the Myrtle & Julia, near Masonic. ——Work is to be started on the Blue & Gold, near Masonic, owned by O. R. Morgan of Reno, Nev.

Nevada County.

At Cherokee a hoisting and pumping plant have been put in on the Badger Hill & Cherokee claim, under the superintendency of R. A. Thomas. The shaft is down 40 feet and will be sunk to bedrock.

The South Yuba M. & S. Co. has sold its copper property near French Corral to a company who intend to build a smelter, unless C. M. Wilson makes his proposed road to the property from Lincoln, where he expects to put up a smelter. O. Woehler of Grass Valley is general manager.

Shasta County.

It is reported that the Arps claims at Copper City, 22 miles from Redding, have been sold to T. J. Donnellan. ——Work has been started at the Wiser & Dakin mine, 5 miles northwest of Redding, under the direction of W. C. Stanley, representing F. Van Meter, who intends putting in a new hoist and continuing shaft sinking.—— A new process of reducing ores has been invented by A. B. Moody of Oakland and a plant is being built on the Advance claim, near Delta, on Dog creek, owned principally by H. P. Dalton of Oakland. It is a disintegration process by means of heat and steam.

The White Knob Copper Development Co. of New York is the owner of the Balaklala gold and copper mines, near Kennett, having paid $2,000,000 for them. Rivalry for the possession of these mines has for some time been intense between the White Knob Co. and the Bingham Con., but an amicable settlement was arrived at recently. C. J. McCormick of the White Knob Co. states that it is the intention of the new owners to push development work.

Trinity County.

(Special Correspondence).—The Maple creek hydraulic mine, Junction City mining district on Trinity river, owned in San Francisco, has been a large producer, mainly in coarse gold. It was recently decided to shift the inverted siphon and other machinery to a point at which it was believed the gold output would be increased. This occupied two months. The change was under the direction of Superintendent G. O. Laws, with J. W. Bergin in charge of the siphon work. The pipe is 14 inches in diameter; in its construction Nos. 6, 8, 10 and 12 steel was used. The grade in some instances was at an angle of 38°. Mr. Bergin superintended the riveting of the heavy pipe and shaped all the steel elbows with the hammer, having no rolls to bring to his aid. This siphon passes from the intake down the mountain on a bridge, and at an angle of 38° crosses Maple creek and ascends the opposite slope on a trestle several hundred feet in length and from 3 to 20 feet high, on an angle, to the top of China hill, an ancient gravel deposit, the total length of bridge and trestle being 634 feet. The pressure at the outlet is 426 feet.

The Valdoo M. Co. are making a drill prospect on the Huertevant property in Junction City district, with a view to dredging.

The North Mountain Power Co., with base of operations near Junction City, is sending successfully current to Eureka, Humboldt bay, about 100 miles.

John Tarpley & Co. are fitting up a new mine near the Cie Fse property (owned by the North Mountain Power Co.), opposite Junction City, and will be ready Nov. 1.

The owners of the Dick Mack mine on Summit Creek mountain, in Hay Fork valley, have good gravel in a shaft at a depth of 110 feet. It is blue, and 40 feet of the distance shows a prospect of 40 cents per yard. It is an old mountain channel, and believed to be the most extensive gravel deposit in Trinity county.

Nearly fifty years ago, what were known as the "Kellogg diggings" in upper Hay Fork valley, were among the richest yielding in Trinity county. Recently Beard Bros. opened this old claim and found that the original owner had not reached the bedrock, as supposed, but a stratum of hardpan instead. Beneath this they found a body of blue gravel yielding coarse and fine gold. In one instance a showing of $2.50 per yard was exhibited.

Junction City, Sept. 26.

William Vollmers reports that development work on the Bonanza King mine, near Trinity Center, is progressing satisfactorily. Preparations for the winter are being made. This property, owned by Vollmers, Ellery & Fillman, is under bond to Treadwell Bros. of San Francisco, Joseph Porter superintending the work for the latter. The old wagon road to the mill is being improved. There are 1400 feet of tunnel on the property and a 5-stamp mill.——The ground of the Valdor M. Co. below Junction City is being prospected with a Keystone drill to ascertain its value for dredging purposes. One drill is at work and another is on the way from Trinity Center. H. L. Lowden has charge of the operations for P. Bouery, who is managing the company.

Tuolumne County.

Good progress is reported on the tramway being built from the New Albany mine to the Grizzly mill, near Carters. It is expected the mill will be started up early in October. The old workings of the New Albany are being retimbered.——The Spring Gulch mine, near Tuolumne, owned by R. Marshall of Sonora, has been

bonded to Wm. Connally and J. Vargas, who will begin work on a newly discovered vein running parallel with the Spring Gulch vein.

COLORADO.

(Special Correspondence).—The operators are still having trouble with "high graders" in camps where the ore is high grade, and especially in Cripple Creek district. In that camp there seems to be an organized gang at work in the mines, especially in the mines producing rich ore. In the San Juan considerable high grading is carried on in the richer mines.——The preliminary survey for the drainage tunnel in Cripple Creek is being made by the engineers in order to determine the most feasible route for the tunnel. In order to receive the most benefit from the project it was deemed advisable to appoint an engineer to report after having made surveys and decided upon the best route. A larger portion of the money has already been subscribed by the operators who will receive the benefit.——The electrical men of the State held their third annual session in Glenwood Springs on the 19th. Several interesting papers were read before the meeting.——The laying of the corner stone of the Guggenheim hall will take place Monday, Oct. 2nd, at Golden, Colo., at the School of Mines. The money for this building was donated by S. Guggenheim.——There is considerable opposition being brought to bear against the completion of the Moffat road to Salt Lake. Work is progressing in Gore canyon over which there has been a legal contest between the Reclamation service of the U. S. and the Moffat interests. To date Moffat is the winner.——According to a decision rendered last week at Trinidad in the southern part of the State, the coal miner's union is not liable for damages. Suit was brought against the union by one of the coal companies. The officers, according to the decision, can be sued for damages.

Denver, Sept. 25.

Boulder County.

At Camp Albion, near Boulder, the Cashier M. & M. Co., under the management of T. L. Wood, intends to build a large concentrating mill.

Clear Creek County.

It is reported that the Waldorf M. Co. may sell the Stevens mine and mill for $300,000. Another tunnel, to be 12,000 feet in length, has been started.——Construction work on the Anglo-Saxon mill, near the base of Saxon mountain, near Georgetown, is being carried forward. The walls for the mill building proper are completed. The machinery has been delivered.——George Albertson of Denver, who is driving a tunnel into Republican mountain, near Georgetown, has all the preliminary work completed and will continue the tunnel from the 75-foot point.——A. Roberts has started work on his claims on Democrat mountain, near Georgetown. Development is being done through a crosscut tunnel which has been driven over 200 feet.——I. L. McLyman & Co. are making arrangements to start work on the Royal claims on Columbia mountain, up Beaver creek, near Georgetown. The Royal tunnel is in 400 feet.

Custer County.

Work on the Racine Boy property, near Silver Cliff, owned by Haskell & Townsend, has been resumed as the result of the returns they secured from rock sent to the Salida smelter. The ore yielded 23.8 ounces per ton. The track has been laid through the tunnel.

Gilpin County.

At the Modoc mine on Quartz hill, near Central City, operated by the United Mining & Exploration Co., Superintendent John Lyng reports that they are putting an upraise through from the 250-foot level to get under the ore body and improve the ventilation. It is reported that the company is making arrangements for leasing a mill on North Clear creek to handle their own product, and that they will have the Gilpin tramway lines extended to their mine. Frank Straub of Denver is manager. —— Lyng & Co. of Nevadaville have leased the California dump on Quartz hill and are building a road from the east side of it, and will soon commence shipping to the Hidden Treasure mill on North Clear creek. —— Sinking operations have been started at the Gibson shaft of the Esculapian G. M. Co. in lower Russell district, near Central City, at a depth of 225 feet. W. J. Blake is manager. —— Work is to be started on the Crown Point & Virginia mine at the head of Virginia canyon, near Russell Gulch. —— Sinking has been discontinued at the Pozo mine in Nevada gulch, near Central City, at a depth of 165 feet, and levels are being driven off at 150 feet. The property is being operated under a lease and bond with A. M. Rucker as manager. —— The Goldfield-Homestake M. Co. have been working the Gold Retort mine, near Central City, through the La Crosse tunnel, where an upraise is being made from the tunnel to connect with the shaft workings, which when completed will make the shaft a total depth of 210 feet. A 10x12 friction hoist and boiler are to be put in.

Manager J. R. Anderson of the Gold Dirt mine, near Rollinsville, says that he will pay all pending claims and that the Gold Dirt mill will start up again at full capacity.——The Monarch and Colorado mines mill, in Gambell gulch, near Rollinsville, will probably have five more stamps added to it within a month. This will give the mill ten stamps.

Gunnison County.

(Special Correspondence).—The Mollie Gibson mill at Pitkin is handling 200 tons of silver-lead ore from the Percy La Salle mine.——Newman, Hall & Barnes have a lease on the Little Annie mill, 6 miles from Pitkin, and are handling ore from the Little Annie mine, treating sixty tons per day.——Joe Miller and partners have opened up silver, lead and zinc ore on their property at the head of Taylor park and expect to build a mill to treat the output from the mine.——The Smuggler mine has finally gotten the fire in the mine under control, which necessitated closing down for a time. It is now shipping the usual amount.——The Mineral Farm, near Pitkin, is being worked under lease by E. D. Wright. Electric centrifugal pumps are being put in and as soon as they are ready to operate the shaft will be sunk deeper. It is down 700 feet below the tunnel level. The electric hoist is 2 miles from the mouth of the Cowenhoven tunnel, where it is located.——The hoisting engine of the Homestead is farther in the tunnel. When the pump is put in the company will start breaking ore. This property is operated by the Cowenhoven Co.—— The Bushwhacker is divided into blocks and operated by leasers, and the ore is run through the Hunter creek mill.——The Cowenhoven tunnel is nearly 3 miles in length and cuts Smuggler mountain at a depth of 1400 feet.

Aspen, Sept. 25.

The Keystone lead-silver-zinc mine, near Crested Butte, has been cleaned out and retimbered. An upraise is to be made from the lower level to the surface and a concentrating plant is contemplated.

Lake County.

(Special Correspondence).—In the down town district the Cloud City M. Co., J. A. Jones, superintendent, has secured the Home Extension property, and is sinking the shaft, now down about 600 feet. As soon as the shaft is completed connections will be made with the Cloud City mine, which will give both properties good air. All the water will be pumped from the Cloud City shaft. The distance between the two shafts is 900 feet, of which over 500 feet has already been completed by a drift. As soon as the connections are made a large force will be put on taking out ore.——The Western M. Co., which is operating the Coronado and Penrose, are installing some large pumps to handle the large volume of water which they reached while sinking the Penrose shaft. They intended to sink the shaft to a certain depth and then put in the pumps, as they expected a large flow of water. They were within a few feet of having the shaft completed when they struck a heavy flow, which has caused them much trouble. On account of the ground in the stations at the bottom of the shaft being soft, it became necessary to lay the floors in concrete and set the pumps on concrete foundations. One of the pumps is 18—28x42—10—36, built for 1200 feet, two pumps 18½x36½x10—24, built for 1000 feet. Two of the pumps are set in stations, 16x16x54 feet, and one 14x14 feet. The sump is between the two pumps. The water is now being handled by several smaller pumps, and as soon as the installation is completed the smaller pumps will be withdrawn. About 2000 gallons per minute is being handled in the Penrose shaft and considerable being pumped through the Coronado shaft. A drift connects the two shafts, and all the water will be taken out through the Penrose. It is expected the pumps will be throwing water within a month, and large mining operations will be carried on by this company.——Six boilers, giving 800 H. P., have been put in on the Penrose, and the plant is equipped with a double drum hoist. A steam winch is used in lowering the big pumps into the shaft. The Coronado is producing, through a single compartment shaft, from 180 to 200 tons of lead and copper ores per day.——In Big Evans gulch, 1½ mile from Leadville, A. V. Bohn has the management of the Citizens M. Co., operating the old Mammoth placer. The shaft is down 450 feet, and will be sunk to the 600-foot level. A. V. Bohn also has charge of the Brattleboro.——On Bruce Hill the Penn is being worked in a small way by leasers.——Most of the work done by the Ballard Con. M. & M. Co. on this hill has been in the old workings of the Ballard. C. R. Osgood, the manager, thinks that they are getting out of the caved workings, as the ground is becoming firmer. They are shipping 800 tons per month of $9 ore. Considerable bismuth was among the early shipments.—— There is some complaint here at present on the scarcity of good miners. The card system, it is reported, is being used on some of the properties, regardless of the injunction against the operators in the district from using same. The operators using the card system claim they are using it as individual concerns, and independent of the association. Judge Owers, of the District Court, has the question of a permanent injunction, which was asked for by the Federation, under advisement. Whichever way the decision goes, the question will undoubtedly go to the Supreme Court of the State.

Leadville, Sept. 25.

The Castle View shaft, belonging to the Western M. Co., Carbonate hill, Leadville, has resumed operations and is shipping 100 tons daily of a good grade of iron and sulphides. The iron carries a small percentage of lead, which makes it a desirable product for the smelter.

After being idle for fifteen years, the Grand Trunk claims in the Holy Cross district, near Leadville, has again resumed operations. J. W. Bailey of New York has put men to work.

The Twin Lake Miner says that the Ruby mine has considerable ore blocked out and shipments of high-grade will commence.——Wm. Chisholm has taken out tons of high-grade ore in sinking 12 feet on his vein in Lincoln gulch.——The cave-in in the tunnel of the Twin Lakes G. M. Co. has been caught up and retimbered, and the lessees are ready to develop.——The Echo Canyon G. M. Co. are crosscutting for a vein in the Last Dollar tunnel, and are upraising for the New Discovery vein.——Owing to the hardness of the rock, slow progress is being made in the Mt. Elbert T. & M. tunnel. The Lincoln vein is beginning to improve, but 30 feet more will have to be driven before the rich ore is reached.——Work will be resumed on the Columbine group on Lost Canyon mountain. F. G. Mitchell, the president, is making preparations for the resumption of work.

Mineral County.

Creede has shipped since the beginning of 1905 51,065 tons of ore. The largest output was in March, amounting to 8312 tons, and the lowest in June, 4241 tons. The shipments for July were 5645 tons and for August 5285 tons. There has been a decrease since last year, due to the larger tonnages milled into concentrates. The Creede United Mines Co. sends out 600 tons of concentrates a month. The Del Monte Leasing Co., operating the New York and Chance properties, is marketing from 1500 to 1600 tons per month of crude mineral and the Amethyst from 500 to 600 tons. The Humphreys mill is making two separate products—lead and zinc concentrates, of the latter about 300 tons monthly. The East Willow Creek Milling Co. is producing from 75 to 100 tons of lead concentrates and about the same amount of zinc. The manager expects to have it in running order in the latter part of November. It is of the same style, or nearly so, as the Humphreys. The Commodore is working. There are now plenty of miners to meet the needs of the operators. Men are employed upon the Emma mine at Spar, chiefly on development propositions. The Commodore electric plant has been leased to the Amethyst Co., which will extend the wires to its mine and mill.

Ouray County.

C. L. Ingram is leasing on the Great Western, near Ouray.——The Gypsy group, above the Camp Bird mill, near Ouray, and owned by A. Nelson, has been started up under lease and bond, under the management of C. W. Miller.——The last annual report of the Camp Bird mine for the year from May 1, 1904, to April 30, 1905, shows a profit of £947,252. The development of the mine gave a total of 8568 feet. The most important discovery during the year has been the development of an ore body of considerable size on a vein parallel to that on which work in the western portion of the mine had previously been carried on. Stations have been cut at the fourth and fifth levels, the latter being at a depth of 300 feet below the fourth level. Shaft No. 2 has been enlarged and retimbered, stations being cut at 175 feet and 300 feet below the collar, and sinking resumed after putting in pumping and hoisting machinery. The management, Cox & Hammond, report that after treating 74,674 tons of dry ore, the reserves were on April 30 116,535 tons broken in the stopes and 114,962 tons blocked out, making a total of £31,497 tons of dry ore in reserve. The net profit in the reserves of £993,853 is an increase of £30,738 over the previous year's estimate. From the ore treated during the year an extraction of 93.40% of the gold values has been obtained, yielding $31.18 per ton. Exclusive of depreciation of plant, the total cost of the mine was $9.12 per ton. The additional ten stamps to the mill, with the concentrating and cyaniding plant and electrical hoisting and pumping machines, have been put in.——The Ores & Metals M. Co.'s claims, 3 miles from Ouray, are under the management of J. H. Henler of Cleveland, O. A tunnel has been driven 500 feet in the Ores & Metals vein.

San Juan County.

The new Mogul mill at Gladstone is to be completed by the first of the year. Its capacity will be 200 tons of ore per day. The equipment will consist of forty stamps, Wilfley tables and tube mills for regrinding. The complex character of the ores will make a lead, copper and zinc product, the latter requiring magnetic zinc separators in addition to the regular mill equipment. The Mogul mines are about 1½ mile north of the mill and an aerial tramway will bring the mineral to the plant.

Summit County.

The Carrie mine on Wise mountain, Swan river district, near Breckenridge, is being put in condition for production by S. F. Stoughton, who has a bond and lease. A cyanide plant will probably be added to the 10-stamp mill now in use.——Work has been started on the Gold Dust mine in Illinois gulch, near Breckenridge. E. J. Hoyle is in charge of operations.——The Beaver Creek M. & M. Co. has opened up a pay streak in a drift from the Lucky shaft on Mineral hill, 4 miles east of Breckenridge.——The Carbonate and Little Tommie groups of mines on Mount Baldy is to be worked by the Buckeye G. M. Co., with G. E. Moon of Breckenridge as manager.

Teller County.

The report of J. W. Graham, Jr., secretary of the Jerry Johnson G. M. Co. of Cripple Creek, for the seventeen months ending Aug. 31, 1905, shows that 4953 tons, averaging $47.86 a ton, were shipped during that period. The gross value was $237,457.82, the cost of treatment and other expenses $50,129.27, leaving $187,928.42. The company received in royalties $55,853.41, which, with $6326.01 cash on hand March 31, 1904, $83,459.30 stock sales and other receipts, brings the gross receipts up to $147,674.51. When from this is deducted $83,459.30 for property bought, $24,932.50 for a dividend, and other sums, it left $9715.48 in the treasury Aug. 31, 1905. The main production has come from the 300, 400 and 450-foot levels, no ore of commercial value having been found up to the present time on the lowest level. The 450-foot level is producing nearly all of the ore now being shipped. The shaft on the Caley lease is 440 feet deep, and as it is 75 feet north of the ore being mined by the Gilpin Leasing Co. and on the trend of the ore shoot, it should reach the ore zones very soon.——J. E. Hewitt of Denver and G. Glenn of Cripple Creek, who have a bond and lease on the Pinnacle property, consisting of thirty-six acres on the northeast slope of Bull hill, expect to take up the bond. The shaft on the Lansing claim on this property has been sunk 500 feet.

Stratton's Independence Co., Ltd., of London, Eng., disbursed dividend 17 on Aug. 22. The amount was 12 cents per share, or $120,000. Lessees have been working the mine for some time and to their success are due the profits. The total of dividends to date is about $5,000,000. The company's suit for $6,000,000 against the Stratton estate, on account of alleged salting of the mine, has been dropped.

The Exposition M. & L. Co., in closing a 30-day run on its mill on the Los Angeles mine, on Bull hill, treated 680 tons of ore, having an average value of $6.50 per ton, by cyanide, and the cleanup was $2800. A crusher will be put in capable of handling twenty-five tons an hour. ——The number of employes at the main workings of the Elkton Con. Co. on Raven hill, Cripple Creek, has been increased to ninety. Many of these men are on the 800-foot level, where ore is being broken. Levels lying between 500 and 700 feet are receiving attention. A drift is to be started on a vein found at the 400-foot point when the shaft was being relined.——The Redbird claim of the Nighthawk Co., south of Cripple Creek, is shipping thirty tons daily from the 200-foot level.

The Treasure Vault M. Co. has been organized, with H. M. Lesher as president and general manager, to operate on Bull hill, Cripple Creek.——The Mabel M. mine of the Gold Dollar Co., on the east side of Beacon hill,

Cripple Creek, will resume shipments.——The shaft on the Colorado Boss, near Cripple Creek, has been sunk to the 500-foot level by John Sharpe, lessee, and a crosscut will be run.——C. A. Fitch is running a crosscut from the 900-foot level of the Moon Anchor shaft, near Cripple Creek.——The Index M. & M. Co. are shipping ore from the second and fifth levels of the Mint mine, on Gold hill, near Cripple Creek.

IDAHO.

According to Chas. Kirchhoff in the United States Geological Survey's report on copper production, the copper produced in Idaho during 1904 came entirely from ores shipped to distant smelters, the local works not having been in operation. The plant of the Ladd Metals Co. at Landon will, however, treat ores from the Seven Devils district during the current year.

Blaine County.

Lyttleton Price is running a drift on the 1000-foot level of the Minnie Moore mine, near Hailey.

Elmore County.

H. P. Chattin of Pine states that the Franklin cyanide plant is completed.

KANSAS.

The price of all grades of oil has advanced again. The greatest increase was in the cheaper grades. Fuel oil and oil grading 30° were each advanced 5 cents a barrel. The scale follows: Fuel oil, 35 cents a barrel; 30°, 39 cents; 30½°, 42 cents; 31°, 45 cents; 31½°, 48 cents; 32°, 51 cents. This is the first advance in the price of oil grading 32° since December, 1903.

MICHIGAN.

Houghton County.

The No. 2 or main development shaft on the Rhode Island is down 1265 feet, where the tenth level is established. The upper level at which drifting is being carried forward is the eighth, at a depth of 1000 feet, and has been extended northward 1220 feet from the shaft. The development of the new or No. 3 shaft, north of No. 2, has been begun. Since the No. 3 shaft was started momentous changes have come about in connection with the Kearsarge lode. It has been opened by two new shafts, one at the Tecumseh, 2¼ miles north, and one at the Calumet & Hecla, 3¾ miles from the Rhode Island boundary, while the Tecumseh has a diamond drill at work and will start a shaft within a short time 2 miles north of the boundary, and the Franklin Junior has one drill outfit at work 1500 feet south of the boundary, and a second about 1 mile south of the boundary.

MISSOURI.

Jasper County.

The Consolidated Jack Mines Co. of Duenweg has added a new 14-acre lease of the Crown Point land to their holdings. The shaft on this lease is said to show a 22-foot face, 16 feet high, of 8% jack, with ore in the bottom of both drift and shaft. A new mill will be built at once. Bids are being received by M. W. Hovis at the Joplin office of the company.——The King William mine at Duenweg is on its lower level and taking up stope between the two hoisting shafts. As soon as this work is completed the mill will be put on double shifts. ——The M. & B. mine at Duenweg is being operated at the 200-foot level, where good ore is being worked.

Lawrence County.

The mines at Stotts City have had trouble this summer from water which flows into the shafts at the 30-foot level, where the soft, gravelly ground rests upon hard limestone. Preparations are being made to cement the shafts for the first 30 feet, which will keep all surface water from entering the mines. There is very little water in the lower workings.

MONTANA.

Fergus County.

The members of the Fergus family owning the Fergus tract of 4500 acres adjoining the Bullard property at Kendall have transferred it to the Fergus G. M. Co. of Chicago, in which John A. Drake is the principal owner, the stated price being $2,999,750. The 1500-foot diamond drill that has been in use on the Drake properties at Gilt Edge has been removed to the Fergus tract and boring will commence this week.

The Helena Record states that in the Moccasin mountains of Fergus county the Kendall and Barnes-King companies are working the sedimentary deposits. Some one with an original conception of the ore deposits in Fergus county conceived the idea that many of them were in blanket form. To demonstrate the truth of this idea diamond drills were secured and borings commenced in the valleys in line with the dip of the known paying properties. A number of ranches were bonded for the purpose of prospecting them, and the borings have disclosed immense underlying beds that are declared to be richer than anything as yet discovered on the outcrop of the reefs. There seems to be no doubt but what the ore has been found and penetrated by the drills, and it is now only a question of time when working shafts will be sunk and new and large mills built. The ores are worked by cyaniding. The bedding plane is described as dolomite, or magnesian limestone, seamed here and there with porphyry dikes. The ore is not a quartz, but a fine-grained sediment 60 to 200 feet in width, and is enclosed between dolomite and quartz walls.

Flathead County.

The mill at the Snowshoe mine, near Libby, will begin as soon as the fall rains fill the reservoirs. The mill has been shut down on account of the shortage of water, but the mine has been running.

Granite County.

Paul and Will Scott have started their mill and cyanide plant in Douglas gulch, 1½ mile south of Sunrise, near Phillipsburg. John Huddleston of Phillipsburg is in charge of the mine.——The Gold Coin Co. has decided to erect a 10-stamp mill on their claims below the Milwaukee Gold Extraction Co.'s plant. The Gold Coin mill on Georgetown flats is running and it is reported on better ore than ever before.——The Milwaukee Gold Extraction Co., who are operating the Hannah mines, in the Red Lion district, near Phillipsburg, have started up their new 100-ton mill. The new 3380-foot tramway has been completed. There are twelve towers, set 300 feet apart. The tram buckets have a capacity of 500 pounds each and run 100 feet apart. The mill and other buildings are lighted by electricity, generated at the mill. The mine is operated by means of tunnels and the lead is said to be 60 feet wide. G. H. Savage is general manager and P. C. Waite assistant superintendent.

Madison County.

The High Up mine in Hungry hollow, near Virginia City, is owned by E. W. Merritt, N. D. Johnson and L. L. Callaway. Under the management of E. W. Merritt a tunnel has been run 300 feet to open up the vein. ——The Copperopolis mine, near the High Up, owned by Kelly & Chambers, is shipping ore to the Shafter mill.——The St. John mine, owned by John Reed of Virginia City, is under lease and bond to C. E. Damours. ——The Independence mine, near Virginia City, which is owned by L. L. Callaway and N. D. Johnson, is under lease to Richard Suydenham for two years.

Silver Bow County.

(Special Correspondence).—The North Butte Copper Co. now owns the Speculator, Edith May, Miners Union, Adirondack, Copper Dream, Jessie and Hancock claims, and others that have not yet been made public. At the present rate of production the company has ground opened for five years and is producing at the rate of 3,000,000 pounds of copper a month at a cost of 5½ to 5¾ cents a pound. The company has been operating since last April, but the fact was not given to the public until June, in which month the earnings showed $193,000 net and in July $196,000. Owing to the fact that in August the main shaft was shut down for retimbering and the ore was hoisted through a neighboring mine, by arrangement with the Anaconda Co., it was expected that the earnings would show a decrease, but instead there was an increase of $70,000 over July. When the new shaft is completed the production will be increased 50% and the expense will be lessened.——The Amalgamated Copper Co. is earning at the rate of $5,640,000 a year on its by-products of gold and silver. With an average output of 21,500,000 pounds of copper per month from the company's smelters at Anaconda and Great Falls, its output of by-products is about 800,000 ounces of silver and 300 ounces of gold per month. At the present average price of silver that by-product is worth to the Amalgamated $5,568,000 a year and the gold $72,000.——Owing to the unusually low water in the mountain streams and rivers this year the electric power companies, which have been supplying the Butte mines with power, have been compelled to cut off the supply and the mining companies have returned to the use of steam. The result has been that the big compressors and machines have been put out of commission and smaller ones put in their places. There has been fear that some of the mines would have to suspend operations for a time, but the work will be kept up, though at greater expense and more inconvenience.——The old silver mines in the Butte district contain copper, and on many of them explorations will be made.——The Standard Copper M. & R. Co. has been formed, to develop copper properties in the Fleecer mountains, 25 miles southwest of Butte.——The trouble among the owners of the Southern Cross M. Co., which resulted in a suspension of operations some months ago, is to be adjusted and work will be resumed.——The Jennie Dell M. Co. has been reorganized by the stockholders and work is to be resumed on the mine, in the northwestern part of the Butte district.

Butte, Sept. 25.

NEVADA.

The tungsten deposits in Nevada, according to a recent report of the U. S. Geological Survey, are in the foothills on the west slope of the Snake mountains, near the base of Wheeler peak, and 12 miles south of Osceola. On account, however, of the distance of these deposits from the railroad, the nearest point being Frisco, Utah, on the Oregon Short Line Railway, 100 miles distant, there has been no shipment of ores from these deposits, and most of the work has been the annual assessment work. Recently these deposits have passed into the control of the Tungsten M. & M. Co., which has worked them during the past year. The company has taken out about eighty tons of ore, but has not concentrated any of it. The tungsten mineral is hubnerite and occurs in veins of quartz, which vary from a few inches to a number of feet in width, being normally about 3 feet wide, but pinching in places to a few inches. The main vein or deposit can be traced 2100 feet by means of outcroppings and of float and is composed principally of milky white quartz and hubnerite. The vein, which cuts across the porphyritic granite, is composed of quartz, mica and hornblende, has a strike of N. 68° E., and dips 65° N. W. The hubnerite occurs in solid masses up to 16 and 12 inches in thickness, and also in disseminated particles or blade-like forms through the quartz and occasionally in groups of crystals intermingled with quartz crystals. Occasionally small apophyses of ore are found penetrating out into the country rock. It should be an easy matter to concentrate this ore, as it crushes readily, and the hubnerite could undoubtedly be easily concentrated by jigging.

Lyon County.

The Logan & Holly mine at Como has been sold to the Ohio-Tonopah M. Co., for $75,000.

Nye County.

Big strikes in the Bellhelen district, 65 miles due east of Tonopah, have been made recently. On the Tyree claims a lead was struck said to average $914 to the ton in gold. On the Aggie B claim, belonging to M. Malone, a similar body of ore, carrying surface averages of $214 a ton, was uncovered. Similar strikes were made on the Edwards claims and those of the Southwest Nevada Mines Co. The country has been staked out. Water is found near by.——Superintendent R. M. Smith, of the Bullfrog Mining Co., on Ladd mountain, near Bullfrog, says that they have a vertical depth of 200 feet on vein No. 2, and are employing twelve men.——Work on the Quartette, owned by the Montgomery Quartette Mines Co., on the southern slope of Ladd mountain, will be resumed under the superintendency of A. A. P. Garberg.——The new hoist at the Shoshone is running smoothly and work of shaft sinking is progressing.

Storey County.

The Overland mines at Gold Hill have been sold to T. E. Young of Cleveland, Ohio; P. Ely of Tonopah, manager of the Ohio-Tonopah M. Co., and J. J. McSorley of Calaveras county, Cal., for $25,000. Grading has commenced for a stamp mill and an electric hoist.

OREGON.

Baker County.

The U. S. Geological Survey's report on gypsum produced in 1904 says that beds of rock gypsum of limited extent are found in Oregon on the eastern border of the State, on a ridge dividing Burnt river and Snake river. The rock is used at the 100-ton mill on Burnt river, 4 miles below Huntington, at the station of Lime. The rock is 20 feet thick, is white and crystalline, and is worked by tunnels.

Josephine County.

A rich strike in copper ore is reported from the Queen of Bronze mine, near Takilma, being developed by C. L. Tutt. The Takilma Smelting Co., from July 1 to September 1, shipped thirty-nine cars of matte and used thirty cars of coke besides lime rock.

Owners of placer mines are getting their diggings ready for piping. It has been a long, dry summer and the surface miners have had time to shape their properties for work. Ditches have been cleared and enlarged, new pipe lines laid and flumes rebuilt. Two new hydraulic mines have been developed and equipped during the summer and will begin this winter. All of the old properties will operate again. The Galice Consolidated will have its bedrock flume finished. The Columbia will operate four giants instead of three, and the Royal group of Galice will have three giants at work. The Golden Drift Co., now operating two, will have its power dam enlarged and additional turbines placed so that four giants can be operated.

SOUTH DAKOTA.

Lawrence County.

The Homestake M. Co. of Lead reports for the fiscal year ending May 31, as follows:

	1905.	1904.
Tons of ore milled	1,398,100	1,399,057
Proceeds of bars	$5,221,089	$4,800,558
Other income	81,249	146,877
Total income	$5,302,338	$4,947,435
Operating expenses and taxes	4,235,975	4,039,753
Balance	$1,066,363	$ 907,682
Dividends	819,000	655,200
Balance	$ 247,363	$ 252,482
Interest	16,028	45,014
Surplus	$ 231,335	$ 207,468

The report says that during the past year no mishap to the property of special importance occurred. Developments in various parts of the mine progressed steadily and satisfactorily. The ore at the 1250-foot level has been reached and is being crosscutted. The plant is in fine condition and everything is running smoothly, with ore reserves for years.

The Homestake M. Co. has applied for the purchase of a large amount of timber in the Black Hills forest reservation. The company wishes to purchase and has bid 12,000,000 feet of green timber, 1200 acres of green wood, 3,000,000 feet of timber killed or infested with insects, 3000 acres of wood similarly affected and 5000 acres of dry wood.

UTAH.

The United States Geological Survey's report on copper production states that the principal producers of copper in Utah, all of whom increased their output in 1904, were the United States Mining Co., the Utah Con. and the Bingham. Besides these, the American S. & R. Co. treated a considerable quantity of Utah ores. This company has decided to build a very large copper smelting plant in Salt Lake valley, which will add to the facilities for custom smelting and will stimulate production. The Yampa S. Co. began operations during 1904. The United States M. Co. operates properties in both the Bingham and the Tintic districts, and at its smelting plant also treats custom ores. The mines of the company in the Bingham district are capable of yielding 15,000 short tons of ore per month, while the mines of the Centennial-Eureka group can readily furnish 8500 tons per month. The smelting plant, which consists of six furnaces and two stands of converters, is capable of dealing with 25,000 tons of ore per month. The company has purchased a controlling interest in the De Lamar copper refining plant at Chrome, N. J.

Grand County.

A reduction works may be built near Basin, by the MacDonald Matte Smelter Co. of Toledo, O., who proposes to put in a 60-ton mill. The plant will be a concentrator, working four tons of ore into one, then matte the concentrates on the ground preparatory for shipment. C. W. Munson, president and manager of the MacDonald Co., expects to make the necessary contracts for ore supply and also to arrange for preliminary work on the mill. The properties to be worked this winter are the Grouse Mountain, the Castle Mountain, Skylark, Laura, Tornado, Gold Hill, High Ore, Bryan, Little Dot, Aspen, Corsair and two properties in Beaver basin.

Juab County

It is reported that a concentrating plant is to be put in at the Yankee Con. mill at Park City.——The property, machinery and building of the Martha Washington mine at Silver City have been sold to G. Hanson, C. C. Griggs and J. C. Jensen of Eureka, who intend to

move the hoisting plant to the Copper Jack property in West Tintic.

Salt Lake County.

The Utah Copper Co. has four diamond drills working. Two are in the tunnels and two on the surface. Thirty-three feet in a shift is the drilling record established so far.——The Yampa smelter, at Bingham, is to build a second reverberatory furnace that will bring their capacity to 800 tons per day.

The report of the Consolidated Mercur Gold Mines Co. for the year ending June 30, 1905, shows that the earnings were $100,398.88. During the year the gross earnings were $754,676.91, of which sum $742,291.76 was derived from gold bullion, and the mill at Manning, operated on tailings, gave $13,587.90. The disbursements during the same period amounted to $654,278.03, this leaving a net profit of $100,398.88, the cash on hand and that represented in supplies at the close of the statement amounting to $122,574.75. The report by George H. Dern, treasurer and general manager of the company, shows that during the same period there were reduced 245,026 tons of ore, or an average of 20,419 tons per month. The financial statement shows $728,703.86 in gold produced at the Golden Gate mill during the year. Dividing this amount by the tonnage, as given above, it is found that the extraction averaged $2.97 per ton of ore treated. This shows an improvement of 11 cents per ton as compared with last year's report. The average value of the tailings during the year was confined to 98 cents per ton; that of the previous year to $1.03. However, the months showed fluctuations in the value of the tailings, this due to variations in the composition of the ore. Adding the loss in the tailings to the amount recovered, and the average value of all that was reduced during the year was $3.95 per ton. The mining costs for the year, including prospecting, were $370,934.56, or $1.51 per ton. The milling costs were $273,865.08, or $1.12 per ton. Accordingly, the total operating costs of the company, including all expenses, except construction items, were $644,799.64, or $2.63 per ton. This is the lowest record for expenses that the company has ever made, the best previous report being $2.88 in 1903.

Manager L. A. Jeffs has started a new 200-foot shaft on the Superior property at Alta.

Summit County.

O E. Lawrence is incorporating his lease and bond on the Jupiter claims in Thaynes canyon, near Park City, and will develop them during the coming winter. The shipments reported for the week ending September 23 are: Silver King 1,516,200 pounds, Daly West 1,250,000 pounds, Alliance (jiggings) 178,000 pounds, Clegg & Blake 52,000 pounds, Kearns-Keith 30,000 pounds. Total 3,026,200 pounds.

The Park Record says that the great old Cornish pump, which for many years has lain idle, is being broken up and sold as scrap iron. The massive parts of the pump are being raised by means of large blocks and tackles, placed on trucks and hauled outside and broken up into convenient sizes by means of an apparatus resembling a pile driver. This arrangement is inexpensive. The small pieces are loaded into cars, taken down the shaft and out through the tunnel, to be loaded for shipment to the purchasers. The old Cornish pump was up until the drain tunnel was opened, and it fell into disuse, the finest piece of machinery in the entire Western country. It was placed at the Ontario in 1882-83, to handle the water in the mine. It took more than a year of continual labor to install the pump, while it will be taken out and broken up in about three months. This Cornish pump was exceeded in capacity by Union Consolidated, on the Comstock, Nev., but not equaled in foundations, had a capacity of hoisting 2000 gallons of water per minute from a depth of 2000 feet to the 600 level, where it was run through the tunnel. The bearing shaft and flywheel weighed seventy tons; the pump rod, of Oregon pine 15 inches square, when connected weighed thirty-two tons. The foundation of this engine was excavated on the open hillside, 40 feet deep and laid in solid rock. The pump and foundations cost $300,000.

WASHINGTON.

Snohomish County.

The Imperial mine, near Silverton, is working six men in the lower level. They intend getting compressed air from the Independent concentrator and putting in a machine drill.——The Crown Imperial Co. has run 80 feet of tunnel on its free-milling property, near the head of Malady creek, near Silverton.

Stevens County.

Near Deer Trail, wolframite occurs in the properties of C. S. Palmer of Deer Trail and of the Roselle M. Co., which is mining this mineral at Roselle Camp. The deposits are 27 miles from the railroad. The ore concentrates and will give a product containing about 68% GWO_3.

FOREIGN.

CANADA.

BRITISH COLUMBIA.

Boundary District.

The E. P. U. mine, at Skylark camp, has been closed down to make necessary repairs to the machinery and tramway.——No. 6 furnace at the Granby is ready for operation.——An ore body 10 feet wide is said to have been reached in the new workings in the Emma mine, Summit camp.

The Dominion Tariff Commission from Ottawa, consisting of W. S. Fielding, Minister of Finance; L. P. Brodeur, Minister of Inland Revenue, and W. Patterson, Minister of Customs, were given a memorial by the Granby Consolidated, the British Columbia Copper Co. and the Dominion Copper Co. asking for the following: Removing the duty of 3 cents per pound on explosives; reducing the duty on structural iron from 35% to 20%; removing the duty of 5% on bar steel; reducing the 25% duty on mining candles one-half; reducing the duty on rubber hose from 35% to 20%; reducing the duty on iron pipe from 35% to 25%; removing the duty of 25% on rough and 30% on finished steel castings; removing the duty of $7 per ton on steel rails when used for mining and smelting purposes; placing on the machinery free list blast furnace slag trucks, to be hauled by mechanical power, and admitting free blast furnaces complete and converting machinery complete, also to place repair parts for machinery on the free list; opposing a duty on rough lumber. In most of these cases it was maintained that either the goods were not manufactured at all in Canada, or if they are manufactured, the product is of such poor quality that it is more economical to purchase abroad.

Rossland District.

The memorial presented by the Rossland committee to the government commission on proposed tariff changes recommended a duty on lead and lead products; removal of duty on fluorspar; reduction of duty on explosives when used for mining purposes and removal of duty on raw materials from which they are manufactured; reduction of duty on candles when used for mining purposes and removal of duty on raw materials from which they are manufactured, and the removal of duty on steel rails when used for mining purposes. Regarding the duty to be placed upon lead and the products of lead, they recommend a specific rather than an ad valorem duty, and suggest a rate of 1¼ cent per pound on pig lead and 1½ cent per pound on such products as litharge, dry red lead and orange mineral, as soon as they are manufactured in Canada. While lead is not produced in the Rossland district, the conditions surrounding the production of lead in neighboring districts have a most important bearing upon the mines there, as the dry ores can be treated more cheaply with lead ores, and should the lead mines be obliged to close down the smelters would be unable to provide the lead necessary for the treatment of dry ores, and thereby the cost of smelting the dry ores would be increased.

J. H. Mackenzie of the Le Roi has made arrangements for the shipment of Le Roi ore to Trail. Enough ore will be sent to Northport to keep two furnaces in operation until the reserve ore now on the roast heaps there is smelted. About 5000 tons are now lying in the Northport yards awaiting treatment. The custom ores contracted for by Northport will be smelted there so long as the smelter is in operation, but when it is blown out they will be shipped elsewhere.——The Canadian Smelting Works have built an electrolytic lead refinery at Trail to refine Canadian lead and supply the Canadian market with Canadian pig lead. The most important element in connection with the electrolytic refining process is electrolyte. This has been purchased in the past from manufacturers in the United States, and was formerly subject to a duty of 20%. This duty was removed by the last tariff revision, which helped the industry, but on account of the unstable character of the solution and the great losses experienced in its transportation the Canadian Smelting Works are now contemplating the manufacture of their own hydrofluosilicic acid, or electrolyte, which acid is manufactured by treating fluorspar with sulphuric acid. The sulphuric acid is obtained through Canadian chemical companies, but fluorspar will have to be imported from foreign points, as there is at present no known deposit of fluorspar in the Dominion of Canada. As the electrolyte—which is produced from fluorspar—is an important item in the cost of lead refining, amounting to between 70 cents and $1 per ton of lead, and as fluorspar is at present subject to a duty of 20%, they ask that the duty be removed from fluorspar, so that it will be possible to establish a manufacturing plant for hydrofluoric or hydrofluosilicic acids in Canada. The Rossland Board of Trade asks that the present tariff of 3 cents per pound on explosives when used for mining purposes be reduced by at least one-half, and that the raw materials used in the manufacture thereof be placed upon the free list. The reason for this is that under the present tariff the cost for explosives per ton of ore produced is at least 64 cents, which is an almost impossible burden for the low-grade ores to bear. Mines which are in process of development feel this even to a greater extent, the cost of powder in that case being one-fourth of the total expense thereof. The present duty of 25% ad valorem on the class of candles used for mining purposes adds materially to the expense of mining, inasmuch as 5 cents per ton of ore is added to the cost of mining, and the board urges that the duty on this class of candles be reduced by at least 50%, and in order that the manufacture of candles may be encouraged in Canada the board further urges that the raw materials from which mining candles are manufactured be placed on the free list. The board further urges that rails when used for mining purposes be placed upon the free list, in view of the fact that the raw material is at present receiving a government bounty.

Slocan District.

Two zinc magnetic separators are being put in the Kaslo plant of the Kootenay Ore Co., and another will be added shortly.——Owing to some delay about the vanner blankets, the Rosebery zinc plant is not yet ready for continuous operation.——At the Ottawa mine, on Springer creek near Slocan City, an air compressor is being put in. Sinking will be continued below the lower drifts.

Ontario.

The old Bruce copper mines are to be reopened. A copper smelter is to be built under the supervision of J. J. Case for custom purposes as well as for handling the ores of the Bruce property. The new company to handle the Bruce mine is a London syndicate. The mine is 40 miles east of Sault Ste. Marie, on Georgian bay, Algoma. The smelter will be capable of treating 250 tons of concentrates daily. The concentrating plant at the mine is sufficient, including rock crushers, rolls, hydraulic sizers, tables and vanners.

MEXICO.

Guanajuato.

The San Gregorio mines near Guanajuato, which are owned by the Dwight Furness Co., have been taken over under option by the Mineral Development Co., of which W. M. Wiley of Philadelphia is president. —— The 80-stamp mill of the Guanajuato Reduction & Mines Co. will be ready the first of 1906. The stamp mill is being built near the Cata mine near Guanajuato, and the cyanide plant at the old Flores reduction works. A pipe line 3 miles long will carry the crushed ore from the stamp mill to the cyanide plant.——The Guanajuato Con. M. & M. Co., operating the Sirena mine near Guanajuato, is cyaniding 100 tons of ore daily and the full capacity of the cyanide plant, which is 200 tons a day, will be reached soon. F. C. Corning is president of the company and M. E. McDonald is manager.

Sonora.

It is reported that enough work has been done at the Guadalupe mine of the Pittsburg & Sonora Co., near Bocoachic, to justify putting in a reduction plant. J. P. Casey is manager.——W. R. Holmes of Mexico City has been investigating the ores from the Picacho mine, near Bocoachic, preparatory to putting in a 50-ton reduction plant.——C. F. Hansen, manager of the Monte Vista mine, 15 miles east of Cos on the Nacozari railroad, reports a rich strike of gold ore. He plans to start shipping.

C. E. Perkins of Llano de Oro, who has charge of the engineering work at the mine, says there are 200 men employed. The excavating for the 100-stamp mill is completed. The company is building a road and pipe line 15 miles from Trinchera.——At Cerro Prieto work on the new 120-stamp mill for the Black Mountain M. Co. is under the management of Frank Cox of Nogales.

Personal.

THOS. H. LEGGETT is in New York.

R. L. HERRICK is in Westfield, Mass.

W. A. FARISH has been examining mines at Clifton, Ariz.

W. M. WILEY has left New York to visit Guanajuato, Mexico.

BEN. S. REVETT of Breckenridge, Colo., is in London, England.

ANTON EILERS has left New York for a holiday in Europe.

FRANK K. BORROW is in New York on his return from Rhodesia.

F. W. BRADLEY has returned to San Francisco, Cal., from Alaska.

W. Y. WESTERVELT of Kelvin, Ariz., has been in New York City.

ARTHUR WINSLOW is in San Francisco, Cal., en route to Goldfield, Nev.

W. B. GRAY is superintendent Kawich-Bullfrog mine, near Beatty, Nev.

E. S. WIARD is superintendent Sweeney mill of Federal M. Co. at Kellogg, Idaho.

C. L. DIGNOWITZ has returned to Salt Lake City, Utah, from a trip to Europe.

B. J. MCDONALD is manager Original Bullfrog mine at Bullfrog, Nye county, Nev.

H. H. NICHOLSON has returned to Sumpter, Or., from an extended Eastern trip.

T. A. RICKARD is on his way from New York to Mexico, where he will spend a month.

CHAS. ANDERSON is consulting engineer for the Cowenhoven properties at Aspen, Colo.

J. H. CURLE arrived in New York from London, England, Sept. 27, and will visit California.

D. H. HANKS of Eureka, Utah, has been elected president Signal Peak M. Co. at Richfield, Utah.

W. A. PRICHARD was in New York Sept. 18, on his return from Australia, and will visit California.

W. E. DEFTY, who is now making examinations in Colorado, will be in Sonora, Mexico, in October.

R. MCF. DOBLE of the Abner Doble Co., San Francisco, Cal., has returned from the west coast of Mexico.

C. J. ALLEN has resigned as manager Monumental mine, near Granite, Or., and has returned to Colorado.

D. W. BRUNTON has been selected as consulting engineer for the new drainage tunnel at Cripple Creek, Colo.

GEO. OSWELL has resigned as superintendent Highland mine, near Haines, Or., and has gone to Sumpter, Or.

G. H. CARNAHAN has been appointed superintendent Montezuma Lead Co. at Santa Barbara, Chihuahua, Mex.

F. A. BABCOCK, superintendent Southern M., M. & D. Co., has returned to Silver Plume, Colo., from an Eastern trip.

ARTHUR C. NAHL has succeeded Edgar Richard as superintendent Progreso M. Co. at La Paz, Baja California, Mex.

J. N. A. CONNOR has been appointed metallurgical engineer with Veta Colorado M. & S. Co. at Parral, Chihuahua, Mex.

DANIEL GUGGENHEIM has been elected president American Smelting & Refining Co., succeeding the late E. W. Nash.

J. W. OPP of Jacksonville, Or., has been examining his mines in the Harvey Creek district, near Phillipsburg, Mont.

BARRY HOGARTY has been made assistant superintendent Pueblo, Colo., smelter of A. S. & R. Co., vice James Heggie, resigned.

JNO. C. WAGNER has resigned the general superintendency Thunder Mt. H. Y.-Climax M. Co., Roosevelt, Idaho. J. B. Whitlock succeeds him.

JOHN GOSS has resigned as superintendent Horseshoe mill at Terry, S. D., recently burned, to open offices in the Jackson building, Denver, Colo.

EDGAR RICKARD has resigned as superintendent Progreso M. Co. at La Paz, Baja California, Mex., to engage in private practice in San Francisco, Cal.

J. W. WALKER has been made general manager Arkansas M. & M. Co., working Sound Democrat mines, near Animas Forks, San Juan county, Colo.

H. Y. HADEN, representing the De Laval Steam Turbine Co., Trenton, N. J., is making a trip in the interest of his company through Colorado, California and the Northwest.

R. H. RICHARDS, professor of mining in the Massachusetts Institute of Technology, Boston, is examining for the Dominion Government the magnetic black sand of British Columbia.

THE San Francisco Engineering Club is to be formed in San Francisco, Cal., with a membership of consulting and constructing engineers in the following lines: Chemical, civil, electrical, gas, hydraulic, mechanical, mining and steam. The club is to be formed for the education and fraternalization of its members. The committee on organization is as follows: L. E. Sperry, California Electrical Works; E. B. Parsons, Kilbourne & Clark Co.; T. E. Bibbins, General Electric Co.; C. L. Cory, Union Trust building; A. C. Roulfson, A. C. Roulfson & Co.; George P. Low, Crossley building, and C. E. Wiggin, Electrical Contractors' Association.

Trade Treatises.

Hardsocg Wonder Drill Co. of Ottumwa, Iowa, has issued a neat booklet illustrating and describing various types of the Wonder air hammer rock drills.

Circular 9 C W J of the Crane Co. of Chicago, Ill., gives description and price list of Craneweld flanged pipe joints and Circular 6 C L J Cranelap extra heavy flanged pipe joints.

A folder from Smith, Emery & Co. of 83 New Montgomery street, San Francisco, Cal., details various physical and chemical tests of construction materials, fuels, waters and processes for which they are equipped.

The National Electric Co. of Milwaukee, Wis., describe their Type M. B. generators, direct current and belt driven, in Bulletin 335. The construction and operation of Christensen air brake equipments are discussed in Bulletin 357.

Bulletin 1067, 1068 and 1070 from the Fort Wayne Electric Works of Fort Wayne, Ind., respectively describe their Type A transformers for line service, Type M induction motors for multiphase currents and Series A. C. arc lighting system.

"Charging and Manipulating Apparatus" is the title of a handsomely illustrated book from the Wellman-Seaver-Morgan Co. of Cleveland, Ohio. It contains a series of half-tones and descriptions of various installations for charging open-hearth and reheating furnaces. Its attractive typographical appearance is a favorable introduction to the machinery described.

Books Received.

Water Supply and Irrigation Paper No. 144 of the United States Geological Survey treats on "The Normal Distribution of Chlorine in the Natural Waters of New York and New England," by D. D. Jackson. This is a valuable contribution to the subject of water supply and pollution.

As extracts from "Mineral Resources of the United States for 1904," the United States Geological Survey has issued "Production of Copper," by Chas. Kirchhoff; "Production of Glass and Other Sand," by A. T. Coons; "Production of Gypsum," by G. P. Grimsley, and "Production of Asphaltum and Bituminous Rock," by E. O. Hovey.

The Missouri Bureau of Geology and Mines has issued a report on "The Geology of Moniteau County," by F. B. Van Horn and E. R. Buckley. The book first treats on the physiography, then the historical geology, and finally the economic minerals. These include lead and zinc, barite, coal and various structural materials. This report might well be used as a model by various State mining bureaus in describing their mineral resources.

Commercial Paragraphs.

THE Joshua Hendy Manufacturing Co. of San Francisco, Cal., have moved from their old-time downtown office, 38-44 Fremont street, to their fine new salesrooms directly across the street, 29-81 Fremont street, where they now occupy the entire building, with increased facilities for the transaction of business.

THE Denver Engineering Works Co., Denver, Colo., reports the sale of a complete steam turbine plant to the Denver Union Water Co., to be installed in Platte canyon, near Denver, for pumping water to the city of Denver. The plant is to be completed by Feb. 15, 1906. Same will consist of three steam turbine centrifugal pumps, one steam turbine electric generator, boilers and necessary equipment. The turbines are of the De Laval make.

Obituary.

HENRY GRANT, a pioneer mining man of Garnet, Mont., died September 20 in Deer Lodge at the age of 77 years, from a paralytic stroke.

Latest Market Reports.

SAN FRANCISCO, September 29, 1905.

METALS.

SILVER. — Per oz., Troy: London, 28½d (standard ounce, 925 fine); New York, bar silver, 61⅝c, refined (1000 fine); San Francisco, 61⅝c; Mexican dollars, 47c, San Francisco; 47c, New York.

COPPER.—New York: Standard, $16.25; Lake, $16.00 @16.25; Electrolytic, $16.37½; Casting, $15.75@16.12½. San Francisco: $16.50. Mill copper plates, $17.50; bars, 18@24c. London: £71 spot per ton.

LEAD.—New York, $4.90; St. Louis, $4.75; San Francisco, $5.00, carload lots; 5½c 1000 to 4000 lbs.; pipe 7½c, sheet 8, bar 6½c. London: £14 2s 6d ℔ long ton.

SPELTER.—New York, $6.00: St. Louis, $5.75; London, £27 5s ℔ ton; San Francisco, ton lots, 7c; 100-lb lots, 7¾c.

TIN.—New York, pig, $32.00@32.15; San Francisco, ton lots, 34c; 500 lbs., 35c; 200 lbs., 36c; less, 37½c; bar tin, ℔ lb., 40c. London, £145 12s 6d.

PLATINUM.—San Francisco, crude, $18.50 ℔ oz.; New York, ingot, $20.50 ℔ Troy oz. Platinum ware, 75@$1.00 ℔ gram.

QUICKSILVER.—New York, $40.00@$40.50, large lots; London, £7 2s 6d; San Francisco, local, $38.00@39.00 ℔ flask of 75 lbs.

BABBITT METAL.—San Francisco, No. 1, 10½c; No. 2, 8c; No. 3, 7½c; extra, 17½c; genuine, 32½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 22.00c; San Francisco, Plumbers', 100-lb. lots, 19.15c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb, .04c.

NICKEL.—New York, 55@60c ℔ lb.; ton lots, 40@47c.

ALUMINUM.—No. 1, 99%, small lots, 37c ℔ lb.; 100 lbs.. 35c; 1000 lbs. 34c; ton lots and over, 33c, Pittsburg. No, 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $15.25; gray forge, $14.75; San Francisco, bar, 3½c ℔ lb., 3¾c in small quantities.

STEEL.—Bessemer billets, Pittsburg, $21.00@$24.00; open hearth billets, $23.00@$25.00; San Francisco, bar, 7c to 13c ℔ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 7¾c; less than 500 lbs., per lb., 8c; in 25-lb. tin pails, ½c ℔ lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 7½c; do. in kegs, 8c.

LIME.—Santa Cruz, $1.35 country, $1.25 city ℔ bbl.

CEMENT.—Imported, $3.00@4.00 ℔ bbl.; California, carload lots, $1.80 f. o. b. at works; small lots, $2.10 ℔ bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

LUMBER.—(Retail): Pine, ordinary sizes, $24.00@ 25.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50@5.00; pickets, $21.00;shingles, $2.50 for No. 1, and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00@35.00.

NAILS.—This week the basic prices are: Wire, $2.77; Cut, $3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d, Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4d and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 13½c; Hallett's, 14½c; San Francisco, 1000-lb. lots, 14c; 300@500-lbs. 12c; 100-lb. lots, 13c.

BISMUTH.—Subnitrate, ℔ lb., $2.10.

BONE ASH.—Extra No. 1, 5@6c ℔ lb; No. 1, 4@5c.

BORAX.—Concentrated, 7@8c ℔ lb; powdered, 9@10c; fused, 25@30c; crystal, 7c.

CANDLES.—Spear Brand, 16 oz. adamantine, 40s., 11c ℔ set; 14 oz. adamantine, 40s., 10c; 12 oz. adamantine, 40s, 9c; 10 oz. adamantine, 40s, 8c; 16 oz. stearic, 40s, 12¾c ℔ set; 14 oz. stearic, 40s, 11½; 12 oz. stearic, 40s, 10½c; 10 oz. stearic, 40s, 9½c. 100-case lots and over, ½c less. Not less than 50-case lots, ¼c less. Boxes of 20s, price ½c advance.

CAPS.—3x, $5.50@6 per 1000; 4x, $6.50@7; 5x, $8@8.50; Lion, $9@9.50, in lots not less than 1000.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c ℔ lb.; caustic soda, in drums, 3@3½c ℔ lb.; Cal. s. soda, bbls., $1.10@1.20 ℔ 100 lbs.; sks., 90c@$1.00; chlorate of potash, 12@13c; nitrate of potash, 6¾@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2½@2½c; flour sulphur, French, 2¾@—c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 5¼@5¾c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66° B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

CHROMIUM.—90% and over, ℔ lb., 80c.

COAL.—San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lot, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $8.50, long ton; Colorado Anthracite, $14.00. Coke, $11.50 per ton in bulk, $13.00 in sacks; Sunnyside, $8.50, long ton.

FIRE BRICK.—Domestic, carloads ℔ 1000, f. o. b., factory square, $25.00; soap and split, $22.50; arch and wedge, $27.50; skewback, $30.00; circle, $32.00.

FIRE CLAY.—Domestic, ℔ ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, $8.50.

FUSE.—Triple tape, $4.00 per 1000 feet; double tape, $3.55; single tape, $3.10; Hemp, $2.85; Cement No. 2, $3.10; Cement No. 1, $2.75, in lots of 3000 and up.

OILS.—Linseed, boiled, bbl., 54c; cs., 59c; raw, bbl., 52c; cs., 57c; Lucol oil, boiled, bbl., 51c; cs., 56c; raw-bbl., 49c; cs., 54c. Kerosene—Pearl, per gal., 17½c; Astral, 17½c; Star, 17½c; Extra Star, 20½c; Eocene, 19½c; Elaine, 26c; Water White, in bulk, 11c; Mineral Seal, iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 14½c, do., cs., 21c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 12½c; do., in cs., 19c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 57½c; cs., 62½c; Sperm, crude, 63@68c; Natural White, 68c; Bleached, do., 57c; Whale Oil, cs., 52@67c.

LITHARGE.—Pure, in 25-lb. bags, 9½@10½c ℔ lb.

MAGNESIUM.—Pure, N. Y., $1.60.

MANGANESE.—Black oxide, ℔ lb., 2¾@4c.

MERCURY.—Bichloride, ℔ lb., 77c.

MOLYBDENUM.—Best, $2.75 ℔ lb.

PHOSPHORUS.—American, ℔ lb., 70c.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1**, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2**, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

RED LEAD.—500 lbs. and over at one purchase, ℔ lb. 7½c; less than 500 lbs., 7¾c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 54c

SODIUM.—Metal, ℔ lb., $1.

TUNGSTEN.—Best, ℔ lb., $1.20.

URANIUM.—Oxide, ℔ lb., $3.40.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

OBTUNDING APPARATUS.—No. 799,811. Sept. 19, 1905. Crittenden Van Wyck, San Francisco, Cal. The object of this invention is to provide a simple, practical apparatus which may be placed and held in position on the patient and be and remain entirely independent of the handpiece, which shall be capable of directing a spray in any desired direction and to any part of the mouth, which will maintain the spray continuously as long as necessary or desired, whether the operator is immediately at hand or not, and also which will provide a shield for the patient's nostrils and a spreader and holder for the rubber dam. The apparatus comprises the combination of a plate shaped to rest upon the upper lip of a patient, and having a convexed portion fitting over the nose, said plate having means for the attachment of the rubber dam, an ejector and means for removably supporting the latter on the plate and on either side of the patient's mouth.

TRAVELING ATTACHMENTS FOR BUILDINGS.—No. 799,865. Sept. 19, 1905. Thomas McConnell, San Francisco, Cal. This invention relates to attachments which are especially designed for buildings and for the purpose of saving life and property in case of fires and generally to make access to any part of the building from the front. Its object is to make such access easy and rapid, to assist in the removal of persons or property from the windows at various heights in the building, and to enable the firemen to conveniently apply water at different points, and to obtain easy access to any part of the building front. The apparatus comprises a frame, a track upon which said frame may travel parallel with the upper part of the building, a car suspended from said frame, mechanism by which it may be raised or depressed with relation thereto, means for preventing the swinging of the car, said means comprising horizontally guided slidable bars adapted to project from the ends of the car and contact with the sides of the building and locks for said brace-bars.

STONE SAWS.—No. 799,870. Sept. 19, 1905. William B. Buble, Rio Vista, Cal. This invention relates to improvements in what are known as "granite" or "stone-sawing" machines. Its object is to provide an improvement in the teeth or blades which form the cutting or operating portions of such saw and a means for adjusting and interlocking such blades with the bars or carriers by which they are supported. The invention consists of independent blades having V-shaped channels in the lower edges, bars having vertical channels cut through them to receive the saw-blades, with intermediate integral spacing portions, keys driven in said channels to lock the blades edgewise, and binding-screws adapted to lock the blades transversely.

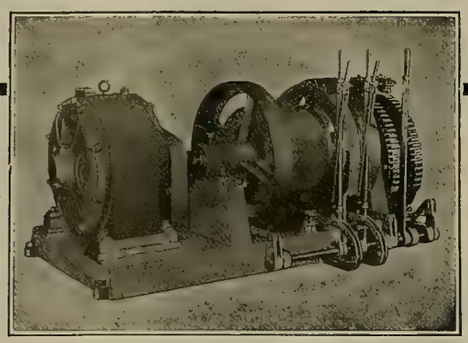
CHECKREIN ATTACHMENT.—No, 799,920. Sept. 19, 1905. Louis Moretti, Santa Cruz, Cal. The object of this invention is to provide a device which when in use holds the checkrein and the horse's head in the desired position. When it is desirable to release the horse from the tension of the checkrein, it may be done by the occupant of the carriage without leaving his seat, and when it is desired to again check up the horse's head it can be done in a similar manner. The device consists of a spring-actuated revoluble drum upon which the checkrein may be coiled, a shaft for the drum, and a means for locking the drum and holding the check in position, said means consisting of a fulcrumed spring-actuated lever having one arm adapted to engage and lock the drum-shaft and the other arm driving reins.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING SEPTEMBER 12, 1905.

799,293.—TIRES J. Baker, Pasadena, Cal.
799,294.—HARNESS—G. V. Beckman, Lodi, Cal.
799,453.—CAR STEP—G. G. Comer, Kalama, Wash.
799,460.—TOBACCO PIPE—A. C. Duncan, Tesla, Cal.
799,044.—SHOE LACING HOOK—H. J. Griswold, Eureka, Cal.
799,376.—ORE FEEDER—C. C. Hamill, Barstow, Cal.
799,335.—BERRY BOX—P. Henrich, Seattle, Wash.
799,161.—GOLD SAVING MACHINE—J. B. Holmes, Los Angeles, Cal.
799, 234.—CARPENTER'S PLANE—J. Jett, San Francisco.
799,341.—GAS GENERATOR—A. W. Jones, Alameda, Cal.
799,167.—PENCIL HOLDER—G. Jorgensen, Seattle, Wash.
799,389.—GRAINING MACHINE—H. G. Krasky, San Francisco.
799,390.—BABY CARRIAGE—M. A. Kuykendall, Portland, Or.
799,181.—SAWMILL DOG—A. B. McCulloch, Everett, Wash.
799,408.—WEEDER—L. L. Bidwell, Rivera, Cal.
799,104.—FLOWER STAND—T. S. Sprague, Alma, Wash.
799,617.—FRUIT CLIPPER—E. P. Steffa, Pomona, Cal.
799,416.—SCREEN—J Stork, San Diego, Cal.
799,426.—STILL—H. B. Williams, McMurray, Wash.



Mine Hoist Driven by Westinghouse Type C Induction Motor.

Westinghouse

Type C Induction Motors For Mine Work

Secure the best, rather than incur the expense of constant repairs.

We invite correspondence.

Mine Accidents—Mine Inspection.

The most casual reader of the daily papers published in the mining towns cannot help noting the number of mine accidents that constantly occur. Whether they can indeed be all called "accidents" is questionable, as many of them are manifestly cases of cause and effect, and not "accidents" in the strict sense of the term. In the course of a recent hour's reading of local papers was observed the following: The death of Henry Jones and Thomas Ball at the Keystone mine, Sierra county, Cal. They were working in an upraise to tap the old workings. They knew that a great body of water was somewhere above or about them, but had no exact memoranda as to its precise locality. They put in a blast which tore away the ground, letting the water rush out, and were drowned in the flood. The old workings had been operated through a tunnel below the shaft on the vein. Some "thought" the shaft had been 200 feet deep, some 300, some 400; the general idea was that it was 230 feet. On this latter hypothesis the men were running the upraise to miss the old workings 150 feet. It had also been figured that the old drift was 250 feet in length; in reality it was 400 feet long. The shaft was about 400 feet deep. With wrong data the two men went to their doom. Any one can, of course, be wise after the event, but if what has been editorially advocated several times in these columns had been observed these men need not have been sacrificed, viz.: An accurate map made of the underground workings of the mine and left by the outgoing management as part of the records of the mine. This is the invariable rule in many mines — to have a map of just how the work is below, up to the day of departure and filed by the outgoing management. Then as work progresses, or is resumed, there need be no guessing as to the length or location of any underground work, and the probability of such accident as the one referred to thus reduced to the minimum. The same day Frederick Duckett was killed in the Stratton's Independence mine, Victor, Colo., by falling 100 feet in a stope at the 400-foot level. The Coroner's jury found that "the timbering of the fourth level was not put in in a workmanlike manner." It is stated that the platform upon which he was standing when he fell to his death gave way under him. This, if so, carries with it its own condemnation of such carelessness in construction. The day before these three men lost their lives as narrated, Richard Tregaskis, in the Utah Copper mine, Bingham, Utah, was killed by a blast. He with his partner had drilled and loaded six holes and were trying to shoot them. Two of the fuses ignited. Tregaskis lingered in an attempt to get the other four to light, and finally giving up the effort sprang for the ladder to go up. He was 8 feet up when the two shots went off. He fell back in the winze and was dead in an hour. This appears to have been a case of familiarity with danger making an experienced miner careless. In such instances no rules or precautions are of avail. The same day Robert White at the Banner mine, Nevada county, Cal., was starting up in the skip, just off night shift, he being warned by his brother with him that his position in the skip was a dangerous one. The skip had only gone 3 feet when his head hit a timber cap, he was forced backward and crushed between the skip and shaft timbers; he was carried to his home with a broken back. The following day, in the Gladstone mine, at French Gulch, Shasta county, Cal., three men—Jno. Healey, Darby Judge and Wm. Hayes—were at work at the bottom of a double-compartment shaft, 175 feet below the main tunnel. The engineer in charge of the hoisting machinery ran the cage up into the sheaves, the cable broke and the heavy cage crashed down onto the three men in the bottom of the shaft, crushing them into an indistinguishable mass. This would appear to be a clear case of criminal carelessness on the part of the engineer.

Here are five accidents, three of which were apparently caused by individual carelessness, the first two the result of ignorance of their surroundings. More extended perusal of the local papers would doubtless disclose a larger list of fatalities.

In such cases as those cited, inquiry always arises as to the possibility of prevention of such "accidents." To any one who ever worked in a mine, it is manifest that a great portion of such grim happenings is the result of carelessness. Men become so familiar with their dangerous surroundings that they will take chances that a stranger or one knowing nothing of mine workings would shrink from. Men will work in ground that they know is treacherous; they will leap across a shaft with 1000 feet of fearful fall to smash them if they slip; they will use an iron or steel bar in tamping holes charged with powder; they will strap timbers, lagging, etc., to the outside of a skip. They will take great personal risk and do dangerous things as a matter of course and without any display or bravado, but just as a part of the day's work, partly because, as said, they become familiarized with danger, and, sometimes, because they dislike to even appear to be afraid. A large percentage of the accidents are due to neglect and improper management or lack of safety appliances, but it must be said that an equally large per cent is because of the neglect or refusal of the men themselves to use the proffered safeguards or appliances, recognizing the danger, but ignoring the likelihood of it affecting them.

The question brings up the correlative one of mine inspection in connection with proposed prevention, but occidental statistics do not seem to favor that legislative idea, for about as many casualties are reported from Western States having mine inspectors as from those not having such officials. Still as mine inspectorship is comparatively new west of the 100th meridian, it is not wholly fair to institute present comparison in that regard.

What has been said above applies solely to metal mines west of the Missouri river. That much good has resulted from official inspection of coal and other non-metallic mines is manifest. Since 1870 there have been mine inspectors and rigid rules concerning their action in anthracite coal mines in Pennsylvania, and since 1877 in bituminous coal mines in that State. For thirty years there has been State inspection of some sort in nearly every coal district east of the Mississippi river, and its good results are evident. In 1870 the coal produced in the Pennsylvania coal region, per violent death of miner therein, was 59,969 tons; in 1900 after thirty years regime of inspection it was 114,864 tons. The number of deaths there per 1000 miners in 1870 was 5.601; in 1900, 2.71. These statistics indicate a decrease of 50% in casualties—a gratifying showing—and in connection with better machinery, improved appliances and the general advance in mining methods, must justly be credited to efficient mine inspection.

The chief objection to the appointment of a mine inspector in California, for instance, is the just dread of mine owners in the possibility of being saddled with incompetent officials possessing a political pull, and with well developed sense of "touch." An appointive office is sometimes open to these objections. California and other mining States would confessedly be better any day for the creation of mine inspectors if the incumbents were thoroughly efficient, "but," say the objectors, "a man who would make a good mine inspector can earn twice as much as a mine manager or superintendent than he could be paid by the State." So that the first requisite would be to attach sufficient salary to the office to enable the commonwealth to get honesty and ability. To properly fill the office of mine inspector would demand a high degree of talent; the incumbent would have to be an unusually able man. Wherever created, the office of the mine inspector is to enforce enacted law, and reduce number of casualties. To do this he must become an educator to a large number of mine foremen; he must also be not only an instructor, but a conveyor or transmitter of information concerning improvements. He has great opportunities, to use or abuse. He sees and notes the various appliances in use at all the mines he visits and can suggest the adoption where applicable of improvements that have been used successfully in other mines. He is called any time of the day or night anywhere in his jurisdiction where accidents occur, and assumes the responsibility for the subsequent proceedings. A man that is able to do all this, to act quickly, intelligently and impartially; to hold aloof from even the suspicion of dishonesty, is worth big money as a mine manager for some large mining company where he would be spared the contumely and annoyances inseparable from such a position.

In the Pennsylvania anthracite coal regions the mine inspectors are practical men; they have had long experience in charge of mines before being appointed. They are not politicians and are not appointed to please political friends; they are commissioned by the Governor of the State on the recommendation of a board of examiners appointed by the judges of the courts having jurisdiction. The board of examination consists of two reputable mining engineers and three reputable working miners engaged in present actual work. The Governor has no choice in the selection of the mine inspectors, but must appoint the one recommended in each case. The inspectors are commissioned for five years, have reputations to maintain, and are practically certain of reappointment so long as they efficiently discharge the duties of their office.

In any discussion of mine inspectorship the difference in the personnel of the coal and the metal miner must be borne in mind. In many of the anthracite coal mines hordes of Huns and Polacks are herded, and of necessity require a censorship that would be repelled as degrading and intolerant by the western metal miner, who does all his talking and most of his thinking in United States language.

IN another column a Colorado mine manager discourses on some of the necessary qualities that go to make up a successful mine manager. At the risk of making the list too long it is here suggested that many successful mine managers have found it well to be always ready to recognize the value of a new idea, regardless of where the idea came from. Suggestions and even criticisms from subordinates in respect to details are often of sufficient value and enlarge the horizon of view. Should the tendency be to resent criticism or advice, it might be borne in mind that it were no harm to listen, and that whether the suggestion shall bear fruit would be for himself to say. Nothing that is good need ever be discarded because of its source.

CONCENTRATES.

SILVER can be electrolytically deposited on aluminum. This discovery was made at Sheffield, England.

♣♣♣♣

THERE are mines in southeastern Arizona producing bismuth and lead, the mineral being bismuthinite.

♣♣♣♣

THE American Mining Congress will meet at El Paso, Tex., November 14, and will continue in session for one week.

♣♣♣♣

THE cost of wagon transportation over good roads is usually figured at 25 cents per ton per mile, though in some instances the cost is less than this amount, and in others much more.

♣♣♣♣

ALTHOUGH mining has been vigorously carried on in California since 1848, new discoveries continue to be announced, the most recent being in Modoc county, in the extreme northeast corner of that State.

♣♣♣♣

IN determining the value of a mine it is as important to know the length of the ore shoot as to know its width and height. An ore body may have considerable width and height, but be so short as to scarcely justify a mill or other reduction works.

♣♣♣♣

IN the early days of the Stonewall Jackson mine of southern Arizona many mules were "packed" with the native silver taken from the rich veins of that mine. Native silver and nuggets of hornsilver were also found in the neighboring gulches.

♣♣♣♣

ANY person, a citizen of the United States, may locate as many mining claims on a lode or vein, that is not already appropriated, as he cares to take. The law does not prohibit the number of claims one may take or buy, and the several claims may be on one or several veins.

♣♣♣♣

THE speed with which holes may be drilled by means of a pneumatic hammer drill depends upon the kind of drill used, hardness of the rock, air pressure, and also upon the miner himself. Some men will make better headway than others when all conditions are the same.

♣♣♣♣

ZINC FUME is an extremely fine powder of metallic zinc, obtained from condensing chambers of the zinc furnaces. It is mixed with water and is used as an emulsion in precipitating gold from cyanide solutions in some mills, this method being preferred by those who use it.

♣♣♣♣

THERE is no economy in running a stamp mill so fast that the tappets strike the cams when falling. More damage is done than is gained in increased capacity. The height of drop may be decreased somewhat with the same number of drops per minute and the interference of cam and tappet thus avoided.

♣♣♣♣

WHERE the heat from exhaust steam is found insufficient to heat feed water for the boiler, steam may be admitted from the receiver of a compound-condensing engine to the water heater direct without danger. Ordinarily, however, the exhaust steam will raise the temperature sufficiently for the desired purposes.

♣♣♣♣

THE "Concentrate," page 223, in the issue of September 30, beginning "Code Civ. Proc. 1895, section 592, etc.," referred to the Code of Civil Procedure of the State of Montana. All of the States have codes of civil procedure, but in many respects these differ from one another to a greater or less extent.

♣♣♣♣

CROSSCUT TUNNELS run from the surface to intersect veins cropping a great distance away are often continued far beyond the vein without the vein itself having been noticed by the miners, owing to contraction of the vein or to some other cause. This is probably what has occurred in the San Bernardino county, Cal., instance.

♣♣♣♣

WHERE the mine is situated at the top of a vertical cliff, the ore may be safely and cheaply delivered to a mill or ore bin at the foot of the cliff by means of an aerial ropeway. Constructions of this character are not uncommon in Colorado. On the front page of this issue and on page 240 appears illustrated reference to the subject.

♣♣♣♣

A REGION wholly destitute of payable quartz mines may produce a rich placer field. In such places the gold usually occurs in small seams of ochre, clay or quartz and too far separated to make it possible to mine the mineral zone as a whole, but the erosion of such a region often results in a concentration of the gold in the gulches and depressions, forming payable diggings.

♣♣♣♣

IT is not uncommon to find hoisting plants at mines equipped with some automatic device which warns the engineer of the approach of the skip or cage to the surface. These devices are usually either bells, shaking indicators, or flashing red lights. Such arrangements are no doubt of value, but the engineer should know exactly where the skip is at any moment, and not depend upon extraordinary alarms and devices to tell him of the danger of overwinding, for the reason that placing entire dependence upon such mechanical arrangements may result in a serious accident in the event of failure of the mechanism to operate.

♣♣♣♣

THE diameter of a Pelton wheel has little bearing on the amount of power developed, as it merely determines the speed at which the wheel should run under high head. To develop 250 H. P. with a Pelton wheel, water would be required in the following quantities: Head, 300 feet, 347 miner's inches; 400-foot head, 260 miner's inches; 500-foot head, 208 miner's inches. A miner's inch is legally 1.5 cubic foot per minute.

♣♣♣♣

THE tourmaline bearing dikes of pegmatite near Mesa Grande in San Diego county, Cal., were discovered in 1896 by a field assistant of the State Mining Bureau, and attention was called to the occurrence of black, green and red tourmalines found in these dikes in the thirteenth report of the State Mineralogist of California issued in 1897. These deposits are now being worked for the pink tourmalines occurring in the granite dikes.

♣♣♣♣

AS THE ore is delivered to the mill by aerial tram, it may be that the "grease which is interfering with amalgamation" may be caused by oil dipping from the wheels supporting the buckets on the wire way. It must be this, or the oil comes from some place in the mill—dripping shafting, cams, etc. If neither of these, it may be some mineral substance in the ore that is giving trouble and not oil at all. Plumbago, arsenic, antimony, molybdenite, talc and other minerals disturb amalgamation, often seriously.

♣♣♣♣

IN the case of the claims A and B in Oregon, while claim A may lie higher than claim B, work on A if of actual value to B may be charged in part to B. A mill built on the creek to treat ore from both claims may be applied as assessment on both claims. A tunnel run on the vein on A might not be construed as work tending to develop B, while a shaft on A might be so construed. It is merely a matter of fact. The authority under which assessment work is done on one claim for the benefit of several claims of a group is the United States Revised Statutes, Sec. 2324.

♣♣♣♣

ON PAGE 169 of the issue of September 9, in the "Concentrate": "A dynamo can usually without material alteration, or without any at all, be employed as a motor. Motors were introduced for convenience and for particular purposes. A single dynamo may run any number of motors within the range of its electro-motive force": "Electro-motive force" might have read horse power. In electrical engineering 746 watts are figured as equivalent to 1 H. P. The watt is the term employed to express electrical power, and is obtained by multiplying the voltage (electro-motive force) by the amperes or current.

♣♣♣♣

IN the case of clarifying slimes referred to by the correspondent from Anaconda, Mont., the material was not acid, but consisted largely of fine silica and impalpable hematite dust. It is not essential that the slimy material be acid to make it possible to clarify it with lime. If no acid be present it is, of course, necessary to avoid excessive alkalinity. The addition of lime to material to be treated by cyanide process must be made with caution. The same methods are not always applicable nor successful. At some plants the milk of lime is employed, while at others this method is unsatisfactory. Some crush the lime with the ore in the battery, others crush it separately. At the Homestake plant in Lead, South Dakota, the lime is crushed in a mortar by a single stamp and it has been found that the size of the crushed particles is an important factor in the success of the operation.

♣♣♣♣

THE cost of pumping water per ton of ore treated for milling or other metallurgical purposes must be determined by the situation, the factors being the distance and height to which the water must be pumped, the amount required, and cost of power for pumping and of labor. Where it is possible to pump the water to a sufficient height to a tank on some elevation near the pumping station it is better to do this, allowing the water to flow by gravity to the mine, if the distance be great. This overcomes the friction head, which in long pipe lines is considerable. Generally the cost of pumping water does not exceed 50 cents per ton of ore treated, if the pumping installation is commensurate with the magnitude of metallurgical operations. It is not economy to have a plant capable of supplying a larger amount of water than the works require. It is generally better to pump less water than the maximum amount required, and to settle the tailings and pump back a part of the water from the settling dam.

♣♣♣♣

THERE are many mines where iron has been found to contain an increasingly greater amount of copper with depth up to certain limitations. Copper has appeared in many of the mines of Leadville, Colo., with depth. The depth at which this change takes place varies greatly. In some mines it is comparatively near the surface, in others the change comes several hundred feet below the surface. No arbitrary line can be drawn. In mines where no copper appears in the superficial portions of the vein or deposit, and it does begin to appear with increasing depth, the "signs" should be followed. It may be that the amount of copper present will never become an important factor in the value of the mine, but if the copper contents add any value to the mine at all it should be welcomed. The normal zone in a copper producing mine is usually found to be low grade, sometimes less than 1%, and yet this class of ore may have produced a zone of great enrichment at higher levels, while at the surface no copper is found in the ore at all.

♣♣♣♣

THE object sought in adapting briquetting to the smelting of fine ores is to obviate the loss ensuing from the escape of flue dusts, concentrates and granulated mineral fines during the smelting process, and to put the fine mineral ores, tailings, and similar fine materials into such a form as will admit of their being treated in the smelter without loss. Considerable has been expended in experiments along many lines; many smelting concerns are operating briquetting plants for the treatment of fine dusts, and materials which for many years have been running down the canyons or into the settling basins, are carried back to the smelters and, after being solidified in the form of mineral briquettes, are resmelted with profit. Through the treatment of these mineral fines and the flue dusts and slimes from the concentrators, it has been found possible to increase the smelter output 10%, old ore dumps, flue dust, etc., containing as low as 6% of mineral value being treated by the briquetting process with profit. Briquetting as applied to fine minerals eliminates other disadvantages arising from the use in the smelter of concentrates and fine ores in their natural state.

♣♣♣♣

THE chief thing to look out for in setting up a gravity battery for telephone work is to prevent any mixing of the solutions, and care and dexterity will be required. The solution of copper sulphate is a thoroughly saturated solution, and several pounds of copper sulphate crystals are placed in the jar to maintain the solution at the saturation point as long as possible. The copper solution should about half fill the jar; the weak solution of zinc sulphate is poured carefully in on top until a layer of zinc solution is obtained deep enough to cover the zinc element when it is in place. The battery must, of course, be set up in the place where it is to be used and left undisturbed as any movement of the cell would cause the solutions to mix. To replenish the copper solution the zinc solution should first be drawn off, which can be done with a battery syringe or syphon; the practice of dropping crystals of copper sulphate through the zinc solution is a bad one, as it causes a mixing of the solutions. When the solutions become mixed and the zinc becomes discolored, which will occur if the cells are moved or shaken, or if they are left long on open circuit, the solutions should be drawn off, the plates thoroughly scraped and cleaned, the zinc re-amalgamated, and the battery should be set up again with fresh solutions. Speaking generally, the gravity battery is not a good type of cell for telephone work, as it deteriorates so quickly on open circuit; its use is practically confined to situations where a continuous current is required, and for such purposes the motor generator and storage battery are better.

♣♣♣♣

IT is sometimes said that a banker to whom a customer has paid in moneys for his current account is a trustee of such moneys, but this is a mistake. The true relation between a banker and his customer is that of debtor and creditor only, with an obligation on the part of the banker to discharge the debt in a particular manner. So clearly is this the case that if, after paying money into the hands of a cashier to the credit of his account, which is not overdrawn, the customer should suddenly suspect the solvency of the bank, he cannot withdraw it except by check. In the same way, the moment a bank clerk in cashing a check has placed notes or money in the control of the person presenting the check there is actual delivery and possession, and he cannot take them back. Should a customer overdraw his account the bank is not bound to offer the sum really due him, but can rightly refuse to honor the check. When a check is indorsed the indorsee can bring an action against the drawer, just as the indorsee of a bill can sue the acceptor. A check is not an assignment of any portion of a debt due from a banker to his customer, but simply a request with which the banker has promised to comply. Should the latter fail to meet his engagement to pay, all things being in order, the customer can bring an action against him and, although no actual loss has been sustained, will be entitled to nominal damages, as the obligation of a banker to honor his customers' checks rests upon a clear and distinct promise or agreement to that effect, which arises from the course of business and the nature of the transaction. There can be an indorsement in blank or a special indorsement of a check. The post-dating of a check drawn to bearer, or order, in no wise affects its validity, and a person taking it bona fide and for value has a perfectly good title. Every banker who honestly pays a check drawn upon himself is entitled to charge the sum he so pays to the account of his customer, although the signature of the payee or indorser has been forged. A banker is bound to know the signature of his customer, and therefore, if he pays a check bearing the latter's forged signature, he cannot charge the customers' account with the sum so paid. And if the amount payable on a check has been fraudulently altered, the banker who pays it can only recover from his customer the sum for which it was originally drawn. But when there is evidence that the gross negligence of the drawer clearly afforded opportunity for the alteration of the check, the customer may have to bear the loss himself if there has been no want of care on the part of the banker in cashing the check.

Mine Manager's Requirements.

TO THE EDITOR:—Even in the present advanced stage of progress in mining, one sees many cases of extravagance in operating mines. Notwithstanding the excellent work of the periodicals devoted to the mining industry, more than one mining venture, involving perhaps the total capital of some man or company, is allowed to proceed as if it had no management whatever. Perhaps that important function is vested in the person of some influential friend or relative, who must be provided for, or some antiquated hobbyist may have here a chance to air his pet ideas, or a dreamer, whose principal feature is the profundity of his appearance, may prove the stumbling block.

The management factor is of primary importance. On it depends the mutual relations of owner and miner. The capitalist and promoter by their very nature have little in common with the man who does the work. The theorist being on his own intellectual plane appeals more directly to him, and the miner has an inherent contempt for the methods of the scientist, meeting him with the trite observation that one man can see no farther into the ground than another, or gold is where you find it, etc.

It is the province of the manager to demolish this barrier between mining brain and brawn, and not have arbitrary orders issued without an understanding of conditions and executed in a contemptuous and half-hearted manner.

There are many kinds of managers, who manage with varying degrees of success. Prominent among these are the specialists in some branch of science which may or may not pertain directly to the working of a mine. Here there is perhaps a civil engineer or a master mechanic, or perhaps one who has attained distinction in metallurgy. Sometimes a butcher or even a dry goods merchant or other tradesman will be observed among the ranks of mine superintendents. Now any of these may meet success for a brief period, but there comes a time when the strictest economy is needed and even trifling extravagance of the past will be felt.

It is here that good management becomes imperative, and where the specialist is apt to fail. Lines apart from the one with which he is thoroughly conversant will not be in condition to meet the new requirements, nor will they assume due prominence in his eyes.

One who is pre-eminently a business man will naturally see the numerous opportunities for saving in the purchase and transportation of supplies. He will not leave necessary material until the last moment and then have it hurried through at much expense, when the slower freight would have answered the purpose. Nor will he neglect to watch the market reports when buying. Thus it is with specialists in any line, while applying their efforts to their own particular branch; others equally important are overlooked.

There are numerous ways in which economy may be practiced: Buying and selling, keeping in mind not only what is needed but what may be needed, always having on hand a supply of necessary material, for in waiting and doing without and hurry-up orders much money is wasted. In transportation local conditions must be studied; roads kept in good shape for bringing in men and supplies will always pay for themselves, not only cheapening supplies, but also bringing in a class of men who are not compelled through incompetency to expose themselves to the worst conditions. For the same reasons accommodations and working conditions should be kept up to the best possible standard.

It is unnecessary to revert to possibilities in sampling, mining, milling and handling of ore, the placing or handling of machinery, simply treating of the man who must superintend these various lines of business. It has been exemplified many times that the student fresh from college and without practical training is not able to handle a problem so various and intricate. No more is the miner, who has spent a lifetime under the ground studying how to rend the rocks, capable of dealing with such abstruse problems. Yet we must admit the knowledge which the miner gains is an invaluable acquisition to the fund which the manager should possess.

There is a capacity which neither experience nor study can be said to produce entirely. It is an inherent quality which experience alone will discover; that is the power of handling men. Such a power should belong in an eminent degree to a superintendent of mines. The large amount of machinery needed to work a mine makes it incumbent on him also to understand the installation and operation of the same. Surveying, too, is an important feature in mining operations. The mine superintendent who can survey knows where he "is at," and where a map of the workings is kept at hand he can direct operations to the best advantage. A good general knowledge of various metallurgical processes also is imperative. The reasons are as obvious as that an engineer should know the location of the throttle of his engine. Yet how many "supes" are there who could not start the mill or run down an assay. As the great industry grows the importance of geology, mineralogy and kindred sciences in the practical field become more and more evident. So our manager must be versed in these lines. He must also be a bookkeeper, a draughtsman and electrician, in order that he may more thoroughly oversee the workings of those under him There are emergencies arising every day with which the guiding hand must be able to cope, or money and time are wasted in searching for a master to overcome them.

One of the most serious troubles he can have is a lack of funds for carrying out plans known to be essential. Directors are crying to cut down expenses and output is growing sensibly less as the more favorable ore bodies are becoming exhausted and there is no development of workings or plant to meet new requirements.

Here is a juncture that emphasizes the utility of figures and plans for guidance, with of course a liberal allowance for possible deviations, and margins varying with the knowledge of conditions.

With such plans it is known what will be necessary in the shape of plant, etc. There need be then no costly delays caused by some essential factor being thought of just when needed. Nor will there be the extra expense of substitution in some part of the plant which has been found inadequate for development of the mine, and the lack of harmony often seen in the various parts will be avoided. One piece of machinery will not be using power out of proportion to the amount of work to be done. Allowance can be made for growth within close limits. Second-hand machinery is not a very desirable asset.

Of course it is easy to say what the manager shall know and do. But no doubt many have found it a serious problem to secure the man who has these multifarious branches of knowledge blended in the right proportions. One sees advertised in your columns that a man of experience is wanted. What this experience has been, under what conditions or with what result, does not seem to cut much figure. Again a man finds favor who can produce an array of recommendations, no weight being given to the fact that the writer of such documents has less at stake than the reader.

On looking about one can see here a field that has not been sufficiently supplied to have brought about any considerable amount of selection. The requirements are so diverse that only recently has it been possible to encompass their acquirement in one lifetime. The occasional college man who is not afraid to labor with his hands for a time has an advantage not to be despised. No less is that of the student miner or mechanic. Though previous experience is essential, where delays and expense liable to experiment would be fatal, it is a poor criterion except in so far as conditions are similar. Of course failure is liable, but progress is based on failures.

Telluride, Colo. MINE FOREMAN.

A Homely Suggestion.

TO THE EDITOR:—In Sierra county, Cal., Canyon creek, above Devils gate, was evidently once a large lake. Into this lake flowed many small streams, from the gulches cut deeply into the sides of the surrounding high mountains. Mt. Filmore is the third highest mountain in California; its peak is over 3000 feet above Poker Flat, which is situated at the bottom of the ancient lake site, where Canyon creek now runs. High up on the sides of the mountains are many abandoned placer mines, in channels of ancient river beds, formerly profitably worked by hydraulic methods.

About 1000 feet above the bed of Canyon creek are the deep cuts made as parts of the work on a large canal, designed to bring water to the hydraulic miners from Gold lake, 20 miles distant. On all sides are the evidences of past extensive hydraulic mining done here. Over $3,000,000 in gold was taken from the mines around Poker Flat, which is but an index of what remains. As a result of the restraints on hydraulic mining, this fact is worthy of consideration, as a typical case, and the question arises, Cannot something be done to enable the miners to take out the gold that remains in these mines?

On looking over the ground with this object in view, there is presented an apparently very simple solution of the problem. The boundaries of the ancient lake site are high mountains, on all sides except the outlet, where the waters of Canyon creek pass through a narrow slit in a narrow wall of rock. This opening is over 100 feet in height, and part of it is less than 40 feet in width. Far above the gate, on the mountain side, are crags, on the up stream side; a few well placed shots would throw down enough rock to close the gate, and thus, with the necessary chinking, a debris dam could be formed that would restrain all of the objectionable material brought down from the hydraulic mines on Canyon creek and its tributaries, from Devils gate to Gibraltar, a distance of 7 miles.

Farther down the creek, other places where high rocky points, on each side, are not far apart, might be utilized in the same way. It is not necessary that, in all cases, the full height of these dams be made at once. When sufficient height to produce the desired result is reached, the mining can go on, and the dam be raised as may be required, the object being to provide a barrier against boulders and gravel, and a check pool to make slack water in which the heavier material will settle; the lighter portion that remains in suspension in the slack water will not be deposited by the running water of the lower streams. Canyon creek is a tributary of the Yuba river.

With this proposed dam at Devils gate, 1 mile down stream from Poker Flat, as a type, other hydraulic mining regions might locate similar suitable dam sites, and thus aid many abandoned mines on ancient river channels to yield abundance of gold by the cheap, simple method of hydraulic mining.

Downieville, Cal. JOSEPH VOYLE.

A Tough Experience.

TO THE EDITOR:—Frequently I read accounts of mining and milling methods that show success. Just by way of variety I send you a truthful narrative of what may be considered a failure. You said some time ago that "failures were but stepping stones to success." I believe it, and have a few good-sized boulders to start on. I represent one class of your subscribers, the class that is trying to do a little mining in a small way on a small capital, the class who get a few dollars ahead and are then willing to risk them in trying to do better for themselves and a few others, for it is not possible to work a mine to any extent without furnishing employment to others. My mine is a ledge of free milling ore 2 feet in width, carrying a good percentage of sulphurets. It had been worked in the seventies and abandoned on account of the ore being low grade, and also a rush of water, which stopped the work. Five years ago a friend of mine tried to open up the mine with a whim, and while he took out enough ore to pay him for the outlay, he could not get below the 80-foot level without putting in a steam plant, which he was unable to do, so he gave it up, leaving about 100 tons of ore on the dump that assayed $5 per ton and more. As it was a long, hard haul to the nearest mill, it would not pay for the hauling and milling.

Having known of the mine for a number of years, and having had a long experience with a "poor man's mill"—i. e., an arrastra—I tackled it, putting in a steam hoist, pump and arrastra, the latter at the mouth of the shaft, to run the whole with one boiler and engine, having everything arranged conveniently, so that one man could do all the top work.

Just as I was ready to fire up to test the machinery, after over a year's hard work, the shaft caved, coming together for over 40 feet, so I had to retimber the shaft from the top to the water, the latter making as high as twelve buckets of water to one of waste. But, as I wanted lots of water, of course, that suited me. I finally got started and everything ran smoothly. I ground out a ton of the dump every six hours, making two tons per day of twelve hours, and the way it took the "quick" was certainly encouraging. "Stocks" went out of sight, and I knew I "had it" at last.

But pride preceded my fall—the "knock" was there all right and I got it. I had a tank alongside the shaft that I pumped into from the sump. I used to fill it every night after shutting down the "mill," as it not only saved time by doing so, but it also ran down the head of steam. On the fifth night after starting to grind something went wrong with the pump. I went down the shaft in the morning and found only 6 inches of water in the sump. The water had quit in the mine. I tried to run the dump through, but I had to wait a whole week to get enough water to grind a batch of ore. The deeper I got into the ore dump the more talc and clay showed up, which took three times the amount of water the clean quartz had required. So I concluded I was surely "up against it." Now, tell me, was this a case of bad judgment, or is there such a thing as bad luck?

Piute, Cal. MINER.

Steam Shovels in the Atlin District, B. C.

One of the companies operating in the Atlin district, in British Columbia, the Northern Mines, Ltd., recently completed the installation of a steam shovel plant, for placer mining purposes, says the Canadian Mining Review. The plant includes a shovel, with a capacity of 1000 yards in ten hours; an auxiliary hoisting plant; 2000 feet of flume, and 200 feet of sluices. The shovel has been placed on a stratum of clay cement in a pit excavated for the purpose. The dirt is deposited by the shovel into skips holding 1¼ yard, which are hoisted by the auxiliary plant on a cableway conveyor some 40 feet to the dump box. At the end of the dump box there is a grizzly which cuts out all rock over 3 inches, from there the gravel travels over 60 feet of block riffles, at the end of this sluice there is another grizzly which cuts out all material over ⅜ of an inch, and the remaining gravel then passes over another 40 feet of sluice to the dump. From the height of the sluices, some 40 feet, there has been provided an ample dump, and the possibility of a block by tailings has been greatly minimized. During subsequent tests for a three-hour run some ninety-five buckets were handled and it is estimated that 800 yards per day can be handled with ease.

Transportation in Colorado.*

Written for the MINING AND SCIENTIFIC PRESS.

Transportation facilities in Colorado are being improved upon each year. It is not uncommon to see large pack trains consisting of burros or mules carrying ore from the mine or mill to the station and returning with supplies for the mine. In the San Juan country, especially, a large amount of the ore is carried in this manner, as many of the mines are inaccessible for railroads or wagons, and in some instances, where there is a fairly good road, the operators seem to think it the cheapest and most economical to pack the material in preference to hauling by wagon. At the Tomboy mine, near Telluride, they have a good wagon road to the mine and mill—about 6 miles—but most of the material is packed on mules or burros for this mine. Several of the other mines, such as the Smuggler-Union and Liberty Bell, have their mills in the valley, on the railroad, and the ore is brought from the mine to the mill by aerial tramway. The aerial tramway is undoubtedly a great benefit to this section of the State, as the mountains are extremely high and the mines are in out-of-the-way places, where it requires several miles to reach by wagon road or trail, while the tramway is built over the most precipitous moun-

Fig. 7.—Man Crossing the Chasm on Aerial Tramway.

tains and across gulches. As an illustration of tramway building, the Old Hundred mine, on Galena mountain, about 5 miles north of Silverton, in Cunningham gulch, is an example of what can be accomplished. This tramway is built in three sections. Beginning at the foot of the hill, in Cunningham gulch, the first section extends up the side of the mountain for a distance of 1800 feet, and is known as the Bleichert system. Of the three sections in the line this is the lightest grade, being only 35°. On the front page (Fig. 4) is illustrated the lower terminal of this section of the tramway and a high trestle over the road in the gulch. This trestle is used for hauling out the waste for the mill foundation, which is being erected at this point. At the foot of this trestle a high stone wall, built of solid masonry, has been erected in a V shape to protect the power house and terminal from snowslides. This wall is built in this manner so that the snowslide will be split and the force of the same stopped before any damage can be done. Snowslides must be guarded against in these high altitudes, and especially where the mountains are so steep as in the San Juan country.

In Fig. 2 is illustrated the loading terminal and trestle of the Bleichert tramway at station No. 1. Fig. 7 illustrates the jigback tramway, with a man on board, between No. 1 and No. 2 stations. This line is 760 feet long and the steepest point is about 50° angle. The second jigback, between No. 2 and No. 7, is 2200 feet in length and has an angle of 63°. To appreciate the difficulties in erecting such a line, it is necessary to take a trip over it. There are several lines in the district much higher from the ground, but none quite as steep. To one not accustomed to riding the tramway lines, it looks as if the bucket was going straight up. The sensation cannot be described. The total length of the three lines is 4750 feet, with a fall of 2200 feet.

Fig. 3 shows the boarding house and upper terminal of the upper jigback. This boarding house is built on the side of the mountain, and in order to get room enough it was necessary to blast out of the solid rock. From the porch to the bottom of the next stopping place it is several hundred feet, almost perpendicular. The material for this boarding house and terminal was packed on burros from the railroad at Howardsville, 4 miles north of Silverton and 1 mile from the lower terminal of the tramway, up Cunningham gulch, where a trail was struck and followed to the top of the mountain, making about 5 miles by trail and less than 1 mile straight up the hill, where it was lowered down in an improvised chute a distance of 500 feet. A steel range for the boarding house was also handled in this manner. This work was done in the dead of winter, and anyone familiar with the San Juan country during winter months will understand the trials and tribulations of a tramway builder at that season of the year.

The pack train in some sections is almost a necessity, as to build wagon roads would mean large amounts of money, and until the country is more thickly settled and more mines opened up the pack train must of necessity take the place of the railroad and tramway. The pack train shown herewith consists of seventeen mules carrying 3400 feet of 1⅛-inch wire cable in one piece for use on an aerial tramway.

In Leadville some of the ore is loaded from the ore bin at the mine direct to the railroad cars for shipment to the smelters, and in many instances it is hauled by four, six and eight-horse teams to the railroad.

In Gilpin county, at Central City, the majority of the mines are located on the line of the Gilpin County Tramway, which traverses the hills as far as Russell Gulch and down to Black Hawk, to the mills, where it connects with the railroad.

In Cripple Creek it is interesting to see the number of railroad tracks circling here and there around the hills to the different mines in the district, and to watch the trains as they are loading with ore for shipment to the mills and smelters. In this district, which cannot be said of any of the other districts in the State, the men are enabled to live at home and catch an electric or steam train at a certain hour in the morning or at night for their work, and which takes them within a few minutes' walk of any of the mines.

It is believed that in time a majority of the mining camps will be equally as well supplied with transportation facilities. One thing in favor of Cripple Creek, the hills are not so hard to get around as in the southern part of the State and in other localities, although the grade on some of the railroads entering the camp is very steep.

There is now considerable talk of an electric road being built to the different mines in Leadville district, which, if constructed, will be the means of handling much lower grade ore than at present.

Southern Rhodesian Gold Mining.*

Written by C. E. PARSONS.

The conditions existing to-day in southern Rhodesia are widely different to those of a few years ago, the general welfare of the community being more dependent upon the existence and prosperity of small individuals than it has been in the past. The growth of tributers and small local syndicates operating mines of their own or properties originally developed and leased to them is one of the most noticeable features.

The value of the gold for the year ending March 31st, 1905, was £1,120,528, or 31.8%. The return for June, 1905, was valued at £127,812, which constitutes a record. This amount was contributed by seventy-two producers, of which about fifty-six were individuals and local syndicates who have embarked their own capital and labor in the various enterprises.

Of the total value of gold produced for the month of June, over £38,000, or 30%, emanated from small owners. From this it will be seen what an important factor they represent. In June 774 stamps or their equivalent were operating, and at the present moment over 200 further stamps or their equivalent are under order.

A large number of properties which have not yet reached the milling stage should be producing in the near future. Of these the following may be mentioned: The El Dorado, Sabiwa, Giant, Jumbo, Battlefield, Clifton, Yankee Doodle and Etna. All these mines have considerable ore reserves. Milling has just commenced on Qaika and Beatrice mines, neither of which figures in the June output. In two other cases milling plants are being increased. Allowing for the exhaustion of several of the existing prop-

*Page's Weekly.

erties, a progressive output should be maintained.

Rhodesia has advantages over the Transvaal in that it is better timbered and watered. Against that, railway rates are high and materials in consequence more expensive. It has cost the inhabitants £9 10s to £16 a ton for goods imported by them. Railway rates, however, are shortly to be reduced about 25%. The configuration of the country in a few instances, together with water power, is in its favor. This applies principally to the Umtali district. The ore deposits do not possess the permanency and stability that obtain in the Rand conglomerate series, but compare favorably with those on most of the other gold fields scattered over the globe, both from a geological and mineralogical standpoint.

It is not too much to say that Rhodesia offers a very wide field for small mining propositions. At the same time low-grade reefs and bodies of ore exist that cannot be well handled by individuals owing to the heavy outlays demanded. Most of the gold is derived from quartz veins and reefs, but a large percentage is also extracted from diorite, schist, and a small amount from alluvial deposits.

In the Lomagundi district a deposit of auriferous conglomerate on the El Dorado mine is attracting a great deal of attention, and excellent results are being obtained. Small owners may now work to a profit under arrangement with the Chartered Co. Should they make more than £100 profit a month, a royalty of 2½% is payable on the gold won. If, therefore, profits do not reach £100, no royalty is demanded.

The auriferous area is extensive, large and small gold mines being scattered throughout the territory and exist at wide intervals apart, often many miles from a railway. Mines treating varying tonnages, from 14,000 tons to a few tons of specimen stone, or even less, are the order of the day.

Working costs are difficult to get at, conditions varying to such an extent that we find every case stands by itself. The president of the Chamber of Mines in his last annual report selects seven representative mines. Two large low-grade mines working under exceptional conditions are not included. The following are his approximate figures:

	£	s.	d.
Mining	0	10	2
Milling	0	4	10
Hauling, crushing, sorting and headgear	0	2	9
General	0	3	0
Cyaniding	0	3	2
Total	1	3	11

This does not include redemption, depreciation, etc. With these additions the amount would work out to about 30s.

Tributers working on a smaller scale, having fewer expenses and not including their own time, would probably work for from 12s to 20s per ton. This figure can only be estimated from experience. Altogether about 1200 whites and 1500 natives are employed in the mining industry.

Apart from gold, silver valued at £902 and lead at £548 were obtained in June, 1905, while deposits of copper, zinc and wolfram occur. From the Wankie collieries about 7000 tons of coal is being supplied to the railways, mines, and in other directions. Near Gwelo a water-worn deposit of diamondiferous gravel is being prospected and stones of good quality have been found.

Unlike many Australian "fields," the country under irrigation or during the wet season is capable of producing all kinds of crops, while vegetables grow well. It is an excellent stock raising country. About 1100 whites live by farming, scattered over 950 farms. These factors will assist the gold industry. The total population consists of 12,000 white people and 565,000 natives living in the country.

In most cases outcrops and the upper portions of reefs of any value have already been removed from the surface to 30 and over 100 feet by the "ancients," consequently modern mining often commences below the first level.

The general practice in Rhodesia is that adopted in other parts of the world, with modifications. The stamp battery (heavy type) finds most favor. A large number of other mills are used by themselves and as auxiliaries. One large dry crushing roller mill is treating upwards of 14,000 tons a month, and another smaller plant is being erected. Over twenty Tremain steam stamps are in operation, also ten Huntington mills. Several tube mills will shortly be at work.

Wolframite and the Prospector.

In recent years a great deal of interest has attached to the tungsten minerals, of which the most important are wolfram, hubnerite and scheelite. Wolfram is the most abundant so far as known. Considerable quantities have been mined in the southern Black Hills of South Dakota in granite dikes, and in the northern Hills in Cambrian quartzites. In Arizona and in other States it occurs in veins. The following description of wolframite, by a writer in the London Mining Journal, is of interest and value to prospectors:

Wolfram is of a black or deep brownish black color, and has a luster resembling black glass, but with a metallic or submetallic tinge. In breaking, it usually cleaves along flat, shining faces, very much like antimony, and in this respect is very different from the conchoidal fracture of broken glass. Where exposed on the surface this cleavage is not always present. On handling the mineral one is impressed with its specific gravity; it is heavier than iron, not quite so heavy as lead—about the weight of metallic copper. The following list shows the specific gravity of wolfram compared to that of other substances: Wolfram 7.8, magnetite 5, hematite 5, hornblende 3, titanic iron 5, tinstone 7, rutile and metallic iron 7, metallic copper 8, lead 11 and water (the standard).

The streak is the mark left when the mineral is scratched by a substance harder than itself, and corresponds with the powder when the mineral is finely crushed. Minerals agreeing with one another in color very rarely have the same colored streak or powder, and this fact is useful in distinguishing wolfram from those minerals which otherwise it closely resembles. Magnetite, hematite, titanic iron, manganese dioxide, tourmaline, tinstone, hornblende, zincblende, black volcanic glass, etc., are all black, or most of their varieties are, but vary considerably in the color of their streak.

The streak of magnetite, coal, manganese is black, that of tourmaline, tinstone, rutile, hornblende and volcanic glass is of various shades, but all light colored, while hematite, zincblende, chromite and titanic iron resemble that of wolfram in leaving a dark-colored streak tinged with brown or red.

The hardness of a mineral is also a very useful test. Titanic iron, chromite, wolfram, hornblende are about as hard as a common knife blade; while hematite, tourmaline, magnetite, tinstone, rutile and franklinite are all harder.

As an example of the working out of the various tests how to know wolfram, say I have a blackish mineral. Its weight at once impresses the observer. It would, therefore, not be hornblende, chromite, zincblende, tourmaline nor rutile, but might be either wolfram, magnetite, hematite, titanic iron or tinstone (specific gravity test).

A piece now very finely crushed gives a powder or streak which is neither black nor light colored. Taking those among which the mineral might be found in the previous tests, it will be seen that it cannot be tinstone (light colored) or magnetite (black), but being reddish or brownish may be wolfram, hematite or titanic iron (streak test).

If one now takes a small piece of the mineral and tests it in a blowpipe flame and the mineral fuses or melts on the edge or corners, it is therefore not hematite nor titanic iron, but probably wolfram (fusible test).

Now break from that piece a flake, and the clean, bright submetallic luster of a cleavage face is shown. The presence of the mineral is confirmed (cleavage and luster test).

I thought the above may be some guide to the wolfram prospector, but to those more advanced I append a chemical test.

CHEMICAL TEST.—As a tungstate of iron and manganese gives a gray, infusible mass on charcoal, with borax, and lead gives colorless beading in the oxidizing flame; in reducing flame gives a yellow bead while hot, which changes to yellowish brown when cold. With microscosmic salt it gives a colorless bead in the oxidizing flame, while in the reducing flame it is dirty green when hot and becomes blue on cooling; on the addition of iron it is blood red.

Wolfram when present in small quantities may be detected as follows: The sample is fused with about five times its weight of sodium carbonate, the mass extracted with water, and the tungstic acid precipitated in the form of a white powder by means of hydrochloric acid. The precipitate becomes yellow on boiling, and is insoluble in excess of the acid, but dissolves in ammonia. The solution after acidification gives a deep brown coloration with potassium ferrocyanide, and after some time a precipitate of the same color separates out. The solution, after adding the ammonia, gives a white precipitate with silver nitrate and yellow stannous chloride. On acidification with hydrochloric acid, and warming, the precipitate becomes a beautiful blue color, which is very characteristic. If wolfram is treated with strong sulphuric acid and some zinc added to the solution, the solution will have a deep blue color. Wolfram is usually associated with tinstone, and for a long time the separation of the minerals was a matter of considerable difficulty. It is now effected by roasting the crushed minerals with carbonate of soda, by which means tungstate of soda is formed and the tin ore can be separated. The tungstate of soda thus formed is used with starch for rendering light fabrics such as muslin uninflammable. It is also employed as a mordant by dyers; it is also used for hardening plaster of Paris, and it is the chief source from which tungstic acid is derived.

For the estimation of the quantity of the wolfram present, the best method is as follows: Take ten grains of the substance and boil for about an hour with twenty-five cubic centimeters of pure hydrochloric acid, then add five cubic centimeters of pure nitric acid; boil for about half an hour and then allow to stand about twelve hours. Dilute with an equal volume of water, and filter. The iron and manganese are obtained in solution, while the silica and tungstic acid compose the residue (with, perhaps, tin). Collect the undissolved residue, filter and wash with dilute hydrochlorine, dissolve in warm ammonia, filter off the undissolved residue—silica and possible tin. Dilute the solution and evaporate to dryness in a weighted porcelain dish; when dry, ignite carefully till it assumes a uniform yellow color, cool and weigh. The iron and manganese, etc., are then to be estimated.

Black Sand Investigation.

During the last session of Congress, says U. S. Geological Survey Bulletin No. 199, an appropriation was made to enable the U. S. Geological Survey to investigate the black sands of placer mines. Under the supervision of Dr. David T. Day, chief of the division of mining and mineral resources, samples of black sands have been collected from placer mines of the United States, British Columbia, Central America and Mexico, and concentration experiments have been carried on all summer at the Lewis and Clark Centennial Exposition at Portland, Or., in connection with the exhibits of mining machinery. A preliminary report on the progress of the investigation has recently been submitted by Dr. Day to the Director of the Survey.

A circular letter requesting samples of black sand was sent last March to the 8000 placer miners of the United States and 828 samples of sand have been received for investigation from all parts of the United States. Of these, 195 specimens have been assayed for their contents of gold and platinum, with the results shown in the accompanying table:

Adequate machinery and appliances have been secured and placed in the Lewis and Clark Exposition,

Portland, Or., in charge of competent metallurgists, to treat one carload in eight hours. The manner of treatment varies with the kind of sand to be treated. The sands are grouped in two classes—(1) sea sands, low-grade gravels and tailings from a number of dredgers and their middlings from placer workings, and (2) heavy tailings from concentration, containing the residue from the cleanup from placer mines, etc. The method of treatment so far developed for beach sands and tailings from placer mines has been to deliver the sand, after appropriate sampling, to the automatic feeder. It is then elevated to the roof of the building, passing over the screen, and delivered to an automatic distributor, from which it is evenly fed by a current of water through four iron pipes to the several concentrating machines. These machines separate the sands into three portions—concentrates, middlings and tailings. The entire concentrates and middlings are collected and samples of the tailings are taken out every five minutes. Samples of these concentrates, middlings and tailings are dried and then treated by the process devised by Henry E. Wood of Denver, Colo., by which the sands are first separated by the magnetic separator into six portions by five successively increasing currents, representing the chief minerals contained in the sands. These are finally separated by a hand batea. The end products thus separated and obtained are magnetite, chromite, garnet, olivine, monazite, zircon, quartz, gold and platinum. The amounts of these minerals are then weighed and the portions representing precious minerals are assayed.

The following results are stated to have been obtained by concentrating the black sand: Forty pounds of black sand received from Placer, Josephine county, Or., yielded oversize on 10-mesh screen 18 pounds 9 ounces, which yielded 13.754 grams of gold nuggets. The undersize through a 10-mesh screen, weighing 21 pounds 5 ounces, yielded 11.6 grams of nugget gold. Its total weight being 25.354 grams, the gold would be worth, if pure, $16.84, giving a value per ton of $842.

Another run of the black sands was from the residue from a cleanup of dredging operations from Rock Point, Or., weighing 468.6 pounds, containing quicksilver, amalgam and gold. The oversize through 10-mesh screen was 223½ pounds and yielded 3.992 grams of gold; the undersize was 243 pounds and gave 15.270 grams of gold, making a total yield of nugget gold of 19.262 grams. This, if pure, would be worth $12.71, or the residues were worth $54.20 per ton.

The Mercur Gold Mines of Utah.

The annual report of the Consolidated Gold Mines Co. of Utah, for the year ending June 30, 1905, is of interest to mining men of the western United States. During the fiscal year the daily average tonnage was 671 tons, the total for the year being 245,026 tons, of which about one-third was base ore. From all this ore an average of $2.97 was extracted, being 11 cents per ton more than the previous year.

The tailings values during the year showed a remarkable fluctuation in value. Concerning this the report makes the following statement:

TAILINGS.—The tailings, by months, were as follows:

July, 1904	$0 91	January, 1905	$1 18
August, 1904	86	February, 1905	1 04
September, 1904	85	March, 1905	1 02
October, 1904	94	April, 1905	92
November, 1904	96	May, 1905	95
December, 1904	1 21	June, 1905	92
Average			$0 98

On last year's report, the tailings averaged $1.03 per ton, hence we have gained 5 cents per ton on the extraction.

It will be observed that the tailings do not always remain uniformly low, the fluctuations being chiefly due to variations in the character of the ore. However, the general average shows a material improvement over the work of the two preceding years. It is true that we do not extract all the soluble gold, and it was for this reason that we undertook our disastrous experiment with the slime plant, two years ago. However, we aim to operate along the lines of greatest profit, and, while it might be possible to get a greater extraction of values by some other method, the increased saving might be more than offset by added expenses. The Mercur ore is a rather complex one, and many suprising things happen, from time to time, in the course of its treatment. I do not feel as if we had reached the best possible results, and even now we are experimenting along some new lines, in the hope of finding a cheap, practicable method of getting our tailings as low in practice as they can be got in impracticable laboratory tests.

ORE VALUES.—Adding the amount lost in the tailings to the amount extracted, we find that the average value of the ore treated during the year was $3.95 per ton. This most important item, too, shows an improvement over last year's results, the average value of the ore having increased 6 cents per ton. On such a large tonnage as we handle, an increase of a few cents per ton soon runs into money.

EXPENSES.—The mining costs for the year, including prospecting, were $370,934.56, or $1.51 per ton. The milling costs were $273,865.08, or $1.12 per ton. Accordingly, the total operating costs of the company, including all expenses, except construction items, were $644,799.64, or $2.63 per ton.

This is the lowest record for expenses that the company has ever made, the best previous report being $2.88 in 1903. It is obvious that this economy of operation was the greatest factor in bringing the company such a prosperous year as compared with the preceding twelve months.

The mining cost per ton shows an increase of eleven cents over last year's figures. This is not surprising when it is considered that the past year has been devoted largely to reopening the mine. Driving into caved stopes has been expensive, both for labor and timbers, and ore from such places naturally costs more to get out than from virgin bodies. There have also been some extraordinary expenses for repairs, that were charged to operating, mention of which is made under Mine Report.

The milling costs, on the other hand, have shown a most gratifying decrease, being forty-eight cents per ton less than last year. Economies have been effected in many departments, and especial attention has been paid to regulating the work, according to the principle of intensified production.

DIVIDENDS.—One dividend was paid by the company during the year, viz.: Dividend No. 20, June 6, 1905, 2½ cents per share, or $25,000.

The previous disbursements of the company were $1,030,000, hence the total dividends to date are $1,055,000.

Adding to the above the amounts paid by the old Mercur and De La Mar companies, prior to their consolidation, we find that the total of the dividends paid by the properties of the Consolidated Mercur Gold Mines Company is $3,235,312.97.

MANNING MILL.—Last summer, after making the necessary repairs, the Manning mill was leased on a royalty basis. The lessees operated the mill for a short time, but their results were so disappointing that they were obliged to throw up the lease, and the company received no revenue from their operations.

Upon the relinquishment of this lease, the mill was operated by the company until the end of the season. This run lasted from September 25th to December 5th, during which period 21,040 tons of old tailings were re-treated. The gross production was $13,587.90, or 64 cents per ton, and the total expenses were $11-452.43, or 54 cents per ton. Hence, the net profits on the company's operations were $2,135.47, or 10 cents per ton.

This spring the mill was again leased, and up to the close of the fiscal year the company had received royalties amounting to $4038.15, covering the months of April, May and June.

MILL REPORT.—The year ends with the mill generally in good condition, so far as machinery and general equipment are concerned. The building, however, needs painting, and some of the iron roofing will have to be renewed. These matters will be attended to before winter.

CRUSHING.—In the crushing department no material change has been made, except to regulate the operations of the machinery so as to handle the ore most economically. Some alterations have been made in the size to which the ore is crushed, as well as in the screening arrangement, with a view toward bettering the extraction. This department is giving good results, and is being cheaply operated.

ROASTING.—In the roasting department five furnaces are at present in operation, although during portions of the past year only four were running. The furnaces now handle a larger tonnage than ever before, with far lower operating expenses, and with only a fraction of the repairs of former years.

LEACHING.—The leaching department has been operating very smoothly during the past year. Particular care has been exercised in the method of charging the ore into the leaching tanks, as well as in applying the solutions. The consumption of chemicals has been comparatively low, that of cyanide being .82 pound per ton of ore.

The tailings tracks were changed, and new cars provided, to admit of the use of horses in tramming out the tailings, which are now being discharged by contract, at a considerable saving to the company over former day's pay work.

MINE REPORT.—The past year has been an interesting and important one in the mine. Broadly speaking, the work has largely consisted of reopening the older workings. Early in 1904 the property was in a precarious condition. A considerable portion of the mine was caved, and had been abandoned as worked out. This seemed surprising, in view of the fact that the various blocks of ground had never yielded anything like the quantity of ore indicated by the original development. Our more recent operations have made it clear that the caving of the various stopes was not due to exhaustion of the ore, but to faulty mining. The mining was nearly all done with stulls. This system is very good under certain conditions, but the Mercur ore bodies range from 20 to 80 feet in thickness, and to attempt to mine such an ore body by means of stulls, even though the vein be taken in slices, or "subs," is wholly impracticable, and it is not surprising that in some of our best stopes not over one-third of the ore was got out before the country caved. The mine was in the first place quite intelligently prospected and developed; but the same good judgment was not displayed in the selection of mining methods.

We have done a great deal of prospecting in virgin territory, during the past year, and have opened up much new ore; but a large share of our work has been in going back into the old stopes, driving through caved ground with tunnel sets, preparatory to mining by the caving system. To persons inexperienced in this sort of work, this often seems dangerous; but, as a matter of fact, when done by men accustomed to it, it is as safe as running untimbered tunnels in new ground. Hence, there has been no apprehension on the score of safety, the principal thing to look out for being to keep solid bottom for all drifts, and not to drive over any open caves, which might let the floor of a drift through. We have been very successful in this respect, the single exception being due to disobedience of orders on the part of contractors who were breaking ore by the car. But, of course, this sort of work takes great quantities of timbers, which run up the cost of the ore while we are blocking out. Furthermore, the drifts are not made very large, so they do not produce much tonnage as they progress. Again, while in some stopes the cave drifts are all in ore just as if it were a virgin ore body, in some other places the material contains a great deal of waste rock, the waste often exceeding the ore. The ore from such places, naturally, is pretty expensive.

Taking the foregoing points into consideration, it is not hard to understand why our mining costs increased a little during the year.

ORE RESERVES.—I wish it were possible to make a close estimate of the tonnage of ore in sight in the mines, but it must be apparent to anyone reading what I have said about the workings in caved ground that this is out of the question. The best I could hope to do would be to make a guess. I said last year that I thought the ore then developed ought to admit of profitable operation for at least two or three years, and that there was no reason to doubt that during such a period many new developments would be made. The year's results have shown that that estimate was certainly conservative. I feel just as confident to-day that we have at least twice as much ore in sight as we had a year ago.

IMPROVEMENTS AND REPAIRS.—Owing to the great difficulty we have had with hand sampling, we decided last year to build a small sampling mill at the Mercur mine. The mill went into commission in December and has been of great advantage, because instead of having to rely upon samples of a few pounds, we can now run through a ton at a time, if desired, thereby getting much more reliable results. In building the plant, we used a good deal of material and machinery we already had on hand. The financial statement shows the cost of the plant to be $1514.76. As a matter of fact, it cost about $500 more than this amount, but the difference was charged to operating expenses.

Our large electric hoist got into bad condition during the year, owing to the wear and tear of seven years' operations. We are obliged to provide an entire new main driving gear, which costs about $2000, all of which was charged to operating expenses.

The timbering in the Tramway tunnel at the Mercur pockets, under the tailings dump, got into such wretched condition that it became necessary to give the place a general overhauling. Since the condition of the mine had so greatly improved as to justify the expenditure, we retimbered the entire wide part of the tunnel with 12x12 inch Oregon fir timbers, the sets being 8 feet high in the clear. This makes a commodious, safe and convenient tunnel, that will last for years. The cost of the work was several thousand dollars, and was included in the operating expenses.

These extraordinary expenditures run up the cost of mining. Unfortunately, they are not all over yet. Among the prospective jobs for the ensuing year is retimbering the main shaft, which is in bad condition, and which is a constant source of expense for repairs.

A RECENT Reuter dispatch from Madagascar contains the following: "The draft of the decree for the regulation of mining in Madagascar is still at the Ministry of Finance, where it is being examined by the Minister of Justice. As soon as the document is returned to the Ministry of the Colonies, M. Clementel will submit it to the Council of Ministers, and will publish it as soon as possible in the Gazette. The decree divides the mines of Madagascar into two categories, alluvial mines and reef mines. In the case of alluvial mines a tax of 5% ad valorem on the gross output and an annual tax of 2 francs per hectare of land will be imposed. As regards reef mines, the system to be adopted will be similar to that in force in the Transvaal. There will be a tax of 200 francs per hectare and an ad valorem tax of 10% or 15%. The amount of the ad valorem charge has not yet been finally determined, but it is very probable that it will be fixed at 10%."

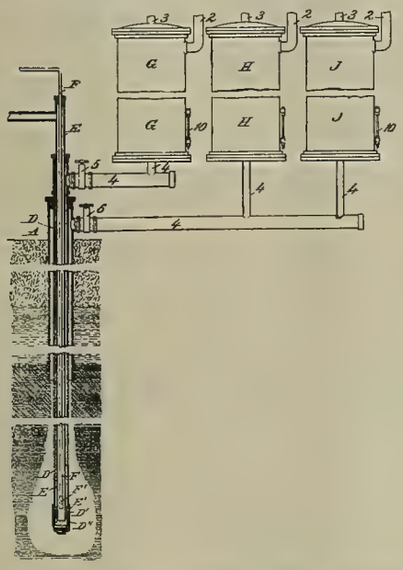
THE Council of the American Institute of Mining Engineers has accepted the invitation from the Council of the Iron & Steel Institute of England to hold a joint meeting in London in August or September, 1906, the exact date to be subsequently decided. The ninetieth meeting of the Institute, for the reading and discussion of papers, will be held at Lehigh University, South Bethlehem, Pa., beginning Feb. 21, 1906.

Mining and Metallurgical Patents.

PATENTS ISSUED SEPTEMBER 19, 1905.

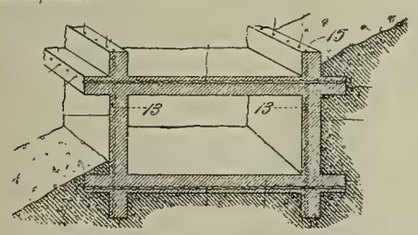
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

PROCESS OF MINING SULPHUR. — No. 799,642; H. Frasch, Cleveland, Ohio.



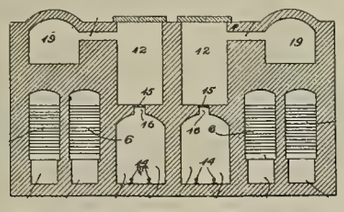
In sulphur mining in porous rock, improvement consisting in forcing hot water into underground deposit and out through walls of mine cavity, so that it flows away through surrounding rock, allowing melted sulphur which separates itself by gravity from water in mine to collect until it seals end of sulphur pipe, and introducing air or other aeriform fluid into column of melted sulphur so as to reduce its density and allow it to be raised by pressure in mine cavity.

CONCRETE FLUME.—No. 799,827; W. L. Church, Boston, Mass.



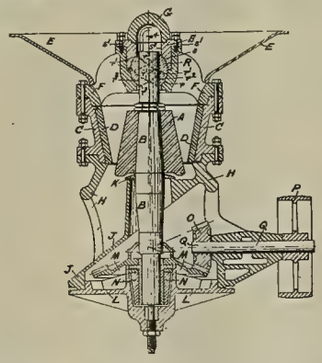
Flume comprising opposite walls having outwardly projecting flanges, and connecting wall, all of concrete and integral with each other, and series of independent transverse tie rods connecting side walls, tie rods formed with means interlocking with concrete and having ends embedded in flanges.

METALLURGICAL FURNACE.—No. 799,745; P. A. Mackay, Newcastle, New South Wales, Australia.



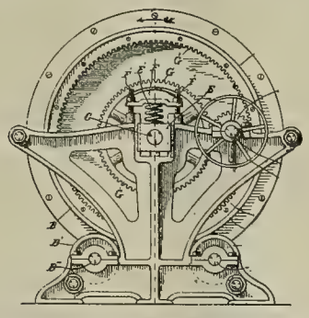
In metallurgical furnace comprised in unitary structure, combination with parallel passages or chambers extending longitudinally along center of furnace, regenerative furnaces extending longitudinally along sides of furnace, passage ways connecting regenerative furnaces with parallel chambers, partitions between chambers, each partition being hollow to form left and right reduction chamber having thin walls, oxidizing chambers extending longitudinally over regenerative furnaces, one at each side of structure, passage ways connecting left reduction chambers with left oxidizing chamber, passage ways connecting right reduction chamber with right oxidizing chamber, opening in top of each reduction chamber for receiving products to be treated, passage way below each row of reduction chambers, and trap door 15, at bottom of each reduction chamber by means of which products of each of reduction chambers may be conveyed to each of passage ways below reduction chambers.

ORE CRUSHER.—No. 799,647; P. Hart, Johannesburg, Transvaal.



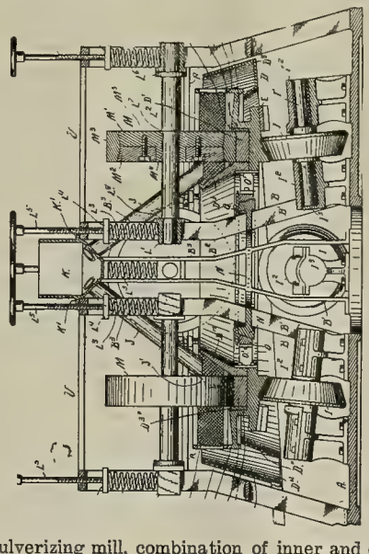
In crusher of nature indicated in combination, cone spindle and crushing cone secured thereon, means for imparting gyratory and eccentric motion to spindle, ball slidably fitted on upper extremity of cone-spindle above cone, spider forming bearing for upper end of cone spindle, spider having semispherical internal recess which is adapted to receive portion of ball and adjustable gland fitted in top of spider and having internal semispherical recess to fit upper portion of ball, gland being fitted to spider in such manner that spherical socket is formed for ball in which ball is confined vertically and permits it to rotate, gland also having hole above top of cone spindle, and a cap which serves for closing hole in gland, cap having internal recess forming with hole in gland, grease or lubricant holding box communicating with spherical socket and from which grease or lubricant can pass between sphere and socket and ball and spindle.

PULVERIZER. — No. 799,990; G. S. Knapp, Grand Rapids, Mich.



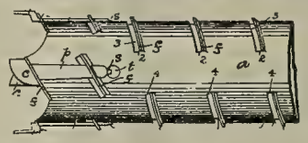
Combination of rotative case, means for passing material longitudinally through case, large roll near axis of case and movable vertically, and series of smaller rolls surrounding large roll and radially movable relative thereto, all of rolls being supported by lower side of case.

PULVERIZING MILL —No. 800,089; J. H. Elspass, Denver, Colo.



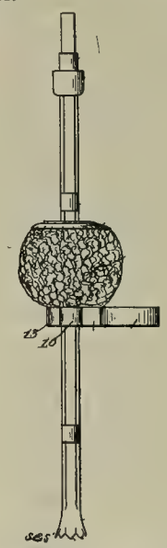
In pulverizing mill, combination of inner and outer series of posts, each series of posts having inclined lower parts whose lower extremities are outermost, upper portions of both series of posts being vertical and bifurcated, annular rotary mortar located between two series of posts, rollers supporting mortar from below, pulverizing rolls provided with axles journaled in boxes mounted in bifurcated vertical portions of inner and outer posts, tension springs also located in bifurcated portions of posts and engaging springs from above, pulverizing rolls co-operating with mortar to perform pulverizing function.

DRILL FOR MINING PURPOSES. — No. 799,880; J. Tonge, Jr., Westhoughton, near Bolton, England.



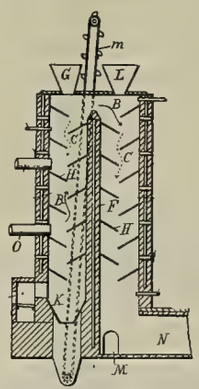
Drill comprising tubular body provided with volute flanges, plurality of flanges being slotted, and cutters provided with stems adapted to project through slotted flanges, tubular body being provided with holes or openings into which ends of stems are bent.

HOLLOW PERCUSSION DRILL.—No. 800,004; J. Murphy, Leadville, Colo.



Percussion drill having mounted thereon adjustable dust catcher consisting of body of water-absorbing material having portion thereof surrounding and engaging drill, sleeve mounted upon drill, extending partly through body and provided with integral flange abutting against one end of body, and attaching means secured to flange to which body is secured for connecting latter to sleeve.

TREATMENT OF SULPHIDE AND COMPLEX ORES.—No. 799,696; C. H. Ward, Sydney, New South Wales, Australia.



Process of treating ores containing sulphur, which consists of following steps: First, in raising temperature of crushed ore to degree sufficient to cause decomposition of sulphides by means of current of hot gases moving in direction opposite to movement of ore; secondly, adding sodium chloride to ore so treated; thirdly, subjecting mixture of ore and sodium chloride to hot gases produced during first step of process and causing such gases and ore to move together in same direction; and, fourthly, reducing temperature of commingled ore and gases while they are moving together by introduction of cooling medium.

PROCESS OF TREATING ZINC ORES. — No. 799,743; P. A. Mackay, Wenona, Ill.

Process of treating zinc ores containing cadmium sulphide and zinc sulphide, which consists in subjecting ore to dead roast, whereby zinc sulphide is oxidized and cadmium sulphide converted into cadmium sulphate, thereafter dissolving out deleterious sulphate and grinding and distilling remaining zinc oxide to obtain therefrom pure refined zinc.

Structure and Genesis of the Comstock Lode.*

The formation of the Virginia City bonanzas is peculiar, and has never yet been concisely presented. The present developments in mining work have thrown much light upon this question of genesis. In the Virginia City portion of the lode the ore occurs not in the main fissure, but in openings or veins in the hanging wall, which occupy nearly vertical positions. These veins are more nearly allied to gash veins than to what are usually called fissure veins. The secondary vein, now so productive in the Ophir ground, has brought to light some valuable and interesting facts: (1) It has been found only in the lower mine levels, either as a mere fault zone or a productive deposit. (2) From the lines of motion preserved finely in the clay gouge, the relative movement of the walls is seen to have been nearly horizontal, whether north or south the writer is not able to state definitely. From the parts of the vein observed, however, chiefly on the 2050 level, it seemed probable that the motion was to the south for the east wall, dipping downward about 4° in the same direction This corresponds to the view that the vein itself is due to a pulling apart of the rock mass, causing the greatest openings to the north, in the concavity caused by the bending of the vein to the east at the north end.

* * * * * * * *

The ores are doubly interesting from the fact that their deposition still continues, due to faulting opening up new fissures and fractures, and from the fact that the mine waters are, for such waters, rich solutions yielding very positive results to fire assay methods. The ores are moving in two ways—upward and downward.

That the ores have moved upward at more than one time has been noted best by Becker. He writes: "In the great California & Virginia bonanza several streaks or veins of very rich black silver ores, said to be largely stephanite, occurred These were separated from the surrounding quartz very sharply, as if of later origin." Again he writes: "What I have seen * * * leads to the belief that these rich concentrations were of later origin than the rest of the ore. The quartz in the C. & C. was almost everywhere a crushed powdery mass, while the thin and persistent veins of black ore running through it were very solid. A somewhat similar relation seems to have existed near the croppings, and it is not impossible that these ores were formed at the expense of others of the more usual kind at a later date, and that they occupy spaces opened in the ore masses by a faulting action."

The writer had hoped to present even more conclusive evidence of successive deposition and its recency, but owing to the fact that the lowest mine workings are not open to outsiders, this became impossible. However, such evidence as already possessed is as follows:

In the ore bodies opened within the last year on the secondary vein now worked, some pertinent facts presented themselves. The finest specimens of ore show often very perfect crystals of stephanite and argentite coating, or wedged between, quartz crystals. Coating one side, the downward side, of all the minerals, is a thin layer of calcareo-siliceous material. Below the surface crystals of ore and quartz is a layer of quartz, resting in turn upon a second layer of calcareo-siliceous matter. This shows below it a second layer of ore, resting upon quartz crystals, and so on, the series often repeating itself several times more or less perfectly. In that portion of the ore occurring in the lower depths, from which the water has been drained but a short time, the surface layers of ore, quartz and calcareo-siliceous matter showed clear and fresh, while, on standing in the open or in the higher portions of the vein, the same minerals appeared dusty and old. In some of the vugs in the lower portion of the ore body, quite a number of small but perfect rhombohedra of calcite were found; also, as noted by Becker, old fractures in the ore, caused by faulting movements, are cemented with quartz and ore. In the ores now worked, however, the motion appears to have been a pulling apart, for brecciation, though present, is rare, and the two sides of a cemented break are usually fully complementary. This process of successive deposition is not limited to the Virginia City portion of the lode, but is found quite well developed in the Gold Hill mines, and in the calcite gangue of the Justice ore body.

Further uncemented fractures present themselves as indicators of motion up to the present time, since the withdrawal of the waters by the mine pumps. The great volume of water still entering the lower workings also contributes abundant proof of fissures kept open by late motion, for the lode proper, where cut by the shaft, is reported to have been completely filled with quartz.

* * * * * * * *

The ores are moving downward by the leaching action of the acid surface waters. In this way they are extracted from their containing rocks and redeposited below. This process in the past has produced the striking nodular ores of the Andes mine, noted by King as occurring just below the level of ground water. These ores are now in their turn being attacked and again being carried below. A striking example of the ore deposited by the vadose waters was exposed on one of the levels of the Andes mine. The presence of east-west slips has already been noted as occurring here, and one of these, dipping south 60°, had opened sufficiently to allow the free circulation of water. The slip had cut across all other rocks, vein and country, and was filled with about 2 inches of solid coarse black sulphides of lead and silver. This small sheet of ore pinched out toward the bottom of the drift, and broadened above. The grain of the ore, and general characteristics of ratio of lead to silver, etc., were all different from the ore which occurs below, deposited from the deep circulation. The nodular ores consist typically of nodules ranging in size from that of a pea up to a foot in diameter, and composed of rich black sulphide ore in a matrix of fine crystals of quartz. Each nodule is completely surrounded by barren quartz, which at times may penetrate the nodule along later cracks. These quartz crystals are built upon the nodules as centers, giving them a radial arrangement.

All the facts relating to these peculiar ores tend to confirm the view of their deposition resulting from the intermingling of oxidized surface waters with deep alkaline unoxidized solutions. They are known to occur nowhere else on the lode in any mine workings, although the exploration within the croppings is very little in amount.

The acid surface waters which are now doing so much work have covered the walls and crosscuts of the Andes mine with 6 inches to 1 foot of sulphates, containing traces of gold and silver. The chief salt is the magnesian aluminum sulphate, with also large admixtures of iron and copper, which results in a remarkable variety of colors. The workings of the Central tunnel likewise show these sulphates, but in general the circulation of air is too rapid to allow of their great formation except in some favorable localities. The composition of these salts is shown as an average in the water analysis following. In the Central tunnel in one particular spot, where the surface waters are not fully oxidized, ferrous sulphate and pyrite are being deposited at the present time. Some sulphates are being formed here in delicate needle-like crystals containing a large amount of the ferrous salt. Bright, well-formed cubes of pyrite and some few dark sulphides, too small in amount to admit of testing, occur below and within the sulphates. Not infrequently a little crystal of pyrite tips a needle of sulphate where the solution is plentiful. Also, almost solid masses of the sulphide are found within the wall in the partly decomposed country rock. The water is descending along an east-west slip which dips to the south. The clay, or clayey rock, upward along this slip is full of pyrite, but this mineral is heaviest near the wall of the drift where the solution is able to cover more ground. The clays of the upper portion of the lode are all found to contain well formed but small crystals of pyrite containing some value. There is probably but one process responsible for all this, and a possible reaction of the surface waters to produce such a result may be expressed as follows:

$$FeSO_4 + 2H_2SO_4 + 7H_2SO_3 = FeS_2 + 8H_2SO_4 + H_2O.$$

This reaction is, of course, possible only when there is an insufficient supply of oxygen, as occurs locally in this part of the Central tunnel.

The water surrounding the sulphates and pyrites being deposited is strongly acid, the most so where the pyrite is heaviest. As the wall is worked into the acidity becomes perceptibly less. The ferrous sulphate appears to exercise the necessary protecting influence over the pyrite to save it from attack by the free acid or further attack by the small amount of free oxygen present.

* * * * * * *

The Comstock lode is divisible on structural grounds into two main portions: (1) The Virginia City portion and (2) the Gold Hill portion. The Silver City fault or lode (or branch, as now called) is a distinct unit, probably of a later age. The grounds for this belief are, as seen, the facts of it being a distinct fault and that the vein filling is different from that of the Comstock lode proper. The only grounds for a belief in a later age are those of structure; it is well shown that much faulting took place after the first formation of the main lode, and to combine all the facts presented it is necessary to assume a period of faulting not coincident with that which formed the bonanza gashes, but later than the first faulting. In this country of great and long-continued faulting such an assumption is not without a good basis.

The Virginia City portion of the lode is bounded on both north and south by a series of east-west faults. Also, to the north, some forking of the lode occurs, with one strong branch bending to the east in the Sierra Nevada ground. The faults or slips to the south are those approximately in and east of Bullion ravine. But few of these east-west fractures contain much secondary mineral. The few which do become veins are largely calcite bearing, and probably of different age from the others. Between these two lines of east-west motion is located the Virginia City portion, differing from the other part in having a greater relative movement of the foot and hanging walls. This motion has been so great that an unequal movement of the hanging wall block was produced, the bottom moving farther than the top, with consequent rupture. These ruptures produced the secondary vertical gashes, or veins of rifting. This motion causing rupture, however, was distinctly later in age than the first vein forming movements. Hence, when the secondary openings were formed they were filled with concentrations from the previous deposits as well as with original supplies from great depths. And there is no good reason for assuming that either the movements or the ore deposition have ceased, but rather all facts tend to confirm the idea that ore is yet being moved from place to place in the greater depths, as well as fresh supplies from below being brought up by the hot waters.

In the Gold Hill portion the relative movement of the walls of the lode has been less; there have been no rift veins formed, and the ore bodies are within the lode walls, near the hanging. The same two periods of deposition of vein filling were present here, the bonanzas occupying later fissures near the hanging wall of the earlier vein. No doubt deposition is still progressing in depth here, though not enough mining work has been done to allow a definite statement in this regard. The one exception to form in this portion of the lode, in the Yellow Jacket mine, was due to the fact that the vein, in its proper plane, did not reach the surface, so that the relative movement of the hanging wall block downward was taken up near the surface by a gash or rift.

On account of the importance of the subject, a reiterated statement is not out of place regarding the two periods of ore deposition. Had the second of these periods not existed, there would be practically no ore on the Comstock, hence the relations of these two must be of vital concern. The first period of vein filling was due to the primary faulting, and low-grade materials were placed in the open fissure. The second and later period opened new fissures, rift veins in Virginia City, and openings within the vein in Gold Hill, in which the rich concentrated ores of the bonanzas were deposited. This second period probably continues in the depths, as it would surely do above were the lode still intact from man's hand. The details of this ore deposition have not yet been thoroughly studied out, nor can they be until our knowledge of the physical chemistry of the subject is more complete.

The deep ore bodies of Virginia City have been, and will be, found within the hanging wall, in more or less vertical fissures, of which the surface east vein, the Great Bonanza and the vein now being worked are examples. More such bodies should be found by properly driven crosscuts and drifts lower down and to the eastward. There is also a large stretch of the lode above the 2150-foot level which has not been thoroughly explored. The probable reason for the peculiar rifting of the hanging wall block is that the cementing of the first fracture by quartz, and the concomitant weakening of the hanging wall by the leaching action of the ground waters, enabled the later stresses to fracture the hanging wall block as it is found. The reason for believing in the existence of still deeper similar rifts filled with ore is that the surface for 2 miles eastward from the lode shows the hanging wall block to be greatly altered by the action of hot waters, and therefore weakened. The Sutro tunnel section corroborates this, and the mine workings also show the rocks east of the lode not to be solid nor unaltered.

Also, there is considerable concentration of ore taking place from above from the surface, or vadose, waters. These ores will occur on or near the foot walls of the numerous branches of the lode which outcrop on the surface, within a few hundred feet of the outcrops. Such material is low grade, however, and, in the main, not yet available because of the high cost of mining and milling. A body of future reserves is thus assured. The low grade of these ores has been proved by numerous assays. Further, the west wall of the lode has never been thoroughly investigated, and such work might prove very profitable.

*John A. Reid, University of California, an abstract.

Automatic Plumb Bob.

J. S. J. Lallie of Denver, Colo, inventor of instruments and attachments for use of civil, hydraulic and mining engineers, has recently invented an automatic plumb bob, designed to furnish instantaneous action in elevating or depressing the bob to any desired position, without the use of screws or other devices. With it, it is stated the engineer can make the adjustment of the bob as readily while wearing gloves as without them and, when the survey is complete, the cord may be instantly coiled within the bob. The matter of proportion has been taken into consideration in shaping this new plumb bob, and it is provided with a case-hardened steel point, steel bushing in the head, rounded to preserve the cord.

Application of Electric Power to Gold Dredging.*

As the modern gold dredger is primarily a western institution, it might possibly be well to briefly describe the object of it and the method of operating it before taking up the subject of power.

The object of the gold dredger is to collect the gold from the deposits of sand and gravel which have been deposited there by the action of some river or glacier which, in its course, has broken up and carried along the rock that originally formed the boundary of its channel. When gold bearing veins exist in the rock, the gold in the course of time becomes freed from its surrounding ore and is together with the gravel deposited at some point, where the velocity of the stream ceases to be high enough to keep the gravel in motion.

Many schemes have been devised to regain the gold from these deposits, the simplest being to feed the gravel into an inclined sluice box through which a stream of water flows. The gold, owing to its greater specific gravity, is deposited in the riffles in the bottom and the gravel is carried through. To use this process on a large scale, there must be a sufficient grade to the deposit of gravel and underlying bedrock to prevent the tailings from interfering with the excavating operations which feed the gravel into the sluice. Ordinarily, a pit was sunk to bedrock and the gravel elevated by means of a conveyor to the sluice above at a height sufficient to carry the tailings away from the workings.

In many localities the prohibitive cost of water has made it impossible to work these deposits by this means. The perfection of the gold dredger within the past ten years has made it possible to work many of these low-grade deposits and many properties that have heretofore been considered worthless are now paying good interest on the investments.

The dredger, in brief, consists of a floating platform provided with an endless chain of buckets working on a ladder; one end of this ladder is fixed and the other can be raised or lowered, thus regulating the depth of the cut. The gravel, sand and boulders are scooped up by the buckets elevated and dumped into a revolving screen. Jets of water play on the gravel and thoroughly wash it. The gold, gravel and smaller stones fall through the openings in the revolving screen to a shaking table, while the larger boulders that might damage the tables and riffles pass through the end of the revolving screen and are carried through chutes to the side of the dredger and deposited. The coarser gravel is separated from the finer on the shaking table and falls on a belt conveyor which carries it to a considerable distance in the rear and deposits it, thus filling up the cut. The finer gravel containing the gold passes over a system of riffles containing mercury, where the gold is collected; the gravel and sand are washed over the riffles and fall overboard in the rear. The dredger is held in position by an anchor in the rear, and side lines from the bow permit the buckets to be fed across the face of the cut.

The first dredger that was a commercial success as a placer mining machine in the United States was installed at Bannock, Mont., in 1895. The first season it was operated by steam power, but the high price of fuel (wood was $4.50 per cord and coal $12 a ton) made the operating expenses extremely heavy and the steam equipment was replaced by a direct current electric system, a hydraulic generating plant furnishing the power.

From its nature, the dredger is not adapted to the receiving or carrying of fuel, often being operated at points very difficult of access, and by its great flexibility, electric power is the ideal motive power for this class of service and has become universally used, making it possible to reduce the working force one-half.

There are at present two of these dredgers being operated near Golden, Colo., power being furnished from Denver, one owned by the Clear Creek Dredging Co., about 12 miles from Denver, and the other by the National Gold Dredging Co., about 11 miles. It is reported that two more will be installed within the next year, but this cannot at present be verified.

The electrical equipment of one of these dredgers is as follows: One 20 H. P. three-phase induction motor for operating the revolving screen; one 20 H. P. induction motor for operating the shaking screen; one 20 H. P. induction motor for operating the stacker or conveyor that deposits the gravel in the rear; one 30 H. P. induction motor for operating the sand pump; one 50 H. P. induction motor direct connected to a 10-inch and 6-inch centrifugal pump for furnishing water to the revolving and shaking screen; two 45 H. P. direct-current motors with series-parallel-reverse control for operating the buckets; one 20 H. P. direct-current motor used to operate winches and in moving the boat and raising and lowering the anchor; one 10 H. P. induction motor for driving a centrifugal pump in the hold used in priming the other pumps and for clearing the hold of leakage water.

The direct current motors are supplied by a 100 K.W. rotary converter and a 5 K.W. transformer of 370 to 110 volts supplies current for the lights when operating at night.

The entire electrical equipment was supplied by the General Electric Co. The induction motors are of the Type "K," starting with a separate compensator and all operating at 370 volts, e phase. The direct current motors operate at 600 volts.

As to the nature of the loads on the various motors, that on the motors that drive the buckets is a peculiar one; it may be described as a combination of an elevator and a street car load with not quite as many stops and no particular need for very rapid acceleration. When beginning a cut at the surface, the incline up which the buckets travel may be only 20° from the horizontal; the soil is, as a rule, very loose and the starting torque is, comparatively speaking, nominal. The motor has only to overcome the inertia due to the mass and weight of the buckets—that is, from 400 to 600 pounds per foot of length. As the buckets become loaded with gravel the load increases. The speed of the buckets at the top of the cut may be as high as 50 feet per minute. This load is similar to an elevator load and is steady, the only fluctuations being caused by a bucket as it revolves around the lower tumbler, taking an extra large bite out of the gravel or else missing the gravel entirely. As the depth of the cut increases the load becomes heavier, because of the greater angle up which the buckets travel, the gravel being packed harder and the occurrence of large boulders.

Most of the gold is found in the gravel immediately over bedrock, and it is desirable to get all of this gravel possible. The most severe condition on the motors occurs when they are stalled, caused by the buckets striking an extra large boulder, a stump, or by the bank caving and completely burying the buckets. In such a case the motors are reversed till a little slack is gotten into the chain; the motors are again started and this reversing continued till the buckets are worked loose; whatever the nature of the obstruction is it must be overcome, because the boulders, if not dug out, will form an effective barrier between the buckets and bedrock, and upon bedrock lies the bigger per cent of the gold. On some of the newer dredgers variable speed induction motors are used for the buckets and winch drive, thus dispensing with the rotary converter.

Rotary converters, especially when operated on 60 cycles, are not entirely satisfactory, and more or less trouble is encountered in their operation when handled by inexperienced men, and the experience of dredging engineers is that the reliability of the induction motor drive more than offsets the higher efficiency of the series parallel control of the direct-current set. Actual tests on the bucket motors show them to operate at from 1.4% to 25% overload.

The induction motors driving the centrifugal pumps, shaking screen, revolving screen and conveyor are, after once started, subject to constant load, or very nearly so. Actual tests show them to be loaded as follows:

50 H. P. for centrifugal pumps	60% full load
20 H. P. on conveyor	35% " "
20 H. P. revolving screen	29% " "
20 H. P. shaking screen	34% " "
10 H. P. for hold pump	30% overload

The motor that drives the winches is not subject to any unusual load. The power required to move the boat is not great and the winches are fitted with two speed gearing and friction clutches. A good part of the time this motor is running light. Test shows this motor to operate at from ½% to 50% overload.

While the total connected load is about 200 K.W. for each dredger, the power required varies from 75 K.W. to 150 K.W., the average being about 100 K.W. Most of the induction motors are much larger than really needed, and, since they are very light loaded, the power factor is bad.

Had the power company been consulted in the selection of these motors, smaller motors would have been chosen, which would have resulted in a smaller motor investment and a better power factor on the system.

The load, from the central station standpoint, is a very desirable one. They operate the entire twenty-four hours for nine months of the year in this climate, and for the remaining three winter months it is a day load—just exactly the load the central station is looking for to improve its load factor.

As a matter of fact, the machinery is so heavy and the service so severe that they are shut down possibly 20% of the time for repairs. As a matter of general interest, I may say that the bucket train consists of forty buckets of 5½ cubic feet capacity, weighing 1500 pounds each, and capable of handling about 3000 cubic yards of gravel per twenty-four hours.

The consumption for a dredger of this size is very nearly 1 K.W. H. per cubic yard of gravel handled. Current is delivered on the grounds of the dredging company at approximately 11,000 volts, three phase and 60 cycles; it is stepped down to 370 volts and delivered on board at this pressure.

The step-down transformer station is quite unique, inasmuch as it is portable in form. The transformer house, containing three 50 K.W. oil-cooled transformer choke coils, lightning arresters and switches, is built as compact as possible and mounted on skids, so that it may be moved from place to place as the operation of the dredger progresses. The dredger is connected to the transformer house by 600 feet of 3/0 three-conductor cable. This allows the dredger to operate over quite a large area and necessitates the moving of the transformer house only once in every four months.

Since the direct-current motors can not be operated at potentials greater than 600 volts, this requires that the alternating current shall not be at a greater pressure than 370 volts, and, as the induction motors must be built for this voltage, they must all be special machines. This departing from the line of standard operation necessitates the motors all being special makes and the installation more expensive and difficult to replace in case of accident. This is a strong point in favor of the induction motor drive on the buckets.

In conclusion, I will say that the rate to be charged for this class of service can only be determined by the costs of generation and the costs of construction, each case requiring a separate analysis, the construction costs in most cases being so large that the business might be found unprofitable on a straight meter rate, unless it contained a heavy minimum to assure the central station of continuity of operation, and I would advise the use of a rate similar to the Doherty, or else a sliding scale.

*A paper presented to the 1905 meeting of the Colorado Electric Light, Power & Railway Association by J. F. DOSTAL.

The Ventilation of Mines.

NUMBER VII.

GASES DUE TO EXPLOSIVES.—Mr. Mann's special report deals very fully with the nature of the gases produced by firing of explosives, and the accidents recorded show that the vitiation of the mine air from this source is liable to be very serious, and that there have been more than a few deplorable fatalities from it, though the total number is, after all, surprisingly small when compared with the immense amount of explosives used, as pointed out by Mr. Mann. The most distressing cases are those in which the oxides of nitrogen appear to be the active agent, the sufferers experiencing little inconvenience at the time except a good deal of coughing, and having no warning at all from the way the candles burn that the air is bad. The circumstances under which part of the explosives burns instead of exploding are not completely determined and are not easy to find out. Out of the hundreds of charges fired daily, it is only very rarely that one burns, probably many thousand plugs exploding completely for one that takes fire. When the percentage is so small as this, it is clearly very difficult to determine what are the causes of failure to explode. The experiments carried out by Mr. Mann showed that complete explosion could be obtained over and over again with overloaded holes and weak detonators, so that neither overcharging nor undercapping can be relied on to produce incomplete explosions, as has been commonly held. Nevertheless, it has been shown that there are often causes at work which would tend to reduce the strength of detonators, as, for example, leaving them exposed in moist workings; and we would therefore recommend that all detonators should have the full strength prescribed for their particular number, as laid down in Mr. Mann's report. It seems possible that in a very minute percentage of cases the explosives may be bad, but these are so rare that the chances are enormously against the bad plugs being pitched upon for testing. In continuous work, however, every one of them must be used some time. The same may be said of detonators and fuse; one bad cap or piece in 10,000 would almost certainly escape testing, but would be found sooner or later in working through the stock. One such bad piece may cause an accident, while other plugs from the same package, or caps from the same box, or pieces of fuse from the same coil, may be tested time after time and proved to be perfect. Absolute uniformity of manufacture cannot be guaranteed, and it seems just as likely that inexplicable explosions and burning of charges may be due to the very rare occurrence of bad materials, as that it is brought about by any of the causes popularly assigned to it. Nevertheless, our inquiries have led us to the conclusion that the general quality of the explosives used in this State is good; and it does not seem possible in practice to greatly improve on the methods of testing now employed. Age of the explosive and the manner in which it has been stored, may have a good deal to do with deterioration of quality. It has been pointed out in Mr. Mann's report that the merchants' magazines are frequently inspected; but it appears essential, also, that stocks should not be kept in the mine magazines for too long a time without similar supervision. Several witnesses, who were practical miners, told us of their having met with instances of charges burning instead of exploding—some having actually seen the bright glare of the burning stuff, others judging by the characteristic smell and by the state of the holes afterwards. It seems possible that the cause of this burning may be that an earlier shot has blown off the top of the charge and the detonator with it, and ignited the remainder without exploding it, as it is well known that such "cut-outs" occur not infre-

quently; and it seems also possible that a cut-out charge might be ignited by sparks from showers of stones thrown out by the other shots. Another cause is probably the practice followed by some miners of burying the detonator deeply in the charge; for if the fuse "spits," as it is liable to do occasionally, it might ignite the explosive before the detonator is reached. The rate of burning of the explosive is extremely rapid, and a considerable amount may therefore be burned before the fuse ignites the buried detonator, and thereby explodes the remainder of the charge. In Mr. Mann's tests it was only when the detonator was buried that a strong reaction was obtained for nitrous fumes in the gases resulting from the explosion. The result of burning of explosives is always the production of quantities of very poisonous fumes of carbon monoxide and nitrogen peroxide, as explained in Mr. Mann's report. The disastrous accident at the Mount Charlotte mine, at Kalgoorlie, by which six men lost their lives, shows how deadly these gases may be. Similar accidents are on record elsewhere, and the moral to be drawn from them is that all places in which shots have been fired must be thoroughly cleared out by a current of air before they are fit for men to resume work.

It is worth noting that, according to our knowledge of the decomposition of nitroglycerine explosives, the formation of peroxide of nitrogen is accompanied by that of carbon monoxide; so that when the one gas is present the other should be also. It is commonly stated that a certain amount of carbon monoxide is found even in complete explosions of nitroglycerine compounds, while no mention is made of the peroxide of nitrogen; but the equations given by authorities on the subject all involve the simultaneous presence of both gases, the oxide of nitrogen in greater volume than the carbon monoxide. Yet in analysis quoted in the Transvaal Commission's report, and also by Haldane, Martin and Thomas, carbon monoxide is often reported without any corresponding peroxide of nitrogen. In the tests carried out by Mr. Mann, both gases were uniformly absent, so far as any measurable quantity was concerned, except when some blasting gelatine had been deliberately burned, though traces of nitrogen peroxide could be detected qualitatively in several cases by the very delicate iodide-of-starch test. In wet workings it may be that the very soluble fumes of nitrogen oxides are rapidly absorbed by the moisture present, while the slightly soluble carbon monoxide remains in the air. This may be the explanation of the accident to Owen Hughes, at the Turn of the Tide mine, who appears, according to the medical evidence, to have been poisoned by oxides of carbon without being affected by the oxides of nitrogen. We cannot, however, feel at all certain of the diagnoses that have been made in cases of fumes poisoning, as our inquiries rendered it very evident that hardly any of the medical men examined had given special attention to the nature of the gases causing accidents, or had been at pains to ascertain whether nitrogen oxides or those of carbon, or both, were responsible for them.

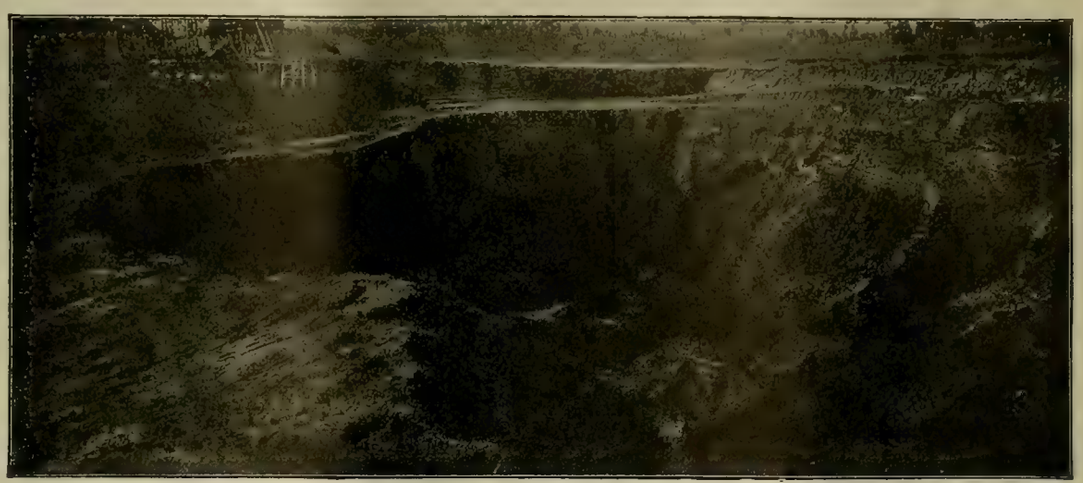
Quarrying Iron Ore.

Written for the MINING AND SCIENTIFIC PRESS.

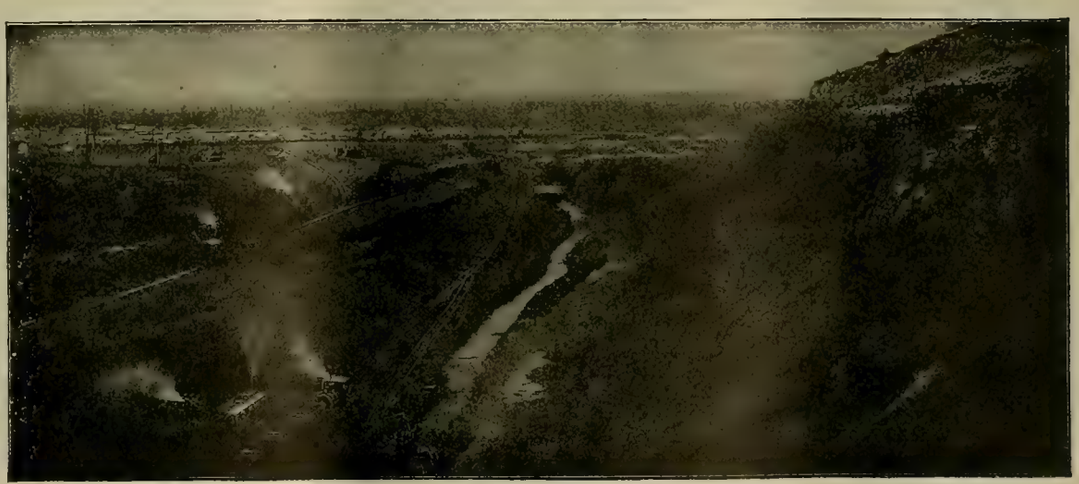
Vastly different in appearance from the drift mines of California, the quartz mines of Colorado, or the copper mines of Montana, are the iron mines of Minnesota. Of the latter, there are several kinds and modes. In the surface pit a steam shovel is the main factor in results, it being an open cut like ordinary railroad work. In the underground iron mines is the nearest approach to gold or copper workings; the expense of securing the ore is considerably more, but as it requires extended admixture of different iron ores to make the required quality of iron, and as some of the requisite ore can only be secured from lower strata, the extra expense becomes necessary. Another form of iron ore mining is the milling, or deep, open pit. Manifestly the cheapest mine to operate is the surface pit, of which the Missabe Mountain mine, Mesaba range, Minnesota, furnishes a good illustration. As shown, the ore is simply loosened up, lifted on cars by steam shovels and started for the smelter, there to be converted into steel. In an open pit mine the surface is first stripped of its soil, which may be 2 or 50 feet in depth. The accompanying illustration of an open pit at the Auburn mine, on the Mesaba range, gives a better idea of the appearance of such a mine than any written description. This style of mining is mostly in vogue where the ore is in gigantic pockets. It sometimes occurs that a costly pumping plant must be provided. Where depth is attained and the ore vein is followed, such a mine as that depicted develops into an underground mine, with its customary shafts and levels.

Mining and scientific progress is grandly exemplified in the case of the Lake Superior iron mines. Not only is this shown in the system of mining, but to even a greater extent in the handling of the ore. A recent achievement in that line was the loading of a steamer—the Augustus B. Wolvin—at the Great Northern docks, Allouez bay, with 10,245 tons of ore in eighty-nine minutes. That ore was carried in that steamer to Conneaut, Ohio, at a cost of less than 75 cents per ton.

From the Lake Superior iron ore region, of which the Mesaba range is so prominent a part, there have been shipped over 250,000,000 tons of ore. About 80% of America's iron ores come from this region, and about that percentage of the country's iron and steel is made from those ores. This represents a growth of fifty-two years. In 1853 seventy tons of Lake Superior iron ore were used in a Pennsylvania blast furnace. Fourteen years after the Bessemer process (to which the Lake superior ore is particularly adapted) caused the Lake Superior iron ore mining industry to begin to assume its present gigantic proportions. There are now a score of mines there, each of which annually produces more than 500,000 tons of ore.



Milling Pit, Auburn Mine, Mesaba Range, Minn.



Missabe Mountain Mine, Mesaba Range, Minn.

THE PROSPECTOR.

The green-stained rock from Pine Nut range, Lyon county, Nevada, is feldspar porphyry, with incrusting stains of malachite (copper carbonate) and chrysocolla (copper silicate). Very low grade. The white rock is sericite schist.

Three packages of rocks received from Burnt Ranch, Cal., are determined as follows: No. 13, felsite, with finely disseminated pyrite. No. 14, a feldspathic rock containing several per cent of copper sulphide (chalcopyrite). One side is incrusted with calcium sulphate (gypsum). No. 15 is similar to No. 14, but also contains epidote (a greenish yellow mineral). No. 16 is from the croppings of a vein or deposit of iron and copper ore. The green mineral is malachite (copper carbonate). No. 17 is a much altered greenstone, probably diorite. No. 18 is probably the same kind of rock, occurring nearer the surface. This may prospect in gold. No. 22 is diorite. No. 23 is feldspar porphyry. No. 24 is diorite. No. 25 is also greenstone, probably diorite.

The samples from Hailey, Idaho, are: No. 1, a sulphide ore containing lead, iron, zinc, arsenic, a little copper, probably gold and silver. It is a very complex ore, requiring smelting, or concentration of the various minerals by means of magnetic separator. The gangue is quartz. No. 2 is gray limestone, one piece of which shows iron oxide.

The rocks from Goldfield, Nev., are as follows: No. 25, a type of diabase. No. 26 is chiefly calcium carbonate. No. 27 is rhyolite, with porphyritic feldspars and quartz blebs. No. 28, rhyolite. No. 29, porphyrite. No. 30, quartzite. No. 31 is basaltic rock. No. 32, rhyolite of fine and even texture. No. 33, diorite containing some iron sulphide. This rock is older than the volcanic rocks previously described, and probably occurs in the underlying formation or is from another district. No. 34, tuff. No. 35, similar to No. 32, but somewhat stained with iron oxide.

The rock from Unuk River, B. C., is diorite and contains disseminated copper sulphide and pyrite.

The slaty mineral from Corning, Tehama county, Cal., is hematite, with some earthy impurities. It is an ore of iron and should be tested as to its value by those engaged in the industry of iron making. At present no iron mines are being worked in California, although there are large deposits of the ore in various localities.

The rock sample from Lamb Creek, Idaho, is amphibole rock—consisting largely of hornblende. It also contains iron and copper sulphide.

The rock from Harrington, Ariz., is quartz, with bright, glistening specular iron (variety of hematite). This was probably mistaken for galena. The sample contains no lead, but should be carefully tried for gold.

The Prospecting department of this paper makes no analyses nor assays of rocks or ores—simply classifies rocks and determines minerals.

Placer Mining in Alaska.*

NUMBER VIII.

HOISTING.—For hoisting and conveying, say to a distance not exceeding 200 feet, the Dawson self-dumping carrier, with accompanying bucket, cables, etc., and steam hoist, must be used in order that the most economical work per man employed can be done. This device, which is shown in Fig. 16, is without doubt the best system of handling gravel from a shaft of shallow depth now in use in the Northwest. It is strong and compact, and is simple in operation. Those parts which by their position receive the most strain and jar can be made sufficiently durable to withstand hard usage.

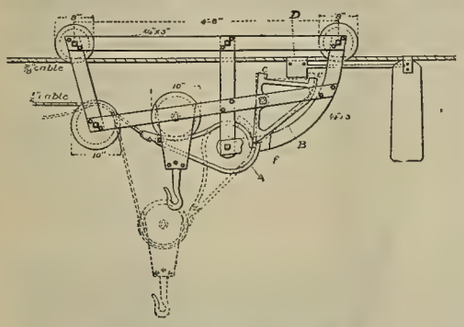


Fig. 16.—Self-Dumping Carrier.

No springs are used in the construction for the reason that at low temperature, say 40° F. below zero, metals are very brittle, and the constant jar, a necessary accompaniment of the work of this apparatus, renders springs and any light metallic member unsafe.

As Fig. 16 shows clearly the construction of the carrier, only a few words need be said of its operations.

It may be stated that three distinct operations are accomplished, two of which are performed by the carrier, the third being effected by an auxiliary rope used in dumping the bucket. The first consists in engaging the bucket as it arrives from the shaft and carrying it to the dump box, the second in returning the bucket to the head of the shaft and there dropping it to the bottom. As the carrier returns down the ⅞-inch cable, the hook to which is attached the bucket occupies the position indicated by the solid line. The cam A lies horizontally and is held firmly in this position by the dog B, the weight of the bucket pressing the notch of the cam against the point of the dog f. When the carrier reaches the head of the shaft the end c of the dog strikes the block D and frees the point of the dog from the notch of the cam. The front of the cam now occupies the position indicated by the dotted line, and, as the bucket sinks into the shaft, is pressed against the block, since the carrier tends to move backward. Thus as the bucket sinks with the hook on the ½-inch cable the carrier is held firm.

As the bucket rises from the shaft or pit the strain is toward the engine, and the lower en of the dog e still prevents the apparatus from movi .

When, however, the cam A by the up ard movement of the bucket reaches the horizontal position indicated by the solid lines, the point of the dog f jumps into the notch, lowering at the same time the point e which allows the carrier to move up the ⅞-inch conveying cable, and also once more secures the cam in its horizontal position.

The block attached to the cable is held in a vertical position by a suspended log or block, which insures its engaging with the dog.

By this system of working, if the self-dumping rig handles 250 of the 30-pan buckets in ten hours or, roughly, 60 cubic yards, the plant will necessitate the employment of twelve men, namely, two firemen, one hoist man, one point man and seven men shoveling and wheeling, beside the foreman. The boiler used for generating the steam for points at night is used for running the hoist in the daytime. In running from fifteen to twenty points a night it will burn from one-half to one cord more. The total daily twenty-four hour expense can not be brought below $130 and will probably amount to $150. It is evident that with such a plant the tenor of the gravel must amount to at least $2.60 to the cubic yard to pay any profit at all, exclusive of washing in the spring, and should be 4 cents to the pan, or $5.20 to the yard, to pay a profit which compensates for operating in so remote and expensive a country. The cost of washing in the spring is in general from 50 cents to $1 per cubic yard.

The winter dumps are piled in a conical heap around the gin pole, to which the trolley cable of the self-dumper has been attached while the dumping is in progress. In laying out the space for the dump, the string of boxes in which the gravel is to be washed during the following spring is so laid that it will bisect the proposed cone, having its proper grade and length. When the spring opens the dump is easily shoveled into the boxes, from both sides, beginning at the lowest point and working upward. Boards are generally laid over the top of the boxes, and a portion of the gravel rests on these. The boards are taken off as the work of shoveling in progresses.

The expenses of winter work are much greater than those in summer, and the tenor of the gravel must in consequence be much higher. In the first place it is to be remembered that the gravel dumped in winter must be all rehandled in the spring. In thawing, also, the amount of steam used in winter is greater than in summer, and all pipes and hose conveying steam both above and underground must be coated with asbestos or other nonconducting material. On the other hand, labor is generally cheaper in winter than in summer, and the possibility of striking thawed streaks of ground is much less.

*Bulletin 263 U. S. Geological Survey.

SURFACE WATER may sometimes be kept out of the pit at the commencement of sinking a shaft through soil, decayed rock, or other loose material, by driving sheet piling, either of metal or wood, entirely around the excavation to bedrock or far enough into the ground to cut off the water percolating through it, thus forming a sort of coffer dam, from which the water may be removed. If the depth to bedrock is too great, then another means may be employed, but it will prove less effective—that of forepoling in the shaft—that is, driving lagging ahead of the work of excavation. This lagging must be of sawed plank and set as closely together as possible. It is not calculated to hold back the water, but to keep the soft ground back in place so that the miners may rapidly remove that from the bottom of the excavation. The water must in this case be removed by a pump or otherwise. Some difficult sinking has been accomplished by means of two shafts sunk close together.

The Nissen Stamp.

The Nissen stamp is an individual mortar stamp with circular screen surface. In South Africa coarse stamp mill crushing is deemed desirable because of the increased capacity per stamp and consequent saving of power and interest on the investment. There it is followed by regrinding in mills. Elspass mills, tube mills and Chilian mills are used for regrinding. The circular screen of the Nissen stamp, among other features, is intended to increase the capacity of the stamp. The splash in a Nissen stamp, striking the screen at right angles because of its being circular, is with the intent of allowing more ore to go through the screen each splash than ordinarily.

Fewer slimes is another essential. Where the splash of the water carrying the ore with it always strikes the screen at right angles, and thus gives the particles of ore crushed small enough to pass the screen better opportunity to do so, and the ore thus being able to escape from the mortar more easily, fewer slimes are made. This is especially a desirable feature where an ore is to be stamped to pass a certain sized screen for amalgamation purposes, and to be followed by concentration or cyaniding, or both, in either case the slimes being undesirable and increasing the cost of operation. Many mills in the western part of the United States have found this to be the case.

FIG. 1.

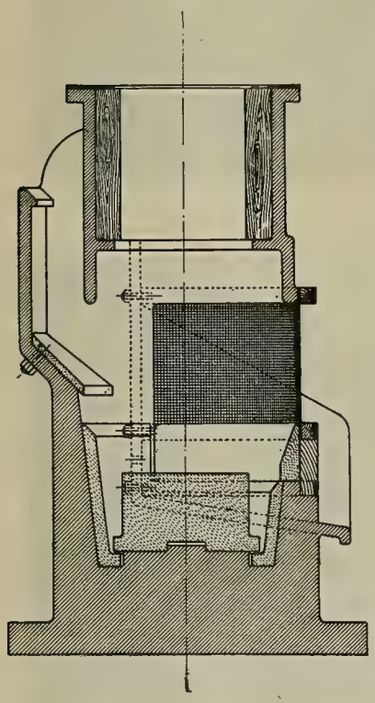

FIG. 2.

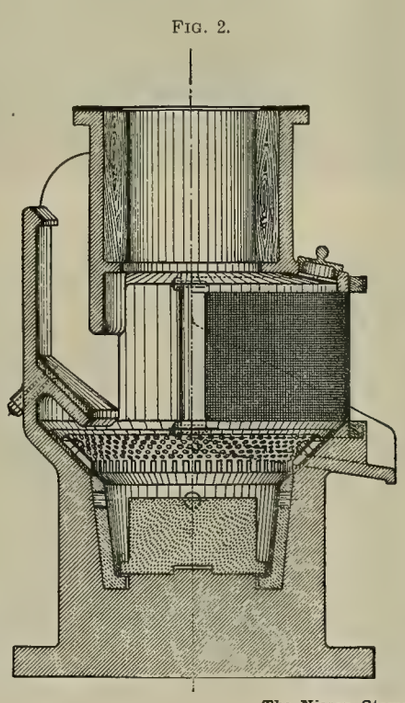

FIG. 3.

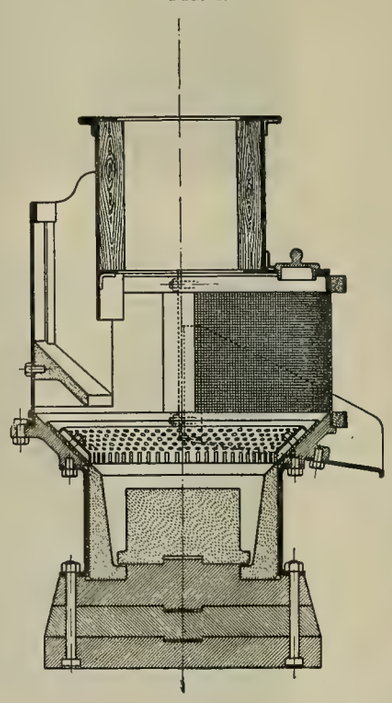

FIG. 4.

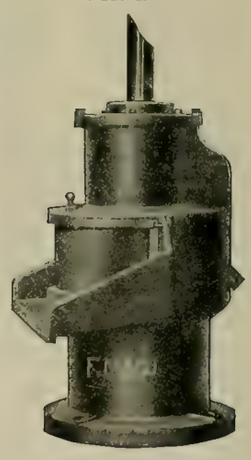

The Nissen Stamp.

The Nissen stamp is manufactured by Fairbanks, Morse & Co. in several styles of mortars to suit the particular requirements—as to discharge, size of the mortar and location of the amalgamation plates—that each individual mine has found best suited to their ores. It is primarily a circular mortar having a gravity stamp operated by the usual cam and tappet method, one stamp in each mortar.

Each Nissen stamp is intended to be a separate and complete stamp mill in itself. The mortar weighs one-third of that of an ordinary 5-stamp mortar. Each stamp can be hung up and the mortar cleaned separately.

The Nissen stamp chuck block mortar is shown in Fig. 1. General arrangement, height of discharge and other details are made in each case to suit the requirements of the mine. The Nissen mortar arranged for inside amalgamation is shown in Fig. 2. In many cases a sectionalized mortar for muleback transportation is necessary. The ease with which this can be arranged in the Nissen mortar is shown in Fig. 3. The general view of the Nissen individual mortar stamp in Fig. 4 shows the arrangement used in the Nissen stamp.

Fairbanks, Morse & Co. are the sole manufacturers of this stamp and assert that they have their plants running overtime supplying the demand that exists for this stamp and other of their mining and milling machinery.

MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

ARIZONA.

Cochise County.

The new mill of the Vanita M. Co., which is working the Pearce property below Benson, was stopped after running a few days, by the breaking of essential parts, and instead of repairing them it is said that the company will build a larger mill. The new mill is to be built at once, and will have double the capacity of the old one. Pumping machinery supplies water from the mine to run the entire plant.

Gila County.

(Special Correspondence).—Shipping is to be resumed from the Starlight mine of the Tri-Bullion Smelting & Development Co., in the Stanley Butte region, 8 miles south of San Carlos. Mining work was begun in January, 1903.

San Carlos, Oct. 2.

The Arizona Commercial Copper Co. is putting in a Sullivan diamond drill on the 300-foot level of the Copper Hill mine, near Globe. A strike of rich ore was recently reported to have been made on this level. On the Black Hawk mine crosscutting on the 200-foot level is in progress.——Superintendent F. M. White of the Warrior Copper Co. is shipping fourteen tons daily to the Old Dominion smelter.——Work is to be resumed on the Arizona-Colorado M. Co.'s property near Globe by Superintendent J. W. Banhauer. The shaft, now down 300 feet, is to be sunk to a depth of 500 feet and then a crosscut made to the main lead.——The Globe & Arizona Dev. Co. have driven the tunnel on the Black Oxide claim 480 feet and is in mineralized rock. The company is also sinking a shaft on its Limestone claim.

Graham County.

(Special Correspondence).—Rich silver ore is being shipped from the Commerce mine, 14 miles from Duncan. It is under the management of Arthur Murphy. The new strike was made at the bottom of a 200-foot shaft.

Work has been started on the Fraction claim, near Metcalf, by P. F. Crowley.——It is expected that the new converting plant of the Shannon Copper Co. will be in operation about the first of the year.

Mohave County.

W. B. Ridenour, of Hackberry, has relocated the Hackberry mine and intends to reopen it to the north of the deep shaft. The mine was opened to a depth of nearly 600 feet when owned by the Indian Queen Co.—— R. P. Wheeler, of Milwaukee, is at the Sun Cloud mine, where he will give a contract to sink 100 feet, a whim having been sent to the mine from Congress. The mine is on the Big Sandy, 4 miles south of Signal.

CALIFORNIA.

According to the report on mineral products of this State for 1904, prepared by L. E. Aubury, State Mineralogist, the total value of mineral substances produced in the State in 1904 was $43,778,348; that of 1903 was $37,759,040, an increase of $6,019,308. This is a greater increase than has been shown for many years past, the usual amount for the past ten years being about $2,000,000 a year. The largest increase for the year is in the gold output, which amounted to $3,000,000 above the yield of 1903. The total value of the metallic substances (including precious metals) for 1904 was $25,114,699, which includes gold, silver, pyrites, quicksilver, copper, lead, manganese, platinum and chrome. The silver is given in commercial value, or the amount received for it by producers. The total value of non-metallic substances was $2,131,369. These substances include borax, coal, mineral waters, salt, infusorial earth, gypsum magnesite, mineral paint, lithia-mica, fullers earth, mica, soda, tourmaline and other gems. The total value of the hydrocarbons and gases was $9,257,434, an increase of $1,312,161. The hydrocarbons and gases include asphalt, bituminous rock, natural gas and petroleum. The petroleum price is the average free on board at wells or stations in each county. The number of barrels of oil produced was 29,736,003, valued at $8,317,809, as against 24,340,839 barrels in 1903, valued at $7,313,271. The increase in asphalt is also very large for the year, it now being made in the refining of California heavy oils. The total value of structural material was $7,274,846, an increase of $366,383 over the previous year. These materials include brick and pottery clays, Portland cement, lime and limestone, macadam, rubble and concrete, paving blocks, marble, granite, sandstone, serpentine, slate, glass sand and soapstone. The relative value of the principal minerals of the State is as follows: Gold, petroleum, copper, clays and their products, cement, rubble, quicksilver. The amount and value of each of the mineral substances is tabulated by the State Mineralogist as follows:

Asbestos, tons	10	$162
Asphalt, tons	56,187	672,910
Bismuth, tons	20	2,400
Bituminous rock, tons	45,280	175,680
Borax (crude), tons	45,647	698,310
Cement, bbls	969,538	1,539,807
Chrome, tons	123	1,845
Clays (brick), M	281,750	1,994,740
Clays (pottery), tons	84,149	81,952
Coal, tons	79,062	376,494
Copper, pounds	29,974,154	3,969,995
Fuller's earth, tons	500	9,500
Glass sand, tons	10,004	12,276
Gold	.....	19,109,600
Granite, cubic feet	520,687	467,472
Infusorial earth, tons	6,950	112,282
Gypsum, tons	8,350	56,562
Lead, pounds	124,000	5,270
Lithia-mica, tons	641	25,000
Lime, bbls	579,451	571,749
Limestone, tons	40,207	87,207
Macadam, tons	532,690	414,668
Manganese, tons	60	900
Magnesite (crude) tons	2,850	9,298
Marble, cubic feet	56,401	94,208
Mica, tons	50	3,000
Mineral paint, tons	270	1,985
Mineral water, gallons	2,430,320	406,916
Natural gas, M cubic feet	144,437	91,035
Paving blocks, M	3,977	161,752
Petroleum, bbls	29,736,003	8,317,809
Platinum	.....	1,849
Pyrites, tons	15,043	62,992
Quicksilver, flasks	28,876	1,086,323
Rubble, tons	1,764,208	1,227,209
Salt, tons	95,968	187,300
Sandstone, cubic feet	363,487	567,181
Serpentine, cubic feet	200	2,310
Soda, tons	12,000	18,000
Silver (com. value)	.....	873,525
Slate, squares	6,000	50,000
Soapstone, tons	228	2,316
Tourmaline	.....	65,000
Other gems	.....	71,000
Total valuation		$43,778,348

Amador County.

Electric is being substituted for water power at the Argonaut mine, near Jackson. The mine, mill and rock breaker are to be run by electricity.——The Climax new 10-stamp mill, near Jackson, is to be ready within a month. A 4000-foot pipe line and 2 miles of ditches have been put in.

Butte County.

The Boston & California Dredging Co., now operating three dredgers; the Boston & Oroville M. Co., now operating three dredgers and constructing another; the Bear River M. Co., now constructing one dredger, and the Oroville Gold Dredging & Exploration Co., now operating two dredgers, are included in the new Oroville Dredging Co., Ltd., with W. P. Hammon as manager. The properties include 3000 acres of proven ground, of which 300 acres have been mined. Of the 3000 acres, 2000 are on Feather river and the remainder on Bear river, between Yuba and Placer counties. These properties include eight dredgers in operation and two being built. The properties of the Yuba Con. Gold Fields Co. are not included in the new company.

Calaveras County.

The Angels quartz mine has started their quartz mill at Angels.——Superintendent Alex. Chalmers, of the Lightner mine at Angels, has struck on the 700-foot level a 30-foot vein, which shows the main ore body worked on the upper levels has been reached on the lowest workings.——Sinking is being continued at the Cordelia mine at Murphys.

El Dorado County.

The Sunrise mine, near Kelsey, is to be reopened and worked by Colorado capitalists. G. C. Ranney is arranging for lumber with which to rebuild the mill.

Inyo County.

Coso camp is 33 miles from Keeler, the terminus of the Carson & Colorado Railroad. In this district G. D. James of Reno, Nev., recently examined the Green Bay, Calumet, Chicago, Delaney No. 1, Delaney No. 2, Delaney No. 3 and the Wisconsin properties and found a mineral zone 150 feet in width showing values of $3 to $10 gold per ton. The belt appears to be valuable for cyaniding. In the Modoc district, along the eastern foothills of the Argus range and 20 miles east of Coso, the veins appear to be narrower and encased in granite and porphyry walls, the granite predominating. Among the properties examined were the Clementina, Isabella, New Year, New Britain, Willie, Lost Hope and Bordel. The veins are about 2½ feet wide, as shown by a 12-foot shaft on the Isabella, a 30-foot crosscut tunnel on the New Year, with drifts each way, and on the Clementina a drift 60 feet in length. The values are much higher. Modoc camp is across the Panamint valley and 18 miles from the old Ballarat camp.

Kern County.

At a meeting of representatives of all the companies in the Independent Oil Producers' Agency of Kern county at Bakersfield, Oct. 4, preliminary plans were laid for uniting all the independent companies into one large company, to which all the oil land now in the possession of the independent producers will be deeded. Preliminary plans were also laid for the construction of two 1,000,000-barrel reservoirs for the storing of oil. The object of the independents is to compete with the Associated, to which company the agency is now bound under contract to deliver oil at the wells at 18 cents a barrel. The contract will be completed in a few months, and the evident intention of the independents is to be prepared at the fulfillment of the contract to market the independent oil at a satisfactory figure. Under present conditions the greater portion of the independent oil is being delivered to the large companies at a price that means little if any profit to the producers, and the preliminary action of to-day means the beginning of a last determined effort on the part of the independents to throw off the burden of the big corporations. This is but a continuation of the first united move on the part of the independent producers a year ago, and has for its object the formation of a company organized much on the plan of the Associated, and which it is intended shall embrace all the independent companies in the Kern River, the McKittrick, the Sunset and the Coalinga fields. If the plans of the producers are carried out, the properties of the independent companies will be deeded to the proposed company, and will be paid for in stock issued by the company. By this means the new company will hold in fee simple all the oil properties in the San Joaquin valley, with the exception of the holdings of the railroads, the Associated Oil Company and the Union Oil Company, and will be in a position to take steps toward transporting independent oil by means of an independent pipe line to tidewater and the market.

The Big Four M. Co. has driven its development and drainage tunnel, near Havilah, 800 feet.

Modoc County.

(Special Correspondence). — Considerable excitement has been caused by reports of gold discoveries west of Fort Bidwell. The camp is 12 miles from Fort Bidwell, in Surprise valley, and 6 miles from New Pine creek, in Goose Lake valley. The mails go up from Reno by rail to Madeline, 144 miles, and thence by stage to Alturas, the county seat of Modoc county, 35 miles. From Alturas there are two stage lines—one through Surprise valley to Fort Bidwell, the other through Goose Lake valley to New Pine Creek, which is on the Oregon-California line, half the town being in one State and half in the other. The distance either way from Alturas is 45 miles, making the total distance from Reno 230 miles. It may also be reached via Redding. The discoveries have all been made in the Warner Range, which runs north and south between Goose Lake on the west and Surprise valley on the east. They prove that the country is mineralized and worth prospecting. The rocks are eruptive and no sedimentaries have been found. The camp is 86 miles from the Nevada-California-Oregon narrow gauge railroad at Nevadaline, and it will cost $20 a ton to haul the ore by wagon to the railroad.

The Plummer-Reid-Wade mine, near the summit, has been bonded by B. Levison of Elizabeth, N. J., who intends to develop it. It is said to be a large low-grade proposition. Ore has been taken out of the Syphreth and Kafeder claims. No reliable assay reports have been made as yet, and, while the country is undoubtedly mineralized, yet the extravagant reports of bonanzas should not form the basis for investment without investigation. Modoc county consists of a succession of valleys, formerly inland lakes, following one another through the country from north to south. Goose lake, Tule lake and lakes in Surprise valley are remnants of these former lakes. These valleys are connected by narrow rocky canyons, or are separated merely by low volcanic ridges, and are bordered by bluffs of volcanic rock, marking the limits of former lava flows. Prospecting has been difficult on account of the lava coverings. Warner's Range is in several places over 8000 feet in height and snow prevents winter access. Water is plenty in the range, though scarce in some of the surrounding country.

Alturas, Oct. 2.

Nevada County.

R. J. Simmons is opening up the Eclipse mine on Gold Flat, near Nevada City. The old shaft, which is 150 feet deep, will be cleaned out and retimbered. —— The new hoisting plant on the Badger Hill drift mine, near Nevada City, has been completed and sinking is now under way. The vertical shaft will be sunk to a depth of 150 feet. —— The Junction mine at North San Juan has been bonded to R. W. Correll of San Francisco for $60,000.

Placer County.

The Black Canyon mine, near Westville, has closed down.—— The Polar Star at Dutch Flat is to be reopened.

The drill used in boring the air shaft in the Hidden Treasure mine, at Bullion, has broken through and the air can now go through the shaft, but there is still 70 feet to finish, as the hole from the drill is only a small one.——The Reed and White placer mines and ditches have been leased to F. G. Albinos and M. Toy of Michigan Bluff by J. D. Meredith.——J. S. Mills is sinking the main shaft of the Dairy Farm Extension mine, near Lincoln.

Siskiyou County.

The C. A. Patterson Co., operating the Eliza mine, near Yreka, and putting up a 12-stamp mill, has secured the Judge Spencer mine, adjoining.

Sonoma County.

Arrangements are being made at the Socrates quicksilver mine at Pine Flat to operate all of the machinery by electricity, as well as to light the shafts and tunnels. A dam, 35 feet high, has been made across Sulphur creek, opposite Dewey's mill. At present steam is being used as power. The company has built a 50-ton ore furnace, which will be fired about October 15. November 15 the first charge of ore will be placed in the furnace.

Tuolumne County.

E. C. Loftus, superintendent of the Santa Ysabel mine, near Stent, is putting in concentrators. All is in readiness to start twenty of the mill's forty stamps dropping as soon as power comes on. Ore has been blocked out in Nos. 2, 4 and 6 levels of the main 3-compartment shaft, while sinking in this, which has been temporarily suspended at the 800-foot mark, will be resumed and continued to a depth of 1500 feet.——Retimbering the shaft and other improvement work is being done on the Goldwin mine, near Tuolumne.——The old pipe line at the App mine, near Quartz, is being replaced by a new one. ——Superintendent A. W. Bryant of the Prudhomme, near Carters, says that work on the property will be resumed in the spring.——A new tunnel will be started on the Sunnyside mine, near Tuolumne, that will tap the vein 200 feet deeper than the old working adit.—— The incline shaft on the Confidence mine, at Confidence, is down 900 feet. Drifting is being done from the bottom in an endeavor to pick up the pay shoot found in the upper levels. The mill and cyanide plant are running steadily.

COLORADO.

(Special Correspondence).—The corner stone of the new hall at the State School of Mines was laid October 2. The money for the erection of this building was presented to the school by S. Guggenheim of the smelter trust. The school is at Golden.——The State Supreme Court handed down a decision in the flat tax question which means that the flat tax law must stand and that corporations will be assessed accordingly. It is believed that the case will be appealed to the U. S. Supreme Court for final decision, as it will make considerable difference with the firms doing business in the State.——It is encouraging to note the difference between now and this time last year. In several camps visited during the past few months the report is to the effect that there is a scarcity of good miners. There are plenty of men running around the towns saying "there is nothing doing," but according to the operators in the various districts there is plenty of work for good men. A few days ago in Leadville one of the operators stated that he had been for several days trying to get five miners and had not been able to secure them. This seems to be the report generally over the State. The summer months have seen a good trade among the machinery and supply houses of this city and for some time to come the

trade should be A1, as in many camps they are now taking in supplies for the winter, especially in the more rugged and colder districts.

Denver, Oct. 2.

Boulder County.

After an inactivity of several years the Wano mine and mill at Jamestown are being renovated. The Monarch Consolidated Co. will begin operations. W. H. Davis, the company's chemist, reported that roasting and cyanide treatment are applicable to the ores of the Jamestown region. The capacity of the mill will be increased to meet the demands of the Wano mine. Rolls will be put in for crushing. No outside custom ore will be treated by the company. A six-pound solution of cyanide will be used and a direct oxidizing roast, such as was recently put in at Magnolia, will be employed.——The plans for the new mill are being drawn by Franz Cazin, of Denver. The mill is to be operated by a 500 H. P. water plant and a 100 H. P. steam plant.

There are said to be 400 men working in tungsten producing mines, near Nederland. A recent shipment of 41,100 pounds of crude ore from Miller & Co. yielded 7475 pounds of tungsten, carrying 66.07% tungstic acid. The shaft is 30 feet deep.——The 15-stamp mill of the Boulder County mine is running continually.——Superintendent T. P. Oliver, of the Colorado Tungsten Co., is opening up good ore and shipping to the Boyd mill at Boulder.——F. Karstrom is shipping to the Boyd mill. ——The Nederland Tungsten Leasing Corporation is working the Illinois property of the Wolf Tongue M. Co. and have a tunnel in 80 feet. Several loads of fair tungsten ores were taken out of the surface workings of this lease.

Chaffee County.

(Special Correspondence).—F. G. Mitchell, manager of the Lost Canon Con. Deep Tunnel G. M. Co., is operating in Boswell gulch, 20 miles south from Leadville. The tunnel is now in 1100 feet and considerable drifting done on the vein. According to reports, the ore averages $20 per ton. The tunnel cuts the vein 600 feet under the surface. A mill will be built next spring.

Leadville, Oct. 2.

Clear Creek County.

The Gem Mines Co. has completed the new electric air compressor at the collar of the Gem shaft, near Idaho Springs. It will be driven by a 150 H. P. electric motor and will furnish air for ten drills. The plant will furnish power for twenty-five sets of leasers in the Gem and Freighters' Friend mines, besides furnishing power for the operations of the company in their lower levels.—— Wright, Lilly and associates of Colorado Springs intend to organize a new company on the Dubuque claims up Fall river from Idaho Springs and opposite the Lucania tunnel in which they are now interested. The property has been developed by an adit tunnel which is in 400 feet. A main tunnel will be driven to cut the different lodes.——I. N. Rogers and H. C. McCreery have sold the Refugee mine at the head of Hukill gulch to G. A. Starbird and E. S. Lewis of Denver.

At the Santiago mine, in East Argentine district, near Georgetown, after running the crosscut No. 5 over 600 feet the main vein was reached and drifting started. The width is 4 feet between walls, the pay streak carrying 18 inches of fine smelting ore. This point is 150 feet below No. 4 tunnel and 1100 feet below the crest of the hill. No. 4 tunnel is being driven on a 3-foot streak of ore. Manager Wm. Rogers is cutting an upraise above No. 3 and another above No. 2 tunnel. The mill at Georgetown, after being overhauled and adjusted, is handling forty tons every twenty hours, there being an interval of four hours each day when the electric power from the Georgetown plant, being otherwise engaged, is insufficient. The rock concentrates from three to seven tons into one after the smelting product has been sorted out, and contains in the crude from $8 to $20 per ton. The process employed is crushers, rolls, Huntington grinders, jigs and tables. It is probable that the finer products, slimes, etc., will be cyanided later on. The mill is shipping from one to two cars of concentrates per week and three cars of selected ore per month. The entire output of the mine is hauled in wagons 7½ miles to the ore bins of the mill at a cost of $1.80 per ton, each wagon carrying from four and a half to five tons at a load.

The Consolidated Park M. Co. has been formed to work the Park claims on Seaton mountain, near Idaho Springs, under the direction of J. J. May. An electric motor to run an air compressor is to be put in as soon as machine drills can be used to advantage.——Reports come from Empire of two important strikes in the Dailey district, one in the tunnel being driven by the Red Mountain & Mad Creek M. Co., of which J. D. Williamson of Denver is president. The other strike is in Horseshoe basin.

Superintendent F. M. Tucker, of the Krupps M. Co., operating claims on Columbia mountain, near Empire, reports breaking into a 3-foot vein of high-grade silver-lead ore, running high in lead and carrying good values in gold and silver.

Gilpin County.

The stone foundation, being built on the Evergreen property in Apex, is completed and work will be commenced on the 60x100-foot shaft house which is to be built near the mouth of the 500-foot tunnel the company has been driving. Work on the tunnel is to be abandoned as soon as sinking is commenced.——Work has been resumed on the Ætna property in Nevadaville. New machinery has been put in. Work will be pushed in the 600 crosscut north at the 200 level. John Simmons has charge.

F. H. Owen of Central City has resumed operations on the Review mine, on Winnebago hill, and is stoping on the 200-foot east level. The property is owned by N. D. Owen of Denver. The main shaft is down 460 feet.—— Superintendent Frank Paxton, of the Russell M. Co., reports that they have completed retimbering the No. 4 shaft on the West Pewabic property from top to bottom, a depth of 180 feet. Leasers are at work in the lower levels.——J. J. Elliott of Denver intends starting the Springdale or Gold Rock property in Russell district, under a lease and bond. The main shaft is down 600 feet.

Gunnison County.

C. Skinner is superintending work on the Volunteer mine, near Pitkin. The winze is being unwatered preparatory to starting development work.——The Ben Franklin group, near Pitkin, has been leased to A. B. Clark, who intends working it.

Hinsdale County.

It is expected that the Hanna mill, at Capitol City, will be completed by Nov. 1.

Lake County.

A good body of ore has been opened at the 900-foot level of the Evelyn, Graham park, near Leadville. The shaft on the property is 1200 feet deep.——Machinery is being placed on the Little Nell claim on the crest of Carbonate hill by Lomeister and associates, of Leadville, and when in running order work will be carried on at the bottom levels. At present prospect work is being done at the 500-foot level to try to locate a shoot of ore. ——The Long & Derry property, near Leadville, will again be worked. C. Taylor, of Leadville, is interested.

After being idle for several months the Adelaide, one of the oldest mines near Leadville, has started hoisting. The plant is being operated for N. West of Denver by John McAlister. The water has been pumped out. Work is to be done at the bottom level, 380 feet below the surface, where drifting is being carried on.——The Hub mine, near the Adelaide, is idle.——A little sulphide is being taken out of the No. 1 shaft of the Ohio & Leadville Co.'s Ollie Reed mines. They are prospecting at the fourth level. A diamond drill has been at work for some time in the No. 2 shaft. It has gone down at the rate of 12 feet a day, and is now 250 feet below the bottom of the 350-foot shaft.——The Mastiff M. Co., which has a lease on the Humboldt mine at Adelaide Park, is taking out fifteen tons a day of low-grade ore. Stoping is being carried on at the 375-foot level.

San Juan County.

The Sultan Mountain M. Co., operating claims on Sultan mountain, near Silverton, have begun a winter's campaign. They are running a crosscut tunnel on the Junior Warden vein to cut the Molas lead, and a contract of 400 feet has just been completed by Jesse Herr & Co. of Silverton. An additional 100 feet is to be run under contract by Olsen Bros., and when this contract is completed the breast of the tunnel will have been carried to within 300 feet of the objective point, at a depth of 150 feet below the old workings of the mine and 250 feet below the surface.

Summit County.

The stockholders of the Senator Gold M. Co. have voted to raise $30,000 for further development work by issuing gold bonds on the property. The property is on North Star mountain, 10 miles south from Breckenridge, and is developed by a crosscut tunnel which has cut veins carrying iron and copper sulphide ore with values in gold and silver. The property is equipped with a compressor, drill plant and buildings.

The Old Union M. & M. Co. of Breckenridge is running mine and mill to utmost capacity. Mill Superintendent C. Gilbert is shipping zinc products, which have found a market in Kansas. It can be safely stated at present that the Old Union is past the experimental stage, and from now on will be listed among the steady producing and dividend paying enterprises of the district.——Work has been resumed by the Rothschild Tunnel Co. on its bore at Argentine. Driving another 2000 feet is in charge of Thomas Webb.

In experimenting with the black sand in the Banner placer hydraulic works with wooden riffles, the value of the sand saved is 8.39 ounces in gold, and with steel riffles after passing the wooden riffles the value is $17. This shows a great value in black sand, of which there are large quantities, and all has heretofore gone to waste in placer mining.——J. H. Myers states that the King Solomon Mining Syndicate has been able to interest capital in the mineral fields near Montezuma, and they will soon have a mill running at the mouth of the Lenaway tunnel.

Teller County.

The mill of the Little Giant M. & M. Co. in Pony gulch, near Cripple Creek, is finished. It is calculated that the mill will be capable of handling 150 tons of low-grade ore daily, ore from surrounding properties as well as that of the company being desired for treatment.—— Operations have been resumed at the Homestake mill, on Ironclad hill, with S. M. Downs of Cripple Creek in charge.

The United States Reduction & Refining Co., operating the Standard plant at Colorado City, will shortly build a tailing cyanide plant.——Ore has been struck by the Equity M. Co. in its exploration on the second level of the New Discovery property, on the summit of Mineral hill, 1 mile north of Cripple Creek.——The Laura Lee on Mineral hill has been leased by an Eastern company and it is proposed to sink a shaft to the 1000-foot level and cut the cap rock which is believed to cover the hill. The shaft is down 400 feet.——In the Ruby mine on Bull hill, near Victor, prospecting is under the direction of the Merger M. Co.

The total output and value of Cripple Creek ore for September were:

	Tons.	Average Value.	Total Value.
Sioux Falls	1,200	$ 2 50	$ 3,000
Anaconda	2,550	7 00	17,850
Los Angeles	640	4 50	2,800
Wild Horse	1,200	6 50	7,800
Santa Rita	450	8 00	3,600
Smelters	9,500	60 00	570,000
U. S. R. and R.	25,000	30 00	750,000
Dorcas	3,300	32 50	107,250
Portland	7,500	28 00	210,000
Economic	6,000	28 00	174,000
Totals	57,340	.....	$1,846,300

Ore is being broken in the Midway mine, between Ironclad and Bull hills, Cripple Creek, at a depth of 186 feet. Exploration at a depth of 1000 feet in the Anaconda mine of Gold hill has shown ore. In reaching the 1000-foot point, a winze was started from the tunnel level, which has a depth of 600 feet and continued for 400 feet.

The Huntington mill, on the Mohawk Belle and Twin Sisters claims, between Raven and Bull hills, near Cripple Creek, is handling ten tons of ore a day. The plant is being operated by Carrington & Epy.——Ore running $40 per ton is being shipped from the Gregory mine at Cripple Creek.

A strike has been made in the Black Diamond on Tenderfoot hill, near Cripple Creek. Prospecting began in a 120-foot shaft.

IDAHO.

Owyhee County.

W. F. Sommercamp has organized the Potosi M. Co., which has taken over the Home and Potosi mines at Silver City. A hoist is to be put on the Potosi, on which a shaft was sunk several years ago, to a depth of 240 feet. The Home mine is on the same vein, adjoining the north end line of the Potosi.——The mill of the Addie M. & M. Co., at Silver City, has been started under the direction of Arthur Knapp. Amalgamating pans have been put in and amalgamating is done in the batteries, the pulp being elevated back and run through the battery twice before going through the pans.

Shoshone County.

The Snowstorm mine, near Mullan, is shipping 300 tons of ore daily. This is said to be the only copper mine in the Cœur d'Alenes that is producing at the present time.——John Newbury & Son are driving a crosscut on the Fanny Gremm, a property east and adjoining the You Like and the Midnight, near Mullan.

Washington County.

Work with the Landore smelter, owned by the Ladd Metals Co., has been steady since blowing in the reverberatory furnace. The plant is giving satisfaction. It has a capacity of fifty tons daily. Coke has been hauled regularly, so that the management has a good supply of fuel on hand.

MICHIGAN.

Houghton County.

Superintendent Edwards of the Tecumseh states that the drill at the second location has cut the Kearsarge lode at a depth of 185 feet and that drilling has been continued until both walls of the lode have been determined, together with their copper contents. The core that was extracted from the lode shows the same state of mineralization as that discovered in the other hole. Machinery is being moved to the location. Work will be started on the shaft as soon as possible, as sufficient development work has been done to assure the management that the lode exists on the location in the same state of mineralization as that of the first.

MONTANA.

Granite County.

D. T. Conkling and M. L. Bashor have leased from Gannon & Neu the Oro y Plata placer mines near the mouth of Henderson gulch, near Philipsburg. Associated with them is John Brasslin. While good weather lasts the lessees will prospect and make ready for work in the spring.

Silver Bow County.

(Special Correspondence).—Another section of the Butte copper district likely to rival both the old portions and the new country in north Butte lies south of the Pennsylvania mine. A scheme is on foot for the consolidation under one big company of a number of the best of these producing mines.——The Mountain View mine of the Boston & Montana Co. is in continuous operation and yielding 20,000 tons of ore each month. The Mountain View has been equipped with a new hoisting engine capable of working to a depth of 500 feet. A new hoisting engine has been ordered for the new four-compartment shaft that is now down 500 feet on the Leonard mine of the Boston & Montana Co. From the 1200-level of the mine another force is raising to connect with the opening from the surface. A new surface plant is being built, and will include a steel gallows frame 140 feet high and new ore bins 150 feet long. The shaft will be equipped with shaft dumping skips.——The Columbia mine in the Lowland district, 18 miles northeast of Butte, is being worked by leasers who are shipping to the Butte smelters.

Butte, Oct. 2.

The Butte Miner reports that the big concrete stack of the Butte reduction works, 352 feet and 7 inches high, has been finished after four months' work. In its building were used 60 tons of "T" steel, 1500 barrels of Portland cement, 1400 tons of sand. The weight of the chimney, inclusive of its concrete base and slag foundation, is 15,275 tons. The stack has a diameter of 18 feet, and rests on a concrete base of 1806 feet. This base stands on a slag foundation designed by James Doull, of the Butte reduction works, and is put into place under his supervision. This foundation was originally intended for a brick stack of the same internal dimensions as the present concrete stack. The outside diameter of the base of the chimney is 21 feet. For the foundation the ground was excavated to a depth of 7 feet, the formation of ground being a natural washed sand deposit. Into this excavation a box was made of cast iron plates 100 feet square and 3 feet deep. Into this box was poured molten slag. The foundation was built up by a series of these slag blocks 3 feet high, each block being stepped in from the outer edges of the one below 3⅓ feet, there being six of these blocks, making the slag foundation 18 feet in depth and 66⅔ feet square on its top surface. While the molten slag was being poured into the boxes, layers of steel wire rope, chain and T rail were sewed horizontally through each block, and standing vertically through these blocks of slag and projecting out of top of slag foundation and into the stack foundation base were 70 tons of scrap iron and steel. On top of this foundation was built the foundation of the chimney. This foundation consisted of a solid block of concrete 42½ feet square and 5 feet high at its sides and 8½ feet high in the center, the top of this block being shaped like the frustum of a pyramid. Horizontally through this block of concrete was laid four layers of 1¼x1¼-inch T iron, two layers being laid parallel with the sides of block and two layers diagonal. Into this network was placed vertically and in a circle corresponding to the size of the chimney

500 bars of 1¼x1¼-inch T steel, these bars being all bent outwardly at their lower ends. From the base to the top rings of 1x1-inch T iron were laid horizontally. For the first 21 feet of height of the chimney the walls are 18 inches in thickness and in these walls are the two inlets to the chimney, one on each side, each opening 8x17 feet. On top of the 18-inch wall the double shell of the chimney is placed, the outer shell being 9 inches thick, the inner shell 5 inches thick, these shells being separated by a 4-inch space, the air space at the bottom being connected to the atmosphere through the outer shell by portholes. The inside shell extends up to 101½ feet above the base, and the outer shell is offset over the inner shell, the air space being left entirely open on the inner side of the chimney and the inner shell free from the outer shell at the top. The outer shell is then carried 7 inches thick to the top of the chimney. The building of the stack has been rapid, 30 feet of height being attained per week. Main dust chambers to connect with the stack will be 360 feet long, 225 feet being 60 feet in width, while the remaining 105 feet will be 80 feet wide. They will be 30 feet in height. The chambers are being built of structural steel, with sheet steel roof and brick walls. Every consideration is given the welfare of the men employed in connection with the flues, the chambers being built on slag piers with transverse ducts permitting free circulation of air. Auxiliary dust chambers connecting with the calcine chambers will communicate with the main dust chamber. A steel converter building, which will accommodate two converter stands, is being built. This plant will be large enough for three converter stands if necessary. Two new matte furnaces, 20x60 feet, are being installed with 600 H. P. boilers, the waste gases of which will be utilized in the matte reduction.

NEVADA.

Esmeralda County.

The Goldfield News reports that for the week ending Sept. 28, 2340 tons of ore, having a value of $320,132, were consigned to the local mills or were shipped out over the railroad to the smelters. No returns were received from the Goldfield R. Co., as the Frank mill is closed down temporarily pending the arrival of an automatic sampler.——The plant of the American R. & M. Co., which was started up the first time a few days since, has as yet handled but a small amount of ore.——During the period 200 tons of ore, having an average value of $40 per ton, were treated at the Combination Co.'s mill; 693 tons of an average value of $104 per ton were treated at the plant of the Columbia Sampling & Ore Co., 50 tons—experimental—having an average value of $50 per ton at the plant of the American R. Co.; 290 tons of milling ore, having an average value of $40 per ton, and 152 tons of shipping ore, having an average value of $230 per ton at the plant of the New Western R. Co. At the latter plant there is now awaiting treatment 400 tons of milling ore and 500 tons of shipping ore. Aside from this there went out via the railway 28 cars containing 955 tons of ore of a gross value of $191,000. In connection with the railroad it can be stated that a flat rate of $17 per ton has been established on ore shipments, and that on first-class merchandise a rate of $3.80 per 100 pounds has been established; on other grades of merchandise a graduating scale has been adopted, these rates applying to goods en transit to and from San Francisco. The Wells Fargo Express Co. has also made a reduction since the advent of the railroad of $1.50 on the 100 pounds to all Pacific coast points.

Lincoln County.

The Old Colony M. Co. has ordered a 5-stamp mill and cyanide plant for the Yellowstone mine at Juniper Camp, near Searchlight. A 15 H. P. hoist has also been ordered. A new working shaft is to be started to go to the 500-foot station for the first stage. Levels will be run from this at every 100 feet. At the same time working shafts of similar depth are to be put down on the Bird and Golden Rod by the same company. Leonard Tobin is manager.——Work is to be resumed on the Old Roman mine near the Empire camp at Newberry mountain, near Searchlight. C. F. De Puy is manager. ——Superintendent A. A. Ross has resumed work in the Good Hope mine, near Searchlight.

Lyon County.

The Overland mine, in Silver City, has been sold for $25,000. It is understood that a shaft will be sunk on the property to a depth of 500 feet and a modern mill and cyanide plant put in.——At the Hayward mine, in Silver City, an electric hoist, mill and cyanide plant will be put in.——The Silver King mine, at Silver City, owned by A. A. Smith, has been bonded for $15,000.——The Dayton mine, in Silver City, is under bond for $30,000, and is being inspected and sampled.

Nye County.

The American S. & R. Co. is preparing to build a 50-ton automatic sampling works in the Lida district. Representatives are now in the field looking over the situation, under direction of San Francisco capitalists. The plant is to be of modern construction, with machinery for grinding and sampling fifty tons daily. The ore will be shipped to the Selby works and other plants of the trust.

Storey County.

L. M. Hall, consulting engineer in charge of the Comstock mines, says he has received orders to at once install the machinery and equipment that is to drain the 3100-foot levels. Two 800 H. P. motors will be placed at the bottom of the Ward shaft in the south end of the lode, and these will lift the waters from the lowest levels to the Sutro tunnel. In this tunnel the old flume will be replaced by a 30-inch pipe carrying 10,000 gallons of water a minute. Power to operate the great motors will be secured at Marmol, on the Truckee river, where a generating station is being built.

OREGON.

By the findings of the mining jury of awards of the Lewis and Clark Exposition, which have just been made public, Colorado receives 161 awards. Nine are gold medals, 13 silver medals and 14 bronze medals, while the remaining 125 are honorable mentions. Oregon stands second in the number of awards with 82. Out of 43 awards received, California got 13 gold, 14 silver and 13 bronze medals, with 3 honorable mentions. Montana got 13 gold, 11 silver and 8 bronze medals, with 25 honorable mentions—57 awards in all. Washington received 70 altogether, but few are gold and silver medals. Among her 55 awards Wyoming got 3 gold medals, 10 silver and 20 bronze, with 22 honorable mentions. Idaho got 29 awards, of which 2 were gold medals, 6 silver, 12 bronze and 9 honorable mentions. Utah received 9, 3 of which were gold, 3 silver and 3 bronze. Many of the States will appeal to the superior jury of awards.

Baker County.

The Cable Cove Power Co. has been organized to build an electric power plant to supply the mines near Cable Cove, including the Valley Queen and Sheridan in Grant county, near Granite. Water is to be obtained from Baldy lake.

The North Pole mine, near Bourne, is running steadily, as is the Columbia. The Bonanza, since being leased by Albert Geiser, the original owner, has been steadily worked, and, from reports, the results are satisfactory. Work is also being done on the Golconda, near Bourne, which has been reorganized. The Virtue, near Baker City, after being shut down for a time, has been sold to a Belgian company and is now reported to be taken out ore and shipping to the Sumpter smelter.

Grant County.

The dredger at Crane Flat, operated by Burch & Burbidge of Spokane, has been shut down for the season. ——It is reported that no work is being done at the Red Boy mine, near Granite.

Josephine County.

Manager F. Fowler of the Gold Pick, near Holland, has completed packing the small stamp mill into that property. Reduction work is to be commenced soon.

The Alder Gulch M. & T. Co., of which A. Osburn is president and W. T. Perry secretary and treasurer, is working in the Oscar Creek district, near Murphy.

SOUTH DAKOTA.

Pennington County.

(Special Correspondence).—Near Rochford the Ethel Co. is sinking a shaft and machinery for this property is being received. At Meyersville the Cochran mine is idle pending the overhauling of the mill and power plant. James Cochran has ore enough blocked out to keep his mill employed for several years. The ore is hornblende schist and is free milling. —— At the Golden West, 6 miles west of Rochford, the mine and mill are running steadily under direction of E. J. Kennedy. It has been found advisable to reduce the tonnage of the Chile mill, as a higher saving of values can be made if less ore be crushed. Canvas tables are being considered as an accessory in saving values from the plates.

Rochford, Sept. 27.

The Egyptian claims, at Keystone, have been sold to the Western Exploration Co. of Salt Lake City. P. O'Keefe is to be superintendent. The plan is to sink a shaft 500 feet before drifting and to put up a 100 stamp-mill.

Lawrence County.

(Special Correspondence).—At Lead the Homestake Co. is building a steel building on concrete piers for another compressor to supply compressed air to motors underground. The building is on the same grade as the Ellison hoist and east of the shaft. At Gayville construction on a separating plant to remove a large portion of the water from slimes is under way. The clear water will be reused and the slimes sent by pipe line to the new slimes plant to be built on McGovern hill at Deadwood. This plant will not be in operation before next spring, as its construction involves a large amount of grading, tank building and other work. At Pluma the tall stack of reinforced concrete at the new electric distributing plant is going up. This plant will supply electric light and power to mines, mills and other industrial concerns throughout the northern Black Hills. At the head of Strawberry gulch, 3 miles east of Lead, the Puritan Co. is putting in cyanide tanks and making other improvements to treat the silver bearing quartzite which constitutes the ore body in this property. The shaft on the Puritan is about 100 feet deep and the ore body 20 feet thick.

Lead, Sept. 28.

UTAH.

Beaver County.

The Majestic Copper M. Co., at Milford, has resumed shipments to the Newhouse mill. The developments on the Harrington-Hickory ground, according to Manager Hanchette, have been encouraging. The Gomer shaft for the last 80 feet has been in first-class ore.

The Moscow mine at Milford is shipping ore regularly. ——A new whim has been put on the Wasatch King in Beaver Lake district. Manager J. C. Brownfield has increased the working force of Milford. The tunnel is in 400 feet.

Salt Lake County.

The Pioneer mine, at Alta, is being developed under the direction of Arthur Murphy.——It is reported that the Centennial-Emma mine, at Alta, has been bonded to a Chicago company.

With a single shot the management of the United States Co.'s lime quarries at Topliff broke up recently 20.000 tons of rock, using 2500 pounds of black powder. There was broken enough limerock to supply furnaces at Bingham Junction for sixty days, as they use an average of 300 tons daily.

The cost of operating the mines, the mill and the tramway at the Alta properties of the Continental Co. has been reduced 50% by Manager Crowther. He has reduced the payroll to 65 persons from 120 and accomplishing the same results.

Summit County.

At the annual meeting of the shareholders of the West Quincy M. Co. of Park City, G. D. B. Turner was elected president and general manager; J. H. Moyle, vice-president; R. E. Miller, secretary, and S. Fargo, treasurer. The report of Manager Turner showed that from the Little Bell, a neighboring property, it had driven 3000 feet to a station 1100 feet under Bonanza Flat. The contact is now being run on, with the main ore bodies expected at its intersection with the fissure cut on the 600-foot level in the original workings.

Tooele County.

T. Jennings, of Salt Lake, has mining claims in the mountains 10 miles west of Grantsville, and has let a contract to Samuel Garnes of Park City to extend the 800-foot tunnel on the Third Term mine. The mines in the Lake Side mining district are being worked, and general activity prevails around Grantsville.

The management of the Honerine mine at Stockton has decided to continue the long tunnel to the main incline, giving a total length of 9500 feet. They will have 800 feet farther to drive. It means the unwatering of other ledges.

The bottom of the incline shaft on the Cyclone Co.'s property at Stockton is in the fissure and a body of good lead ore is being cut. The shaft is down, according to Superintendent H. T. Sappington, 660 feet.

Utah County.

C. B. Snyder, representative of the Snow-Darst Co. at Provo, will give a contract to drive a 300-foot tunnel on the company's holdings east of Provo. The tunnel will be driven near Provo canyon and is intended to open up one of the deposits of broken anthracite coal from which the company intends to generate gas to be supplied to Salt Lake and other towns of the State.

WASHINGTON.

Ferry County.

The Mountain M. Co. put in a 30 H. P. boiler, engine, hoist and machine drills at the Pomeroy mine, 10 miles northeast of Orient.——The First Thought mine, near Orient, in Kettle river district, is shipping 30 tons of ore daily to the smelter.——The shaft on the Comstock-Treadwell mine is gaining depth. This is the property recently bonded by P. Burns & Co.——Preparations are being made to resume work on the Trojan mine on Toulou mountain, near Orient. A new tunnel will be started, which will tap the ore body at considerable depth.

Snohomish County.

A power drill has been put in at the Imperial mine, near Silverton. Air connection has been made with the Copper Independent.——It is reported that work is to be resumed at the Copper Independent.——At the Justice mine, at Monte Cristo, the connection has been completed between the crosscut and the old workings. The production is to be increased.——F. W. Peabody is driving a 600-foot crosscut at the Sidney mine, at Monte Cristo.

Stevens County.

A. I. Goodell, manager of the Northport smelter, announces that the plant would be closed about Nov. 1.

WYOMING.

Crook County.

Paul Danckwardt, superintendent of the Golden Reward M. Co., which owns coal lands in the Sundance coal fields, announces that his company will begin the construction of a power plant at the coal mines and that in addition to operating and developing the collieries power would be transmitted by an electric line to the Black Hills to operate the mining and milling business at that place.

FOREIGN.

AUSTRALIA.

In New South Wales, South Australia and Tasmania marble of excellent quality is found. The principal quarries are at Caloola, near Newbridge. The Hawkesbury sandstone formation, which underlies Sydney, provides a supply of stone adapted to building purposes. Limestone is obtained in New South Wales, where it is largely used in the manufacture of hydraulic cement, as well as for fluxing purposes in smelting works. At Portland, near Wallarawang, extensive works for manufacturing cement have been erected, and works are also in operation at Granville, near Sydney. In South Australia 40,138 tons of limestone were raised from deposits at Yorke's Peninsula. In Western Australia a limited quantity of limestone is raised for fluxing purposes. The establishment of the cyanide process for the recovery of gold in which lime is freely used has led to the opening up of limestone mines in various parts of Queensland. Gypsum of good quality is found in Victoria, the production of 1903 being valued at £897, its use in the production of cement and plaster of paris being yet in its infancy. It is also found crystallized in clay beds in New South Wales, and in isolated crystals in the salt lakes of South Australia, where a small proportion of sulphate of lime is present in the water. In the latter State it is used as a fertilizer. Gypsum is also found in the form of an insoluble salt in Victoria and New South Wales. Quartz is of common occurrence in all parts of the commonwealth. Rock crystal, white, tinted and smoky quartz are frequently met with, as well as varieties of crystallized quartz, such as amethyst, jasper and agate. Asbestos is obtained in New South Wales in the Gundagai, Bathurst and Broken Hill districts. In Tasmania, asbestos is known to exist in considerable quantities in the vicinity of Beaconsfield. Tripoli has been found in Victoria. Mica has been discovered in the New England and Barrier districts of New South Wales. In Western Australia good mica has been met with at Bindoon and also on the Blackwood river, near Cape Leeuwin. Deposits have also been found near Herberton, in Northern Queensland. In the northern territory of South Australia mica has been obtained on a small scale. Kaolin, fire-clays and brick-clays are common in all the States.

CANADA.

BRITISH COLUMBIA.

Boundary District.

Returns from the shipments of ore from the Crescent and Don Pedro, adjoining mines in Skylark camp, gave

over $60 per ton. Work on both properties is being done under H. H. Shallenberger, the manager.——At the Granby mine, in addition to the regular work of stoping and shipping 2000 tons of ore daily, development is going on at the Monarch, Gold Drop and Monte groups, recently bought. The winze in the Old Ironsides mine is down to the 500 level, the deepest workings yet reached in the Granby properties. Work will be started on the new 3-compartment main incline shaft at the Granby.

Work has been discontinued on the E. P. U. mine, near Greenwood, to make repairs to the machinery.

Slocan District.

Work has been stopped on the Mountain Con. mine for the season. The mine is in a basin at the head of the South Fork of Carpenter creek at an altitude of 8000 feet, 8 miles from Sandon, from which it is reached by a wagon road to Cody and a trail to the mine. It costs $20 per ton to carry supplies from Sandon to the mine and $12 a ton to pack ore from the mine to the K. & S. railway at Cody. The ore body occurs in a quartz fissure vein cutting through an abrupt granite peak, and the ore runs as high as $200 per ton in silver and lead. The crosscut tunnel on the Vera has reached the ledge after running 82 feet.

The new crosscut tunnel being driven by the Rambler Cariboo Mines, Ltd., is in 3000 feet, leaving 1400 feet yet to be driven to reach the vein at a depth of 1400 feet. The tunnel is 7½x7½ feet in the clear, and starts from Dardanelles creek, between McGuigan station and the mine. W. E. Zwicky of Kaslo is manager. The cost of hoisting and pumping has stopped work in the 800-foot shaft on the vein until a raise can be made from the tunnel.

ONTARIO.

(Special Correspondence).—The Dreyden district, 200 miles east of Winnipeg, is well mineralized, but little developed. There are several companies working, including the Reindeer M. Co., which recently started its 10-stamp mill. They are preparing to build a cyanide plant in connection with the stamp mill. North from here lies the new district of Sturgeon Lake and it is reported that $150,000 silver ore was taken from the surface by one man in six weeks. In the same district another 10-stamp mill is said to be netting $30,000 per month.

Dreyden, Sept. 29.

YUKON TERRITORY.

(Special Correspondence).—The electric gold dredger at the mouth of Bear creek on Klondike river went into commission August 15. The dredger was built and started digging in forty-six days from time construction work began. It is owned by the Canadian Klondike M. Co., Ltd., and was built by the Marion Steam Shovel Co. of Marion, Ohio.

Dawson, Sept. 25.

MEXICO.

Jalisco.

The Etzatlan smelter, at Etzatlan, has been started as a custom smelter by the Etzatlan C. S. Co., in which B. Kearns, M. E. Raines and E. Finley are interested. The smelter has a twenty-ton water jacket furnace.

The Carrizo copper mine, in the Autlan district, is to be developed by the Carrizo Copper Co., of which K. E. Keller is president. E. E. Nicholson, formerly foreman at the Granby mine in British Columbia, will take charge of the property as superintendent. H. A. Wheeler of St. Louis is consulting engineer.

Sonora.

At a meeting of the Promontorio Con. M. Co., in Nogales, Ariz., R. M. Eberle of Los Angeles, Cal., was elected president; Robert Christie of Owen Sound, Canada, vice-president; A. H. Merwin of Los Angeles, secretary; N. Robinson of Owen Sound, treasurer. Work at the mine has been resumed. Contracts have been let for moving out to the camp the machinery for a 100-ton plant, which has been some time at Nogales. The air compressor will be started at once and work of sinking the deep double-compartment shaft will be resumed.

PHILIPPINE ISLANDS.

H. D. McCaskey, Chief Mining Bureau, Philippine Islands, in a recent report of the United States Geological Survey, states that the outlook for a profitable mineral industry is more hopeful to-day than it has been at any time since the American occupation of the Philippine Islands. Modern machinery has begun to arrive from the United States. Mining development is being carried on in the provinces of Lepanto-Bontoc, Benguet, Pangasinan, Nueva Ecija, Bulacan, Rizal, Batangas, Tayabas, Camarines, Albay, Masbate, Cebu, and Mindanao, and prospecting is being done in almost every island and province of the archipelago. In Suyoc, south of Mancayan, Lepanto, on the Island of Luzon, prospects are being developed by American miners. Gold and copper ores both occur. In Benguet some important development work has been done, particularly in the district of Antamok. Here lie the claims of Kelley, Clark, Petersen, Clyde, Lehlbach, and others, most of whom have been at work on them for several years. Although the ore bodies have not yet been subjected to detailed investigation, this work will be taken up by A. J. Eveland, geologist mining bureau. The ore bodies are apparently extensive. Much of the ore so far uncovered is free-milling. Lehlbach has announced the intention of his company to order a 10-stamp mill with 1000-pound stamps, short drop, and rapid discharge, and a 100-ton cyanide plant complete. Kelley, Clark, Petersen, and Clyde have done sufficient work upon their claims to prove these deposits worthy of serious consideration and the quantity of ore to be large. Kelley has put in a 10-stamp mill with a cyanide plant and Clark has received a 3-stamp triple-discharge Hendy mill and a 60-ton cyanide plant, in charge of C. M. Eye, mining engineer. Petersen and Clyde have built in Manila shops a 3-stamp mill for development purposes. In the Bataan district the Philippine Gold M., P. & D. Co. has opened a number of drifts, but has not yet succeeded in getting its 10-stamp mill upon the ground owing to transportation difficulties en route. In the Bued River district Hanson and Meade have uncovered a rich gold-copper lead, for which a 3-stamp mill is being built. The Tacoma smelter has secured a rate from the Boston Steamship Co., per long ton, free on board, Manila Bay, and delivered on smelter wharf at Tacoma, of $5 per ton. In Pangasinan, in the foothills of the northern Zambales range, near Salasa, a number of claims have been recorded and worked. The ores here are copper carbonate and sulphides, assays of three samples from the claims of W. H. Miller, giving, respectively, 19.9%, 11%, and 18% in copper, 13.2 ounces, 0 ounces, and 2 ounces in silver, and $2.76, $1.60, and $3.80 in gold. In Nueva Ecija, near Gapan, and Penaranda, on the Rio Chico and elsewhere, extensive deposits of placer gold have been known for many years. In the Camarines Province the Spanish concessions upon the extensive gold deposits in the districts of Paracale and Mambulao have been relocated by American mining men under the present laws and without friction with the former concessionaries. In Masbate, in the northern part of the island of Visayas, near the town of Aroroy, work has been done upon claims, principally of free-milling gold ores in quartz, and upon gold placer claims on the Lanan and Guinabalan rivers. Manganese and iron ores of high grade have also been found here, but little attention has been given them. Upon claims of the Eastern M. Co., A. Heise has built a 5-stamp mill to handle the free-milling ores, and upon the trial run of this mill the clean-up from the plates showed $11 to the ton of ore. Upon the placer ground of the Philippine M. Co. on the Lanan River a Risdon dredge has been completed and launched. F. H. Kimball is in charge. Upon the placer claims of the Masbate and Oriental M. Co., on the Guinabatan River, a similar Risdon dredger is in charge of H. J. Robinson.

Books Received.

"The Philippine Mineral Industry in 1905," by H. D. McKaskey, extract from "Mineral Resources of the United States."

As an extract from "Mineral Resources of the United States," the United States Geological Survey has issued the "Stone Industry in 1904." It is largely statistical and deals with the production of granite, sandstone, slate, marble and limestone.

The United States Geological Survey has issued Bulletin No. 256, "Mineral Resources of the Elders Ridge Quadrangle, Pennsylvania," by R. W. Stone; Bulletin 266, "Paleontology of the Malone Jurassic Formation of Texas," by F. W. Cragin, with stratigraphic notes by T. W. Stanton; and Bulletin 271, "Bibliography and Index of North American Geology, Paleontology, Petrology and Mineralogy for 1904," by F. B. Weeks.

As Water Supply and Irrigation Paper No. 143, the United States Geological Survey has issued "Experiments on Steel-Concrete Pipes," by J. H. Quinton. The experiments have been made on large steel-concrete pipes designed to replace the iron, steel or wood stave pipes used in hydraulic work. The author introduces the subject with a discussion of the advantages and disadvantages of iron, steel and wood stave pipes, shows the need for a stronger material, and suggests the use of concrete-steel. He details method of construction and tests, giving results of same. It is concluded that the finished pipe is more durable and costs about the same as the wood stave. The main difficulty is to make a pipe that will stand 100 feet of head of water without leakage through the porous concrete. Many results of the experiments are negative and suggest the necessity for further investigation. The pipes made and tested were 5 feet in diameter inside and 20 feet long, with a 6-inch thickness of concrete shell inclosing an armor of steel rods sufficient to resist a head of 150 feet of water with a factor of safety of 4.

Analytical chemists will welcome a revised edition of "Engineering Chemistry," by T. B. Stillman, a book that is considered invaluable by many engaged in the analysis of iron and fuel. The most notable point in the revision is the improvement, coincident with recent progress, in the analysis of materials of construction. Additional matter relating to asphalts, lubricating oils, Portland cement and the technology of blast furnace products has been incorporated in the book. The methods described are exhaustive, and at the same time are clear and concise. All phases of the analysis, both physical and chemical, of the ordinary fuels and their waste products are treated in great detail. The determination of all elements employed in the manufacture of iron and steel is specifically described. Then follow directions for analysis of various materials of construction. Other materials, whose analyses are described, include paper, alloys, soap, petroleum, lubricating oils, paints, and water for boiler supply. The work seems accurate and reliable throughout. It is published by the Chemical Publishing Co., Easton, Pa., and will be sent postpaid by the MINING AND SCIENTIFIC PRESS for $4.50.

Trade Treatises.

"Dry Air for Blast Furnaces" is the title of an interesting leaflet from the De La Vergne Machine Co. of New York City.

De La Vergne Machine Co., foot of East 138th street, New York City, sends a finely printed and illustrated booklet showing a few of the numerous uses to which the "Hornsby-Akroyd" oil engines are adapted. It contains information valuable to any one interested in economical power production by oil engines.

Personal.

H. C. HOOVER is at Melbourne, Australia.

R. J. FRECHEVILLE is in Rhodesia, South Africa.

A. W. GEIST of Guadalajara, Mex., is now in New York.

FRED C. CORNING is expected in New York from London.

H. A. KELLER has returned to New York from South America.

I. H. ROLKER has returned to London from Western Australia.

PHILIP L. FOSTER is on his way from Lima, Peru, to New York.

R. S. ROBINSON has charge Century mill at Park Valley, Utah.

BEN S. REVETT has returned from Europe and is now in New York.

JAS. GUERIN is superintendent Hunter G. M. Co., near Mullan, Idaho.

W. G. PERKINS is superintendent Nevada Consolidated smelter at Ely, Nev.

JACOB KING has charge New England & Clifton Copper Co. at Clifton, Ariz.

HOWARD W. DUBOIS has returned to Philadelphia, Pa., from the Klondike.

E. C. VOORHIES has returned to Sutter Creek, Cal., from San Francisco, Cal.

R. C. TURNER, superintendent Dolores mine, near Minaca, Mex., is in New York.

JOHN MAYHEW has been made superintendent Big Jack M. Co., at Plattsville, Wis.

C. M. FUELLER has returned to Denver, Colo., from a business trip to Ontario, Canada.

W. J. BRACKING of Wallace, Idaho, is manager North Franklin M. Co. at Mullan, Idaho.

CHAS. D. WALCOTT, director United States Geological Survey, is visiting western Utah.

H. R. PLATE, mining engineer, has opened an office at 501 Majestic Building, Denver, Colo.

JAS. D. HAGUE, president North Star Mines Co., Grass Valley, Cal., is visiting his mines.

W. G. ARKILLS, manager Star tunnel of Clear Creek, Colo., has been in New York on business.

FREDERICK GRUNDY has returned to Los Angeles, Cal., from a mine examination near Ehrenberg, Ariz.

J. M. BOURKE of San Francisco, Cal., is examining mines in the Union Pass section, near Kingman, Ariz.

W. E. GARVER has been appointed manager Mount Theresa M. Co.'s new mines near Idaho Springs, Colo.

W. A. DOUGLAS, general manager Pearl G. M. Co. at Roosevelt, Idaho, has been visiting at Atlantic City, N. J.

J. H. CURLE AND W. A. PRITCHARD are making a reconnoissance of the Oroville, Cal., gold dredging field.

J. W. BUCHER, formerly with the Greene Con. M. Co. at Cananea, Mex., is at 1729 Champa street, Denver, Colo.

OTTY WAKELING succeeds H. S. Shelton as manager machinery department Baker & Hamilton, San Francisco, Cal.

R. R. LESLIE, assistant manager Creston-Colorado Co.'s mines at Torres, Sonora, Mex., is on a trip to Rossland, B. C.

ROBT. C. STICHT, general manager Mt. Lyell M. Co., has been elected president Australian Institute of Mining Engineers.

H. F. BAIN of the United States Geological Survey has been appointed State Geologist for the new Illinois Geological Survey.

FRANK AUGUSTUS has been appointed manager Mountain Monarch M. & M. Co. at Rollinsville, Colo., vice J. C. Barrows, resigned.

C. B. WISNER, president Montana Zinc Co. of New York City, has been in Denver, Colo., on his way to the works at Walkerville, Mont.

G. E. FITZGERALD has succeeded W. S. Dillon as general manager American-Mexico M. & Dev. Co. at San Lorenzo, Chihuahua, Mexico.

H. L. HUSTON, late superintendent Old Soulsby mine at Soulsbyville, Cal., is at Dayton, Nev., examining properties for the Ohio-Tonopah M. Co.

G. D. DOVETON, who has been examining Cripple Creek, Colo., low grade ores for a method of profitable treatment, has returned to Denver, Colo.

J. C. WELCH has been appointed superintendent Alaska Copper Co., which is building a smelter at Coppermount, Prince of Wales Island, Alaska.

H. S. MORRIS, formerly chemist of the Sand Pile cyanide plant in Amador county, Cal., has gone as chemist to the Creston-Colorado mine, Torres, Mexico.

L. T. POCKMAN, for some time past connected with mining in southern Oregon, has been appointed superintendent White Chief M. & M. Co.'s properties, Chinipas, Chihuahua, Mex.

B. S. WILLIAMS has been appointed superintendent Eagle & Blue Bell mine at Eureka, Utah, and James Clark, who has been acting in that capacity since the resignation of James Creighton, has been appointed mine foreman.

Latest Market Reports.

SAN FRANCISCO, October 6, 1905.

METALS

SILVER. — Per oz., Troy: London, 28⅞d (standard ounce. 925 fine); New York, bar silver, 61⅛c, refined (1000 fine); San Francisco, 61⅜c; Mexican dollars, 48c, San Francisco; 47c, New York.

COPPER.—New York: Standard, $16.75; Lake, $16.37½@16.75; Electrolytic, $16.62½; Casting, $16.12½@16.37½. San Francisco: $16.50. Mill copper plates, $17.50; bars, 18@24c. London: £71 5s spot per ton.

LEAD.—New York, $4.90; St. Louis, $4.90; San Francisco, $5.00, carload lots; 5¼c 1000 to 4000 lbs.; pipe 7¼c, sheet 8, bar 6¾c. London: £14 10s ℔ long ton.

SPELTER.—New York, $6.10: St. Louis, $5.75; London, £27 12s 6d ℔ ton; San Francisco, ton lots, 7c; 100-lb lots, 7¾c.

TIN.—New York, pig, $32.37½@32.62½; San Francisco, ton lots, 34c; 500 lbs., 35c; 200 lbs., 36c; less, 37½c; bar tin, ℔ lb., 40c. London, £148 7s 6d.

PLATINUM.—San Francisco, crude, $18.50 ℔ oz.; New York, ingot, $20.50 ℔ Troy oz. Platinum ware, 75@$1.00 ℔ gram.

QUICKSILVER.—New York, $40.00@$40.50, large lots; London, £7 5s 0d; San Francisco, local, $38.00@39.00 ℔ flask of 75 lbs.

BABBITT METAL.—San Francisco, No. 1, 10½c; No. 2, 8c; No. 3, 7½c; extra, 17½c; genuine, 32½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 22.00c; San Francisco, Plumbers', 100-lb. lots, 19.15c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb, .04c.

NICKEL.—New York, 55@60c ℔ lb.; ton lots, 40@47c.

ALUMINUM.—No. 1, 99%, small lots, 37c ℔ lb.; 100 lbs.. 35c; 1000 lbs. 34c; ton lots and over, 33c, Pittsburg. No, 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $15.25; gray forge, $14.75; San Francisco, bar, 3½c ℔ lb., 3¼c in small quantities.

STEEL.—Bessemer billets, Pittsburg, $21.00@$24.00; open hearth billets, $23.00@$25.00; San Francisco, bar, 7c to 13c ℔ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 7¾c; less than 500 lbs., per lb., 8c; in 25-lb. tin pails, ¼c ℔ lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 7½c; do. in kegs, 8c.

LIME.—Santa Cruz, $1.35 country, $1.25 city ℔ bbl.

CEMENT.—Imported, $3.00@4.00 ℔ bbl.; California, carload lots, $1.80 f. o. b. at works; small lots, $2.10 ℔ bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

LUMBER.—(Retail): Pine, ordinary sizes, $24.00@25.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50@5.00; pickets, $21.00;shingles, $2.50 for No. 1, and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00@35.00.

NAILS.—This week the basic prices are: Wire, $2.77; Cut, $3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d, Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4d and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 13½c; Hallett's, 14½c; San Francisco, 1000-lb. lots, 14c; 300@500-lbs. 12c; 100-lb. lots, 13c.

BISMUTH.—Subnitrate, ℔ lb., $2.10.

BONE ASH.—Extra No. 1, 5@6c ℔ lb; No. 1, 4@5c.

BORAX.—Concentrated, 7@8c ℔ lb; powdered, 9@10c; fused, 25@30c; crystal, 7c.

CANDLES.—Spear Brand, 16 oz. adamantine, 40s., 11c ℔ set; 14 oz. adamantine, 40s., 10c; 12 oz. adamantine, 40s, 9c; 10 oz. adamantine, 40s, 8c; 16 oz. stearic, 40s, 12¾c ℔ set; 14 oz. stearic, 40s, 11½; 12 oz. stearic, 40s, 10½c; 10 oz. stearic, 40s, 9½c. 100-case lots and over, ½c less. Not less than 50-case lots, ¼c less. Boxes of 20s, price ½c advance.

CAPS.—3x, $5.50@6 per 1000; 4x, $6.50@7; 5x, $8@8.50; Lion, $9@9.50, in lots not less than 1000.

CHEMICALS.—Cyanide of potassium, 98%–99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c ℔ lb.; caustic soda, in drums, 3@3½c ℔ lb.; Cal. s. soda, bbls., $1.10@1.20 ℔ 100 lbs.; sks., 90c@$1.00; chlorate of potash, 12@13c; nitrate of potash, 6½@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2½@2¾c; flour sulphur, French, 2¾@—c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 5½@5¾c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66% B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

CHROMIUM.—90% and over, ℔ lb., 80c.

COAL.—San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lot, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $8.50, long ton; Colorado Anthracite, $14.00. Coke, $11.50 per ton in bulk, $13.00 in sacks; Sunnyside, $8.50, long ton.

FIRE BRICK.—Domestic, carloads ℔ 1000, f. o. b., factory square, $25.00; soap and split, $22.50; arch and wedge, $27.50; skewback, $30.00; circle, $32.00.

FIRE CLAY.—Domestic, ℔ ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, $8.50.

FUSE.—Triple tape, $4.00 per 1000 feet; double tape, $3.55; single tape, $3.10; Hemp, $2.85; Cement No. 2, $3.10; Cement No. 1, $2.75, in lots of 3000 and up.

OILS.—Linseed, boiled, bbl., 54c; cs., 59c; raw, bbl., 52c; cs., 57c; Lucol oil, boiled, bbl., 51c; cs., 56c; raw-bbl., 49c; cs., 54c. Kerosene—Pearl, per gal., 17½c; Astral, 17½c; Star, 17½c; Extra Star, 20½c; Eocene, 19½c; Elaine, 26c; Water White, in bulk, 11c; Mineral Seal, iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 14½c, do., cs., 21c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 12½c; do., in cs., 19c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 57½c; cs., 62½c; Sperm, crude, 63@68c; Natural White, 68c; Bleached, do., 57c; Whale Oil, cs., 52@67c.

LITHARGE.—Pure, in 25-lb. bags, 9½@10½c ℔ lb.

MAGNESIUM.—Pure, N. Y., $1.60.

MANGANESE.—Black oxide, ℔ lb., 2¾@4c.

MERCURY.—Bichloride, ℔ lb., 77c.

MOLYBDENUM.—Best, $2.75 ℔ lb.

PHOSPHORUS.—American, ℔ lb., 70c.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1**, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2**, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

RED LEAD.—500 lbs. and over at one purchase, ℔ lb. 7½c; less than 500 lbs., 7¾c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 54c

SODIUM.—Metal, ℔ lb., $1.

TUNGSTEN.—Best, ℔ lb., $1.20.

URANIUM.—Oxide, ℔ lb., $3.40.

Commercial Paragraphs.

THE S. H. Supply Co., Denver, Colo., are furnishing tanks for a 150-ton leaching plant to the U. S. Reduction Co., Colorado City, Colo., and a 100-ton leaching plant with crushing department, consisting of two No. 2 Wild mills and Sampson crushers to New Mexico.

C. M. FUELLER, 1750 California street, Denver, Colo., reports having recently secured an order for 10-stamp mill for Birmingham, Alabama. Work is to commence in the next thirty days.

CHAS. M. SCHWAB says that the Union Iron Works of San Francisco, Cal., is to have additions to its present capacity to the extent of increasing its facilities for the manufacture of mining machinery to equal that of any similar establishment in the United States.

THE Blaisdell Co. of Los Angeles, Cal., have a contract, through Chas. C. Moore & Co., engineers of San Francisco, Cal., for an installation of the Blaisdell system in the new cyanide plant of the Tonopah M. Co., Nevada. The Blaisdell Co. have the sole agency in the United States and Mexico for the Robins Conveying Belt Co. of New York on all work relating to cyanide plants.

THE American Car & Foundry Co. has added to its equipment at the Madison plant, Granite City, for the construction of steel and composite cars, among the equipment being 100 Boyer long stroke riveting hammers manufactured by the Chicago Pneumatic Tool Co. The company reports business in general continuing good and the prospects bright for the remaining months of the year.

THE Ingersoll-Rand Co. of 11 Broadway, New York, announces the establishment of a branch office at Houghton, Mich., under the management of T. F. Lynch, who has for several years past represented the Ingersoll-Sergeant Drill Co. in the copper and iron districts of the north. At the new office a complete stock of repair and duplicate parts for all Ingersoll-Rand machinery will be carried, assuring ready service to patrons of the company in the territory covered.

THE Power and Mining Machinery Co. of Cudahy, Wis., report the following contracts recently secured for mining machinery: Shannon C. Co., Clifton, Ariz., complete converter plant, including four 7x10-foot hydraulic converters of new design. This plant, when complete, will be modern throughout; Colusa-Parrot M. & S. Co., Butte, Mont., six 7x10-foot electrically driven converters; American S. & R. Co., new Garfield plant, near Salt Lake City, Utah, twelve 8x10-foot hydraulic converters of the same type as the Shannon and Colusa-Parrot; the same company, Aguas Calientes, Mexico, plant, three 8x17-foot vertical copper converters; Old Hundred mine, near Silverton, Colo., complete 40-stamp mill, electrically driven.

Obituary.

W. V. O'DALY, a mining man well known in Arizona and Mexico, was assassinated at Choix, Sinaloa, Mexico, on Sept. 28.

HENRY SEINCKE, aged 70 years, died at Boulder, Colo., on the 30th ult. He was the last of the four men who invented the diamond drill.

GENERAL DIRECTOR RICHARD AKERMAN of Stockholm, Sweden, reports the following statistics of the production of iron ore, pig iron, etc., in Sweden, in 1904, in metric tons: Iron ore, 4,408,647 tons; pig iron, 528,525 tons; charcoal blooms, 189,246 tons; bar iron and steel, 181,175 tons; nails, wire rods and iron and steel, 102,976 tons. During the year there was an average of 331 furnaces in blast, with an average daily production per furnace of 15.1 tons.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING SEPTEMBER 19, 1905.

799,866.—CAR COUPLING—Bennetts & Jones, Tacoma, Wash.
800,068.—WHIP SNAPPER—Bronaugh & Kistler, Los Angeles, Cal.
800,067.—BUILDING BLOCK—H. D. Brooke, San Francisco.
799,851.—SASH LOCK—H. Conboy, San Francisco.
799,891.—UNITING STAVES—D. Crane, San Francisco.
800,084.—WATER HEATER—W. C. Dice, Seattle, Wash.
800,111.—PARTITIONS—W. C. James, Los Angeles, Cal.
799,905.—TRAVELING ATTACHMENT FOR BUILDINGS—T. McConnell San Francisco.
800,000.—MODEL—C. Melrose, San Francisco.
799,920.—CHECK REIN—L. Moretti, Santa Cruz, Cal.
800,008.—RAIL JOINT—I. A. Oliver, Santa Clara, Cal.
799,801.—SEWING MACHINE TABLE—Pangburn & Olea, Seattle, Wash.
799,937.—SWAGE—J. A. Reid, San Francisco.
799,758.—ELEVATOR LOCK—R. J. Roulo, San Francisco.
799,870.—STONE SAW—W. B. Ruble, San Francisco.
799,806.—NURSING BOTTLE—E. H. Simonds, Berkeley, Cal.
799,684.—ELECTRIC FUSE—Snyder & Hardison, Santa Paula, Cal.
800,025.—TOY—A. Stein, San Mateo, Cal.
799,949.—OIL BURNER—H. B Stilz, Seattle, Wash.
800,029.—INSECT CATCHER—M. Terletzky, Goble, Or.
800,032.—SOAP TRAY—F. H Turner, Suttley, Cal.
799,765.—THRUST PLATE—A. W. Tweeden, Tacoma, Wash.
799,811.—OBTUNDER—C Van Wyck, San Francisco.
799,820.—CAN—Young & Symonds, San Francisco.
799,821.—CAN—Young & Symonds, San Francisco.
799,822.—CUFF HOLDER—M. P. Zindorf, Seattle, Wash.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

DIAPHRAGM PUMPS.—No. 800,356. Sept. 26, 1905. Frank Briggs and George N. Briggs, Yountville, Cal. This invention relates to improvements in pumping apparatus, and particularly in that class of pumps known as diaphragm pumps as distinguished from the ordinary plunger pumps. Its object is to provide a simple, practical pump devoid of bushings through which leak may occur and convertible at will from a lift to a force pump, or vice versa. It comprises a unitary structure, a divided casing and a centrally apertured flexible diaphragm secured between the two parts of the casing, said diaphragm aperture reinforced, a non-rotatable guide fixed centrally in the aperture of the diaphragm, a sleeve of less length than the guide and slidably mounted thereon, said sleeve having at one end an adjusting nut engaging a threaded portion of the guide whereby the sleeve is movable vertically on said guide, and having a foot piece or stop at the opposite end, and a flexible disk valve loose upon the guide and having a central opening through which the guide passes whereby the guide directs the loose valve in its opening and closing movements from and toward the aperture in the diaphragm.

VEHICLE TIRES.—No. 800,357. Sept. 26, 1905. Floyd Burnham, Fresno, Cal. This invention relates to a tire which is especially adapted for buggies and all carriages. The object of this invention is to provide a tire having all the advantages of a tubular elastic casing with a substantially rigid interior support, which is provided by an ordinarily formed rope of sufficient diameter to entirely fill the interior of the casing. It comprises an improved tire composed of an outer tubular casing having relatively thin walls of substantially uniform thickness and forming an inner chamber which is concentric with the exterior of the tube, and a multistrand rope filling said inner chamber and supporting the walls of the casing.

AMALGAMATOR.—No. 800,378. Sept. 26, 1905. Henry L. Lightner, San Francisco, Cal. This invention relates to an apparatus for the amalgamation or saving of precious or valuable metals. Its object is to combine with a surface of mercury or an amalgamated surface a device adapted to discharge air under pressure upon said surface in such a manner as to move the material which has been delivered upon the surface and to separate therefrom any gold or valuable heavy substance, which separated material will be retained and the gangue will be discharged. The device may be employed in various ways, either operating in a direct line or as a revoluble apparatus. The apparatus comprises a circular amalgamated concave surface, means for supplying water with pulp containing valuable metal centrally upon the surface, an air blast apparatus, a conducting pipe and radially disposed arms having perforations adapted to discharge a blast of air downwardly and outwardly upon the inclined surface.

CONCENTRATOR.—No. 800,379. Sept. 26, 1905. Henry L. Lightner, San Francisco, Cal. This invention relates to an apparatus for the concentration of substances having varying specific gravity. The apparatus comprises a tub with vertical slots made around its periphery, vertically movable gates having openings made therethrough, means for supplying pulp to the tub, an air blast apparatus, a revoluble vertically adjustable tube connected with said apparatus, and having radially perforated arms projecting from the lower end, and means by which said tube and arms may be gradually raised in unison with the movement of the gates.

BALING PRESSES.—No. 800,384. Sept. 26, 1905. Chas. L. Miller, Berkeley, Cal. This invention relates to improvements in baling presses, and especially that class which is designed for baling hay and like substances. It is especially designed to be used in that class of presses having a vertical press box with a means for delivering charges of material into the upper part of the box, these charges being successively compressed by means of a follower which is moved downward by suitable connections, so as to compress the charges successively into the lower part of the press box, and when the bale has been completed and tied it is removed through a door opening, which is located below the point at which the material is delivered into the press. The device comprises a press box with an inclined cutaway side contiguous to the discharge door, a plate loosely fitting said cutaway section, and stops fixed to and swinging with the door, by which the plate is automatically moved forward or released by the closing or opening of the door.

SPLASH PLATES FOR STAMP MILLS.—No. 800,398. Sept. 26, 1905. Geo. C. Richards, Oakland, Cal. This invention relates to improvements in stamp mills, and especially in splash plates used in conjunction with stamp mill mortars. The invention resides in the use of vertically disposed amalgam plates instead of ordinary straight non-amalgam surface splash boards, the object being to save as much gold as possible where a good chance is offered to save it, and to prevent scouring, as would occur if a straight amalgam surface was used. It is not customary, however, to use amalgam plates in this connection, because the sand and water would scour off all the amalgam or "silvering," and leave nothing for the values to adhere to; employ a mortar having a conical ore chamber and segmental screens, disposing the latter coaxial with the chamber, so that all the splash from a stamp acts at right angles to the screen surface. The invention comprises the combination with a stamp mortar having a screened opening of a corrugated plate exterior to said opening and having an amalgamated surface presented toward said opening.

POWER PUMP HEADS.—No. 800,399. Sept. 26, 1905. Geo. C. Richards, Oakland, Cal. The object of this invention is to provide a power pump head which will be very simple in construction, easily set up and easily knocked down for shipment, which is adapted for either single or double acting pumps for deep wells, and which will be powerful and absolutely rigid. It comprises a triangular end castings having integral axially alined journal boxes at their apices, side castings disposed between and bracing the end castings, and long tie bolts passing through the end castings and side castings and extending across the latter.

Dividends.

Bunker Hill & Sullivan M. & C. Co., dividend No. 97, $150,000, payable Oct. 4th, a total paid since January 1, 1905, of $2,775,000, and total to date, $5,046,000.

Common Sense

teaches us that **RUBBER** against an article creates friction. In fact, we wear rubber soles—use rubber on steps, etc., to prevent slipping—to create friction.

Why do you use **ENGINE PACKING** with rubber on top—on the bottom—and in between—where it is rubbing against the rod all the time—creating excessive friction—loss in power—fuel—money?

No such mistake in

"EUREKA" PACKING.

The rubber is where it should be—embedded in flax—which takes the wear—the lubricants prevent friction.

Isn't it up to you to try **GENUINE "EUREKA,"** particularly as the price is one-half less?

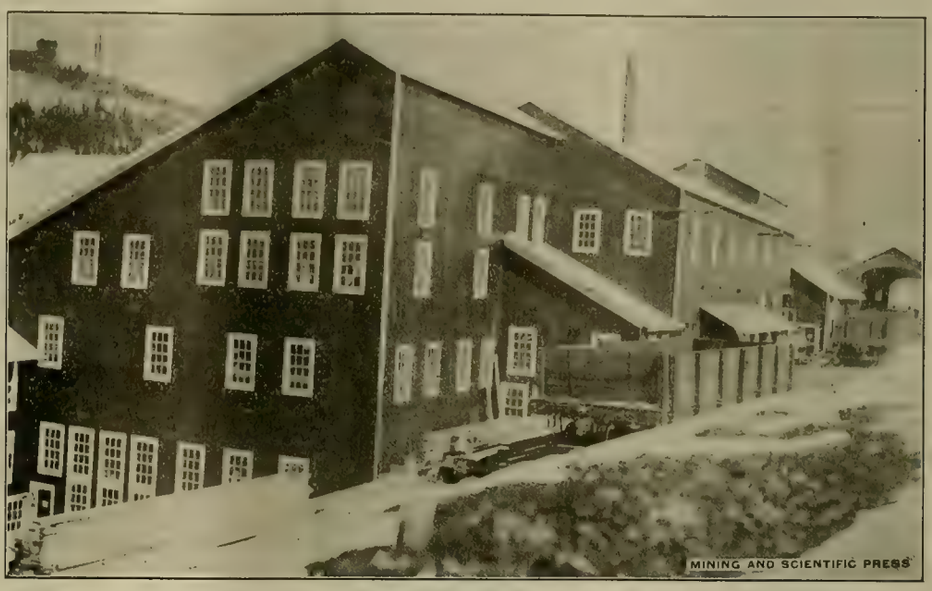
The Prospector and His Claim.

Good mines do not always fall into good hands. In this instance, by good mines are meant those which possess the elements of success, and by good hands is implied the ownership by those who are able to properly equip, develop and operate these mines. There are mines which require little capital at the outset, producing high-grade shipping ore from the grass roots, but such mines, though in former years fairly abundant in certain districts, are no longer so easily found. A man whose capital is limited to his strength and skill as a miner is placed at a disadvantage, as compared with the one who has the necessary capital of his own, or the backing of friends, in his enterprise. He may own a really meritorious property, as its development may later prove, but is unable to equip or develop it except in a very small way. He may perform a small amount of labor on it for a period of years, and in time dispose of the claim for a nominal sum, when the purchaser at once supplies the needed means, equips the property, and in a few months has it on a paying basis. Most miners who have good prospects realize fully the possibilities of their holdings, but, while realizing their own inability to develop and equip the mine, still ask a price so high as to prevent anyone from investing in what must necessarily be, at first, somewhat of a hazardous venture. The usual result is that the poor owner continues to be the owner, without making material headway. In such cases it is usually the part of wisdom to sell a good prospect for a reasonable price, and to use a part of the money thus secured in the development of another claim—as the prospector generally has a number of promising locations. In this way he may rise from absolute helplessness to a condition of independence and thereafter be able to proceed with the further development of his property in the same manner as the capitalist, and possibly with equally good results.

The prospector is, as a rule, not an experienced business man, nor is he always an accomplished miner and metallurgist, and for this reason he sometimes fails to accomplish the results secured by others later on the same property. Ordinarily it is the desire of the prospector to sell his claim at the highest price obtainable, and to continue to prospect as before, being unwilling to give up this most alluring of pursuits. These are the reasons why the owners of prospects wish to sell their holdings—unable to work them themselves, and not caring to be anything else than a prospector. "Once a prospector, always a prospector," is a common saying, and, generally speaking, is true. The prospector, after a fortunate sale of property, proceeds to enjoy himself after his own fashion, and in time, when funds run low, he goes optimistically forth once more into the wilderness, in the firm belief that he can repeat the exploit—a conceit which does not always materialize, but he continues to prospect just the same. There are many exceptions to this latter, the typical prospector, but he usually follows the well-beaten trail of his kind. The mere fact that the prospector offers to sell can in no wise be considered as evidence that his claim is worthless, for, as a rule, an experienced and successful prospector will spend little time on a poor showing. If he has done much work on the property, it may be taken as a sort of prima facie evidence that he has something worth looking into.

On one occasion the writer made a trip of 30 or more miles in Arizona to inspect a prospect on which the owner represented he had done over a thousand dollars' worth of work. On arriving at the mine the development was found to consist of one small hole which could have been dug in two days. The vein was small and not particularly promising. In explanation, this fellow said he feared, had he told the truth, he would not have succeeded in inducing any one to take a look at the so-called mine. It is needless to say that he was not from the ranks of the typical prospectors, but was a fraud who did most of his prospecting about town with his pockets bulging with other people's ore.

The investor can usually afford to listen to the bona fide prospector, and, making the necessary allowances for over-zealousness in description on the part of the latter, may safely offer to at least investigate what he has to proffer in the way of an undeveloped mine.



The Rowe Concentration Mill at the Portal of the Yak Tunnel, Leadville, Colo. (See Page 259.)

Prospector's Summer Camp in the High Sierra. (See Page 261.)

THE Transvaal government has appropriated $10,000 toward defraying the expense of a commission to investigate the means of preventing accidents incident to hoisting in shafts. It is said that the character of some of the shafts on the mines of the Rand is such that the deterioration of ropes is rapid and consequently dangerous. It has been found that in the upcast shafts, particularly, the corrosive effect of the polluted mine air on the hoisting ropes was very noticeable, the action mostly taking place in the interior portions of the cable, and where it could not be readily observed. The practice has been to handle most of the men through these upcast shafts, but it has become a matter of such importance that a searching inquiry into the existing conditions and means to lessen the danger is now deemed necessary. The mining rules of the Transvaal do not require that a mine have two shafts, though the advantage which two or more shafts possess is well known, but for commercial reasons it has been found expedient to overlook this matter, and good ventilation has been secured in most instances through the connection of the workings of adjoining mines. It may be that the commission referred to will suggest that the mining laws be so amended as to make two shafts a legal necessity. Safety-hooks to prevent over-winding are in general use on the Rand, but up to the present many shafts have no safety clutches attached to the skips or cages, though their necessity is recognized throughout the mining world elsewhere.

The Value of Observation.

Many of the most successful mine managers owe their success to the habit of observation. They are quick to see whatever comes within the range of their vision; prompt to appreciate any advantage in a new device or method successfully applied, and are able to adapt the ideas and principles which this observation suggests to their own business elsewhere. There are others who, with the same or superior opportunity, fail to either see, understand or appreciate the object lessons which the successful operations of others should teach. Not infrequently men of this stamp are managing mines for other people.

There are in the United States many great and successful mining enterprises, and some of these are managed in a manner so practical and so thoroughly sensible that all may learn something by observing the methods employed, and carefully studying the various processes in the numerous departments which lead to ultimate success. The greatest gold mine in the world at present is undoubtedly the Homestake combination at Lead, South Dakota. The writer recently had an opportunity to visit and inspect the surface equipment and underground workings of this great property, after an absence of nineteen years. Having been familiar with the mine in its earlier history, its tremendous development and stupendous equipment were the more noticeable by comparison with what it had formerly been. There seems little lacking about the great plant, and the few improvements and additions to meet present requirements are being provided as rapidly as possible. There are six great shafts and hoisting plants; six mills containing in the aggregate 1000 stamps; two cyanide plants—the largest in the world—for the treatment of sands, and an equally large plant for treating slimes is to be built. There are machine shops, foundries, storerooms and warehouses, railroads, canals, ditches, pumping plants, and every accessory requisite to the greatest success. Millions of dollars have been invested in surface plant and millions more underground, but the mine has paid for it all, with the exception of an assessment of $200,000 levied in 1877–78. A rich mine can supply and afford all that may be necessary in the way of equipment, but the Homestake is not a rich mine; it is simply a series of vast low-grade ore deposits—so low grade that no extravagance is permissible. Notwithstanding all the above elaborate equipment, and the expenditure of the millions of dollars, which have been necessary to make this great mine a success, not a single innovation, not a new venture in plant, process or method, has been adopted without careful consideration and trial. From one end of this vast property to the other, from the surface to the lowest level, nothing is done by guess, no expensive installations are made before their necessity has become evident and their adaptability proven.

Throughout—underground and on the surface—one is impressed with the mature thoughtfulness evident in every operation, and in the application of every mechanical device. It is true, changing conditions have resulted in changes of plant and method from time to time, but when an installation is made it is the best that experience can suggest at the time, even though later it may be deemed advisable to displace it by another machine or method. Time and again the methods of mining have been changed, until to-day the methods in vogue are probably the best that can be applied in each particular case—for the ore is not all mined by the same method. Some stopes are much larger than others, and in some places the rock is softer than in others. The method adopted for each particular mine or stope is that one which has been found to give the best economic results at each place, irrespective of the others. Although mining has been reduced to almost an exact science on the Homestake belt, the engineers in charge are still studying the conditions and endeavoring to accomplish still better results, and without doubt they will succeed.

In the early history of these mines all underground stopes were heavily timbered, but not filled. The great stopes caved, and a different method had to be sought. Stopes were then timbered and filled with waste rock. This prevented caves, but was so expensive that some means of reducing the expense was sought. By degrees a method was evolved which has resulted in a great reduction in the cost of mining. The great stopes are now extracted with a minimum of timber, all of the ore is recovered, and the breaking of the ore is cheaper than before, as the miners are not limited in the amount of ore they may break, as they often were when the expensive square sets were in place. A plan is now being devised to reduce the cost of mining the pillars left after stoping out two rooms. The plan will result, if successful, in largely doing away with the shoveling of that block of ore. In a pillar 42 feet wide, 100 feet high and 500 feet long (the width of the vein) this will effect a saving of about $25,000. As the original stopes are 60 feet wide and the alternating pillars will be 42 feet, this will mean the saving of a large sum of money on each level.

The instance here mentioned is but one of the many improvements constantly being made. At the present one is inclined to believe that perfection has been about reached; but the experience of the past shows that this is improbable, and that the future will witness other changes in equipment and methods which will still further reduce the cost of mining and milling on the Homestake. It is safe to assume, however, that no radical change will be made which has not been first carefully studied out in its every detail and tested fully before it is adopted.

For many years the tailings from these mills ran to waste from the plates, the only effort to save any values being a few strips of brussels carpet, over which the pulp passed on its way to the canyon. The plate area was increased and silvered copper plates were put in. These were among the first in the United States. A section of plate was added below the original apron plates, but this lower plate was given a greater width than the old plate next to the mortar. This second plate saved considerable additional gold. A third and wider plate was added and a still further saving resulted. There being no room for more plates in the mills, plate houses were built, and in these one may see the unusual spectacle of thousands of square feet of silver-plated copper plates, over which the pulp runs in a thinly distributed sheet. When these great plate areas are being dressed the men walk about on them, sweeping them backward and forward with full-sized house brooms. Each of these plates yields a quantity of amalgam every twenty-four hours, which suggests that possibly additional plate surface may not be amiss. The providing of these extra plate areas was an abrupt departure from mill practice elsewhere, but the wisdom of the installation has been long since demonstrated. T. J. Grier, the manager of this great property, has grown up with it and he is familiar with its every detail. Many of the innovations are the outcome of his own careful study and observation; other ideas have been supplied by the efficient corps of engineers, foremen and assistants.

As stated above, the addition of what would elsewhere be probably considered abnormally large plate area resulted in the saving of much additional gold. Still the tailings carried an increasingly larger percentage of values as the mine workings went deeper and the proportion of oxidized ore grew steadily less. The cyanide process was then tried on these ores and was found to be fairly satisfactory at the outstart. C. W. Merrill took up the proposition. It was a large one—the largest in the world, as far as quantity of material was concerned. The method of treatment was worked out along rational lines. Improvements were made from time to time. Special apparatus was devised to meet various requirements and the methods were adapted to existing conditions. A system of classification was worked out and resulted in an almost perfect separation of sands and slimes. The sands were found to be readily amenable to cyanide treatment by percolation. The slimes, however, to the extent of 1600 to 1800 tons of material, still contained values upwards of $1 per ton, and these were and at present are still being used to sluice the sands from the tanks. By means of a long series of experiments involving many disappointments and failures, Mr. Merrill has eventually worked out a method by means of which these slimes may be treated at a profit.

Although such satisfactory results have been obtained in mines, mills and cyanide plants, the managers of the various departments are still endeavoring to make further improvements, that expense may be lessened and returns increased. It is only through a knowledge of the details of this great undertaking that one may fully appreciate what is now being done, and to what extent the methods of the present are superior to those of the earlier days on the Homestake.

There are few mines which could not find something in the equipment and methods of the Homestake worth following. Necessity has had much to do with the results now being obtained. It is only recently that it was decided that the water pumped from Spearfish creek over a divide to the head of Whitewood creek, several miles south of Lead, could be made available as a source of power. For some years this water has flowed down the bed of Whitewood gulch, to be taken up lower down and carried by flume to Lead. The water is now to be conveyed in pipes and a pressure of several hundred feet secured, when the water will be utilized to generate electricity, which will supply power to various motors at the mine, while the water will still be available for mill use as before.

Notwithstanding the fact that the Homestake mine stands as an eminent example of careful, conservative and successful management, whether viewed from the practical, engineering, scientific, metallurgical or business standpoint, there are within the radius of 5 miles of Lead some of the most ill-advised installations that may be found anywhere. There are mines equipped in a manner that one would not expect from any one but a novice who had never had an opportunity to see anything better—mills built in cramped position, with numerous devices to handle material that should be handled by gravity—for good mill sites are available close at hand. In one mill the grizzly was found so clogged with broken ore that not a pound of the fines could pass through to the bins beneath. In another the ore from the breaker

was so large that it would barely pass the feed slot in the mortar. This was inexcusable, for the reason that the breaker could crush to inch cubes if desired. Other similar defective methods and installations are in evidence, and always where better results could have been obtained, as the conditions were favorable to the application of the best appliances and methods.

The managers and superintendents of these mines evidently do not realize how impractical their installations are. They do not know, and in some instances, at least, they will probably never become aware that they do not know. With the unusual opportunities for observation of thoroughly practical up-to-date installations, mining methods and metallurgical practice, there seems little excuse for these so-called mistakes.

Notwithstanding the excellent examples supplied by the Homestake and some others, millwrights and others continue to place rock breakers in the mills and above the level of the floor, necessitating the shoveling into the crusher of every pound of ore. The apron plates are allowed to bank up with sand until one-half or more of the area is covered and therefore useless as an amalgamating surface. The feed in some instances is so fast that the mortars fill up and holes are constantly punched through the screens. Canvas tables are allowed to run for days without cleaning up, and are therefore serving no useful purpose. The mining methods are in some instances extraordinary—the work being done for to-day only, with no thought of the morrow. The result is the mines are being gouged, leaving the ground in bad and dangerous condition. Soon work must come to a standstill, as no more ore will be available without sinking, or filling the old stopes, in order that the backs, in which there remains thousands of tons of ore, may be reached. In some of these mines great headers are run through the ore, the work being carried up from 20 to 50 feet or more, the miners standing on the broken ore. The ore is then shoveled into cars and sent out of the mine, leaving the back high overhead and out of reach for the future, unless timber or filling be put in. This has not been the outcome of necessity, but is the result of a short-sighted policy.

Many other instances of flagrant mismanagement might be mentioned, but those cited are sufficient. The same conditions obtain in other districts and in other States, but they are particularly noticeable in Lawrence county, S. D., because of a comparison with the Homestake, which one can not avoid making, and because there seems no excuse for the lack of observation on the part of the managers of some of the mines of that district, for which every opportunity is afforded.

Live Business Methods.

A good example of business nerve is afforded in Cleveland, Ohio, where nearly all the machinery of a plant has been sent to the scrap heap, to be replaced by new machinery. It had been in use only one year, was in fine condition, cost over $200,000 to install, but the owner ruthlessly "scrapped" it for good business reasons—new and improved devices for the same kind of work had just come out and he felt that as between replacing his $200,000 outfit or running behind in the competitive race, it was economy to put in the new machinery, even though it involved throwing out the machines of which he had been so justly proud only a year previous, and which had cost what was in itself a fortune. It was simply a case of good business judgment, the quick, decisive action that puts the American manufacturer to the front and keeps him there.

This week comes another example of the same kind, which, while it does not involve the immediate pecuniary loss accompanying the case cited, is unique in its relation to the business itself. C. A. Schieren has one of the biggest belt making establishments in the country—and has thrown out all the belts in his own plant. The Schieren belt plant power is now furnished by direct-connected electric motors, and in their new big factory belts for other people to use for distributing power are made by machinery driven by direct-connected motors, instead of by belts, as before. This system has cost them a good deal extra, but, like the Cleveland establishment, they figure that it is economical. As for the fact being detrimental to the prestige of their business, they show that in other lines of business belts are still necessary and will be used, and that it does not follow that because they discard shafting and belt connection that others need do the same thing, it being with them a simple case of economical action. Mr. Schieren says "the simple turning of our shafting used to daily consume 15 H. P. There is a saving of $2000 per year in that one item."

Whether it be the factory, the mine, the mill or the smelter, the present effort is to adopt the most economical device to do the desired work, regardless of what it costs or what is discarded. Nor is the idea solely for the immediate time, to be determined by the expense or profit of the first year. In an established business that looks considerably ahead, it is always reckoned good business to seize upon possibilities of decreased cost of production whenever presented.

At What Depth Do Gold Mines Quit?

There is a growing tendency on the part of experienced mining engineers to discover some relation, or connection, between the enriched portions of veins and ore deposits and the topography of the country. In many instances the richest portions of veins are found at and near the surface, and particularly on the elevated ground through which a vein passes, while those portions lying in the canyons or along the lower ground do not, as a rule, afford equally satisfactory results. There are exceptions, and these are numerous, but without doubt the greater number are of the character above indicated.

For many years mining engineers and geologists have tried to establish the theory that there is no apparent relation between the occurrence of payable mineral and the topography of the country, but the more extensive the development of mining regions, the more noticeable the fact becomes, that there is apparently such relation.

In some districts it is much more noticeable than in others, but in a general way such relation can be traced out. The causes for this condition are, as yet, speculative, but are presumed to be due to secondary enrichment, caused by the downward flow of surface waters. Nearly all veins carry more or less iron sulphide, which, decomposing, partly becomes altered to iron sulphate. A solution of iron sulphate is said to have the power to dissolve gold in much the same manner as solutions of potassium cyanide. If this be true in nature (as it is known to be in the laboratory) then the iron sulphate solutions slowly dissolve to very fine gold, and reprecipitate it at convenient places in its downward flow—at the intersection of the vein with floors, cracks, seams, and with other veins. The pocket hunter is familiar with these accumulations of gold, at what he knows as "crossings." A floor or fault in a vein usually results in enriching that portion of the vein immediately above the floor or fault plane, and often there is little or nothing below it. Instances of this character are particularly numerous. Another locus of enrichment is in those portions of the vein where there is a flattening in the dip, forming a sort of roll or floor, on which there is often an accumulation of richer ore, and sometimes a pocket.

A careful study of the occurrence of gold in pocket mines would probably throw much light on the subject of ore deposition and particularly on the secondary enrichment of gold-bearing veins and deposits. The richest pockets ever obtained from California mines were found near the surface, or at least in the oxidized zone. The noted mass of gold found on Carson hill, in Calaveras county, at the Morgan mine, in 1850, occurred at the surface, the entire amount coming from the surface pit not over 30 feet deep. Other large pockets were found near the surface. The largest pocket found in the Bonanza mine at Sonora, in Tuolumne county, was obtained within 100 feet of the surface—vertical measurement. Other noted pockets in other mines have been found at or near the surface, while comparatively few—and no very large ones—have been discovered at great depth.

A noted writer stated recently in a current publication that it was doubtful if any gold mine was as rich below 1000 feet from the surface as it had been above it. There are many instances to prove that this statement is not borne out by the facts, for in California there are numerous mines which have proved to be richer below 1000 feet than above that depth. Among the mines illustrating the fallacy of this supposition are the Kennedy mine and Argonaut, near Jackson, the Central Eureka and Eureka mines, near Sutter Creek, and some of the mines of the Grass Valley region.

Then there are mines which continue to be largely profitable below 1000 feet which have also been good above it, but it cannot be said that this richness, nor that of the mines previously mentioned as being better below the 1000-foot level than above it, are due to secondary enrichment. In these cases the condition seems to be normal. To what depth the payable ore (or ore of the same grade as that now being mined) will continue, it is, of course, impossible to predict. As mining operations go deeper, the cost per ton usually increases somewhat, while the grade of ore may not improve, if it even remains as good as it is at present levels. Secondary enrichment, however, is a different proposition, and there are those who even say that no payable ore will be encountered below the zone of downward circulation of surface waters; but those who profess this belief fail to point out clearly where this level is to be found.

Payable ore is still found in the deepest gold mines of the world—those of Colorado, California, and Victoria, Australia. The latter are down 4000 feet, with pay ore still in sight. The deepest California mine is down about 2800 feet, with good ore in the lowest level. Some Colorado shafts have penetrated below the 2000 level, and the mines still are prosperous. At what level may we expect them to become barren? Deep mines may become unprofitable because of increased expense, while the value of the ore remains the same as above. On the Rand, in the Transvaal, for instance, the gold-bearing banket continues to produce nearly the same average values as above, while the expense of mining increases as the levels are carried to deeper and still deeper levels, this being due entirely to economic and not geological conditions.

A careful review of all that is known of the genesis of ore deposits, and particularly of secondary enrichment, leads to the inevitable conclusion that there still remains much to learn about both original and secondary ore deposits. At one time secondary enrichment was not recognized as an important factor in mining, but a study of the remarkable phenomena of the ore deposits of Butte, Montana, forced the conclusion upon the observing engineers that the rich ore bodies of some of the great mines of that district were due wholly to secondary enrichment. No one now doubts that the phenomenally rich ore of Fryer Hill, at Leadville, Colo., Treasure Hill, White Pine, a score of places in Arizona and Nevada and elsewhere, were due to similar causes. The gold mines of California owe their surface richness to the same cause. The notably rich deposits at Goldfield, Nevada, must be ascribed to this secondary enrichment, as must almost every other occurrence of unusually rich ore at or near the surface.

It may be that rich accumulations of gold ore in depth, such as those occurring in Cripple Creek district, in California and in many other places, are due to somewhat similar causes. The water levels may at one time have been much higher or lower than now, for in all mining regions is found usually abundant evidence of oscillations of the region up and down—now rising, now falling. These changes take place slowly and extend over a long period of time, but the best that may be said is that the problems of ore deposition and alteration have only been partially solved.

THE question in Mexico of what a "dollar" means has been authoritatively settled. The Department of Finance of Mexico has decided that the word "dollar" shall mean the American gold dollar, and that when the Mexican silver dollar is meant the word "peso" shall be employed. Some time ago an American resident at Tampico wrote "dollars" on a check, and the Tampico bank cashier to whom the check was presented paid the amount in gold values. The drawer of the check claimed that it was his intention to have silver paid. Litigation was threatened, but upon investigation the authorities decided against the drawer of the check. The Mexican ruling applies to all documents—notes, drafts, etc.

CONCENTRATES.

WHERE patent has been applied for to a mining claim the pending of patent proceedings does not excuse the performance of the annual labor prior to the issuance of a certificate of purchase by the Government to the claim owner.

ALUM used in paper manufacture is quoted in New York about as follows: For lump mineral $1.75 per 100 pounds; for ground alum $1.85 per 100 pounds; for porous $1.00 and for the powdered variety $3.00 per 100 pounds.

PULVERIZED mica is used in the manufacture of lubricants, and also in making certain kinds of wall paper. Sheet mica is bought by large stove manufacturers, and the smaller sheets are used as insulators by electrical manufacturing companies.

AN oxygen base consists of a positive (basic) radical joined by oxygen to hydrogen. An oxygen acid consists of a negative (acid) radical joined by oxygen to hydrogen. An oxygen salt consists of a positive radical or radicals joined by oxygen to a negative radical or radicals.

THAT steel rusts much more readily than iron under ordinary atmospheric conditions, is well known. This is supposed to be due to the fact that the microscopic particles of carbon and other substances in the steel render it more easy of attack by oxygen in the presence of moisture.

THE performance of an amount of work or improvements in excess of $100 during any year on an unpatented mining claim does not permit the claim holder to carry this excess over and charge it to the following year. If $1000 worth of work be done, or improvements made this year, not more than $100 of it applies for this year, and none of it can be credited to next year.

THE "market for burros" in any particular locality is a matter upon which no exact information can be given. On general principles, it may be assumed that in a district where much prospecting is in progress there would be a demand for these useful animals, particularly on the desert, where they can subsist on less than almost any other beast of burden. Southern Nevada should afford at present a good field for the burro stockman.

MINERAL claims cannot be "taken up" on agricultural lands which have been patented. If mineral is discovered on patented agricultural land after patent issues the only way to get possession is through purchase or lease. It is not necessary to file a mining location on such land. Mineral veins on patented agricultural lands have no extralateral right—that is, the owners have no right to follow the vein on its dip beyond the boundaries of the property. Otherwise mines may be worked on agricultural lands the same as elsewhere.

THE Helena, Mont., copper ore would bring $6 per ton and would cost $7 per ton to smelt and mine. The plan seems to be to haul an ore of about $16 per ton and hauling cost of at least $10, to be mixed with the copper ore in hope that some money could be made out of it. It is difficult to see how this could be worked to be a profitable venture and it is not strange that the smelter is shut down. Answering the last question—that it would be quite possible to estimate the possibilities of smelting this ore without the expense of an experimental run. The cost of such an investigation would probably reach $1000, but from data furnished it is doubtful if it would pay.

ABOUT 20 years ago a record run was made at a large hydraulic mine in California, where the cost of washing gravel did not exeed 3 cents per cubic yard. This was accomplished in a somewhat unusual manner. The bank was first prepared by drifting, crosscutting, etc., for a heavy blast. This having been placed and fired, the water was carried on to the face of the bluff above the pit, and allowed to fall in a cataract upon the broken loose gravel, which it gradually washed away, leaving the gold upon the irregular surfaces of the bedrock, to be cleaned up later by a few men. No manual labor was employed in the washing, and no water was used under pressure. As a result the costs were unusually low.

WHERE "stoping without timbers" is practiced on an extensive scale, it usually will be found necessary to reinforce the sets of the main gangways, as the pressure of the shifting masses of broken rock wrench the timbers first in one direction and then in another, depending on the settling of the mass. The timbers can never be kept in perfect alignment, but usually do not seriously interfere with tramming. Square set timbering costs from 20 to 50 cents per ton of ore extracted, depending on the price of timbers, the size of timbers used, cost of framing and labor in placing. Blockholing and shoveling in stopes where no timbers are used costs not to exceed 20 cents, and is therefore to be preferred to timbering, being cheaper, and all the ore may be recovered. Filling costs more or less, according to existing conditions.

THE slope angle at which the sides of a ditch or cut will remain open without caving depends upon the character of material and its position as regards dip. Some material, like cemented gravel, will stand with vertical sides. Near Auburn, Placer county, Cal., is a railroad cut in this kind of material, which is in places over 80 feet deep (Bloomer cut), which was made in 1867. It has never caved and the slope of the sides ranges from 80° to vertical. Some volcanic material, such as tuff, will stand when cut by vertical excavation. Stratified and slaty rocks give the most trouble, particularly when they have a dip of over 30°. One side of the cut may remain firm while the other constantly caves. Some material which stands well dry will not stand at all when wet, particularly that containing clay or talcose minerals.

GOLD accumulated on the plates of a mill makes the best amalgamating surface, but there is no real need of carrying several hundred ounces on a single plate for this purpose. A mill plate cannot be subjected to a more harmful practice than that of scraping its surface with steel chisels or other implements of metal. It not only removes the film of gold so desirable in amalgamation, but also the silver plating beneath, and it lowers the fineness of the bullion, owing to the presence of silver and copper. The gold should be allowed to accumulate in a thin film over the plate, and nothing harder employed in the cleanup than a solid rubber, such as is provided for this purpose. If the gold is entirely removed, the surplus amount thus taken off must be replaced on the next run (and this is always attended with more or less difficulty), before the plate is again in proper condition.

THE North Bloomfield ditch, according to A. J. Bowie, was 8.65 feet wide on top, 5 feet at the bottom and 3½ feet deep. It was run on a grade of 16 feet to the mile and discharged 3200 miners' inches. From 1870 to 1877 the North Bloomfield Co. washed 11,021,630 cubic yards of gravel, the average amount moved being 4.6 cubic yards per miners' inch. The nozzles used were 6 and 9 inches diameter, the head of water 450 feet. The pipe line was 22 inches diameter in the main line and 15 inches in the branches. At times the face of the bank was carried to the height of 250 feet. The yield of 1,858,000 cubic yards of gravel washed in 1874–75 was 3.99 cents; 2,919,700 cubic yards washed in 1875–76 produced 6.6 cents per cubic yard. During 1876–77 the amount washed reached 2,293,900 cubic yards, which yielded at the rate of 12.68 cents per cubic yard. The cost per cubic yard during the several periods was: 2.86 cents in 1874–5; 3.25 cents in 1875–6 and 6.19 cents in 1876–77. The misstatements found in some works dealing with mining operations and costs are difficult to account for.

SULPHURIC ACID is employed in the manufacture of fertilizers. Calcium phosphate is treated with the sulphuric acid to form what are commonly known as superphosphates of lime. The chemical reaction is as follows: $Ca_3(PO_4)_2 + 2H_2SO_4 = CaH_4(PO_4)_2 + 2CaSO_4$. The calcium sulphate is filtered off and the super-phosphate is left in solution. The commercial super-phosphate manure is a moist mixture of calcium phosphate—$CaH_4(PO_4)_2$ and calcium sulphate ($CaSO_4$). It is prepared for the market by mixing the ground mineral phosphate with sulphuric acid. Its chief value lies in the large amount of soluble phosphate it contains. The compound deteriorates in time. A portion of the soluble phosphate reverts to insoluble phosphate, owing, it is supposed, to the action of the super-phosphate upon some of the undecomposed calcium phosphate remaining in the compound, resulting in the formation of the insoluble hydrocalcium phosphate. The presence of the sulphates of aluminum, magnesium and iron also have a bad effect on the super-phosphates, converting the phosphoric acid into insoluble forms. A super-phosphate is also made by dissolving bone ash in hydrochloric acid, precipitating with ammonia and digesting the washed precipitate of calcium phosphate with phosphoric acid. On evaporation the salt crystallizes.

AS TO the adaptability of the diamond drill in prospecting: It may be used to advantage in any firm ground. In soft or loose ground it usually proves unsatisfactory, and mining by ordinary means is not usually expensive in ground of this kind. When deciding to employ the diamond drill in prospecting two things are of greatest importance—a knowledge of structural and mining geology, and a man to set the diamonds and run the drill who thoroughly understands his business. The drill runner may be an experienced and capable man with his machine, but know nothing of geology. The probable result would be much loss of time and money in working at random. If the services of a competent geologist can first be secured to outline the general plan of operations, when this is understood the drill runner may then be trusted to go ahead under instructions, and results secured should be of value. Drilling must be conducted systematically and a careful map made showing the direction and depth of each hole and formations passed through. In this way a correct record is compiled, from which afterward the proper conclusions may be drawn. A diamond drill in proper hands affords an excellent means of prospecting at a minimum cost, otherwise the entire outlay may be a waste of time, money and energy.

WHEN driving a raise it is always a good idea to divide it by a partition, using one side for the passage of rock or ore, and the other for manway. This may be done by putting a line of stulls in a vertical raise, or posts, as they would be called in an inclined raise, and spiking planks to these timbers. By arranging a chute at the bottom, the rock broken above may be drawn into cars and handled cheaply. If the ore or rock is drawn away as fast as broken above, the partition will afford good ventilation. If the ore pass is allowed to fill up, only enough being drawn away to keep that side of the raise full, the air circulation will be reduced. If the latter case is necessary, a pipe should be carried up the manway side and air forced into the raise, either by means of fans or compressed air. In some mines a jet of compressed air is sent into a pipe of larger diameter extending up into a raise or stope. This jet gives the air in the pipe an upward movement and additional air from the atmosphere surrounding the pipe at its lower end is carried into the pipe by the suction. This is proper and usually satisfactory if the air at the foot of the pipe is free from foul gases, but which it usually is not. In the latter case a circulation of air results, but the air being already vitiated does not afford the necessary relief. When a long raise is started, sinking from some point above to make connection as quickly as possible is always advisable, and when the winze and raise approach each other sufficiently conditions may be improved at the last by drilling a long hole downward in the winze to connect with the top of the raise. A circulation of air may thus be secured when the faces are still 20 feet or more apart. Although the drill hole will be small, it will be found to make an appreciable difference in atmospheric conditions. If the winze above is wet, the water can be conducted to one side of the raise.

THE following notes on assaying copper ores by the cyanide method are from Ricketts & Miller's "Assaying:" The method is based on the decolorizing of an ammoniacal solution of copper nitrate by potassium cyanide. The reactions are complicated, as different organic compounds are formed under varying conditions. For this reason it is essential to the accuracy of the method that the bulk of solution, the temperature, the excess of ammonia, the quantity of ammonium salts, and approximately the amount of copper in the solution shall be the same as in standardizing. The solution for titration is made by dissolving 22 grams of pure potassium cyanide in water and diluted to 1 liter. In standardizing, weigh out portions of pure copper of about 200 milligrams each; dissolve in 10 c.c. 1.2 gravity nitric acid in a beaker capable of holding 200 c.c.; boil out the fumes; dilute with cold water to about 80 c.c.; add caustic soda solution till a slight permanent precipitate forms; then add 6 c.c. strong ammonia, specific gravity, 0.9. Run in cyanide solution from a graduated burette till the blue color is very faint, then dilute the solution to 150 c.c. and continue adding cyanide a few drops at a time until the blue color has disappeared. The bulk of the solution should be 150 c.c. at the end of each case. To obtain this the operation is continued until but a few drops more are required, then diluted to the correct volume. The beakers should be marked at a point where they hold 150 c.c. In making the assay—dissolve the ore, matte or bullion as already described; precipitate the copper by aluminum or zinc, or as sulphide by means of hydrogen sulphide, dissolve the precipitate in nitric acid and proceed as in standardizing. The amount of KCy solution required to discolor the blue solution indicates the percentage of copper present.

TO give a proper outline of treatment of any ore from description only is most difficult, and usually is also unsatisfactory. The Mexican ore containing gold $6, silver about 20 ounces, manganese dioxide 6.45%, etc., leaves a doubt as to the character of the silver—whether native, chloride or some complex compound. Naturally one would first expect to be able to amalgamate at least a portion of the gold on plates or in pans, and possibly, also, some of the silver. The manganese oxide may give some trouble in amalgamation, which can in some measure be overcome by the employment of a quantity of quicklime fed regularly with the ore at the rock breaker. The amount to be used must be determined by trial. The result of attempts at subsequent concentration is wholly speculative. If the silver occurs as black sulphide, and stamps are used in crushing the ore, a very limited saving of the silver sulphides will result. Another type of mill would give better results. Naturally it is desirable, if possible, to avoid roasting the ore owing to increased expense. The "dead roasting," it is said, resulted in good extraction of gold, but low on silver. In roasting ores for chlorination it is very important that the heat should not be too high in the early stages, or insoluble compounds of silver are likely to result, and the same may be the case in cyanidation. It is never possible to say whether or not the cyanide process is adaptable to any particular ore even after analysis. The experiment must be tried on a scale sufficiently large to demonstrate its commercial adaptability. The fact that a better extraction can be obtained from sands than from slimes is probably due to mechanical causes. These two classes of ore can be completely separated by a series of hydraulic classifiers, and each treated separately. Ordinarily there is no difficulty in treating the sands by percolation, but the slimes require an entirely different treatment — filter pressing or in some other manner—the scheme in each case to be worked out.

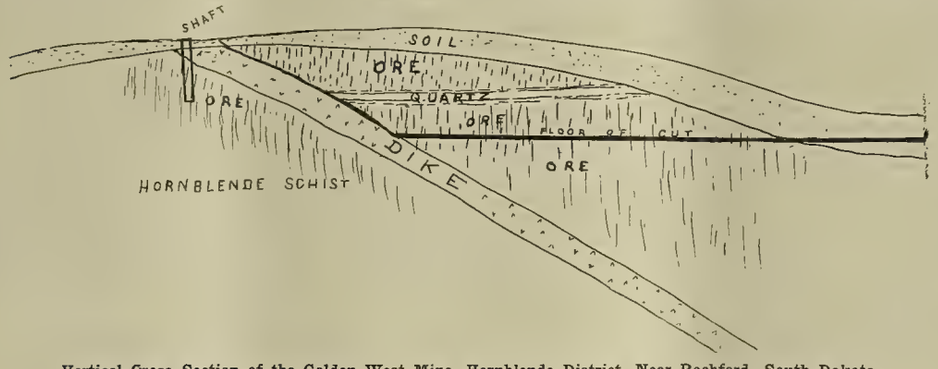
The Golden West Mine, Pennington County, South Dakota.

Written for the MINING AND SCIENTIFIC PRESS by W. H. STORMS.

One of the most interesting and unusual gold-bearing deposits in the Black Hills of South Dakota, a region noted for its strange and remarkable ore deposits and minerals, is that owned by the Golden West Mining Company. Some weeks ago there appeared herein a description of the mining methods in vogue at this property, written by E. J. Kennedy, the superintendent. Since that time the writer has had an opportunity to personally inspect the mine and plant and to watch its operation. A further description is not only of interest, but is justified by the facts. The geology of the deposit is of particular interest, and may be said to be an anomaly among the numerous gold mines of the Black Hills, there being no duplicate or other similar deposit there so far as known to the writer.

The ore deposit occurs near the summit of a group of rolling hills, near the head of what is known as White Weazel gulch, and about one-half mile from Castle creek, in Hornblende district, 6 miles west of Rochford. It cannot be said to occupy a basin, and yet, for most part, the deposit is found at the side of a "saddle" between the hills and is nearly flat. The country rock is hornblende schist, with numerous small stringers, and a few veins of larger size, of white or bluish granular quartz. The entire mass is impregnated with auriferous iron sulphide and free gold. The ore near the surface is colored, red, yellow, brown, black, and various other colors, in many shades, the result of the oxidation of the sulphide minerals. The strike of the formation is a few degrees west of north, and its dip slightly from the perpendicular to the eastward. Naturally in such a formation, and under the conditions described, it would be expected that the ore deposit would conform closely in strike and dip with the rocks in which it occurs. It may be that this will eventually be found to be the case, but as far as the development has progressed it leaves this important matter in some doubt.

The accompanying diagram will aid in giving an



Vertical Cross Section of the Golden West Mine, Hornblende District, Near Rochford, South Dakota.

understanding of the conditions as far as they have been determined by present development. As previously stated, the formation is nearly vertical, and is covered by soil and other debris to depths varying from 1 to 8 feet where exposed in the cut. About 15 feet from the surface on the west side of the cut is seen a flat sheet of quartz cutting the schists at nearly right angles. This quartz is shattered by pressure and slight movement, is mineral stained and gold bearing, as well as the schists both above and below it. The cut is irregular in outline, but is rudely circular and about 100 feet in diameter. On the south side of the cut the ore is abruptly cut off by what appears to be an intrusive massive rock dipping 17° to the eastward. This dike-like mass is seemingly a type of coarse-grained diorite, and consists largely of fibrous hornblende grouped in brush-like bunches with white feldspar, and little or no quartz. The rock presents every physical appearance of being a dike, which it probably is. It is wholly devoid of the schistose structure so pronounced in the overlying schists. A shaft sunk a few feet back from the rim of the open cut was started in this hard, tough diorite, but passed through it and entered schist similar to that above the dike, and this lower zone of schist is known to be gold-bearing also. The relative position of this shaft and lower ore zone is shown in the sketch. This seems to indicate clearly the dike-like nature of the massive amphibole rock. If further development of the mine proves this to be the correct conclusion, the dike is probably of pre-Cambrian age. In the northern Black Hills there has been extensive dynamic action, and dikes, both large and small, are very numerous. The northern Black Hills also furnish a number of examples of typical laccolithic intrusions, but south from Custer's peak few, if any post-Cambrian intrusives are known. The geological age of most of the igneous rocks—porphyries, felsites, rhyolites, andesites, phonolites, trachytes, etc. — is thought to be as late, if not later, than Cretaceous.

In the central and southern Hills, however, there are many intrusions of basic rocks, principally diabase and diorite. In the village of Rochford, near the Montezuma mill, a large diorite intrusion occurs in the micaceous and hornblende schists, and near the head of Irish gulch, 2 miles north of Rochford, a quartz-bearing diabase dike may be seen. Near Lookout, on Castle creek, are several dikes of diorite and diabase, showing that the Algonkian age in the Hills was not free from this sort of disturbance.

The Golden West mine involves some interesting problems in mining and transportation. Up to the present time mining and milling have been accomplished at very low cost, but in the future this cost will probably be somewhat higher. As stated above, the upper ore deposit is covered with from 1 to 8 feet of soil, grass and tree roots, and drift from the neighboring hills. This has largely been mined with the ore heretofore and sent to mill, but as the breasting out of the ore proceeds in the cut the thickness of this overburden increases somewhat, and although it contains some gold it is generally an insufficient amount to make its transportation and milling profitable. A method of stripping and disposing of this waste material must soon be provided. The lower ore zone is almost wholly unknown, but if on exploration it is found to contain payable values over a considerable area, it might be the better method to mine this zone or sheet, whichever it proves to be, and to fill the underground stopes with the waste from the surface. This would afford a means of disposing of what is now a source of expense, while providing a cheap filling for underground workings. It is not known whether the underlying schist is again cut by a second and lower dike, or whether it will form a zone of gold-bearing schist extending, like the Homestake, to indefinite depth. In either case the mine will be able to continue to supply a large amount of ore to the mill, and when contemplated improvements have been made the cost of milling, transportation, and possibly mining, may be somewhat reduced. Should it be found that the lower zone is of great depth when the ore lying above the dike has been removed, the dike itself could be broken and employed in filling the lower workings.

At present all ore is supplied from the superficial workings of the open cut. The ore is picked and barred down, being loose and easily mined, and very little powder is required. The ore is shoveled up at the face into cars and trammed a short distance to the loading bins, from which it is drawn into the buckets on the aerial tramway. At most terminal stations the buckets are pushed around the terminus by the men, but at this plant an automatic device takes the buckets when released from the running rope, at the lower end of the terminal, and by means of lugs on a chain the buckets are carried forward and are dumped automatically into a hopper which feeds the rotary rock breaker. The bucket continues on its way and the clip on the running rope automatically clutches the bucket carrier and the bucket is returned to the upper terminal. This tramway is 2700 feet in length and operates very satisfactorily, but it has a far greater carrying capacity than is demanded of it at present. An increase in tonnage would result in a decrease in running expense of this branch of the business.

Upon passing the rock breaker the ore falls into a large bin and from that by means of a chute goes to an automatic feeder, which discharges into a large Chile mill. Some time since this mill was run at higher speed than now and the feeding was forced so that the capacity reached 100 tons daily. It was found that by reducing the feed somewhat better amalgamation could be done. In the judgment of the writer the screens in use are too coarse, and finer crushing would result in reducing the values in the tailings materially. The plate surface, too, is deemed inadequate, and should at least be double what it now is for the amount of pulp passing over it. The mill is provided with one stationary plate 4 by 12 feet and two shaking plates of similar size.

The mill is so arranged that an additional grinding machine may be set up beside the first. As the company has an abundance of power available, it would be economy to add this equipment. The mine, the tramway, crusher, and entire paraphernalia are able to supply and handle the additional ore and the installation of another mill would materially reduce the cost of operations.

Selling Timber From the Forest Reserves.

The new rules for the national forest reserves, announced by the Secretary of Agriculture on July 1, were made to give freer use of the reserves to the residents of the States in which they are situated. Experience has already shown that they are welcomed.

The West understands what this means better than does the East. From the first the East has believed in the reserves and declared that there could not be too many of them; but in the West the first effect of their proclamation was widespread alarm. It was feared that the reserves would check the development of the region, would burden neighboring communities with taxes, and would prevent the taking for local needs of the timber which lay close at hand. Both in the East and in the West the wrong idea prevailed that a reserved forest was not for use.

A forest reserve is meant to yield up its wealth, as a farm does, or a stream which turns the wheels of many mills. In the long run it should both guard and increase the resources of the country in which it lies.

The mere creation of forest reserves, without provision for their administration, was therefore both ineffectual and annoying to local interests dependent upon their resources. Consequently the Secretary of the Interior, in 1896, requested the National Academy of Sciences to recommend a national forest policy. This resulted in the passage of the act of June 4, 1897, under which, with several subsequent amendments, forest reserves are now administered.

On the theory that the management of land, not of forests, was chiefly involved, this law gave the Secretary of the Interior authority over the reserves, and provided that their surveying, mapping and general classification should be done by the United States Geological Survey, and the execution of administrative work by the General Land Office.

The result was not satisfactory. The technical and complex problems arising from the necessary use of forest and range soon demanded the introduction of scientific methods and a technically trained force, which could not be provided under the existing system. The advice and services of the Bureau of Forestry were found necessary, but, under the law, could be but imperfectly utilized. The necessity of consolidating the various branches of Government forest work became apparent and was urged upon Congress by the President and all the executive officers concerned. Finally, the act of February 1, 1905, transferred to the Secretary of Agriculture entire jurisdiction over the forest reserves except in matters of surveying and passage of title.

Scientific forestry means wise use—not the locking up of forest wealth, but putting it to profit under well known laws which control the right utilization of the forest. It is just because a second crop is desirable that the first crop calls for the forester's ax, and the forester's skill is again needed in the reservation of seed trees and, above all, in protection from fire.

So when the reserves were transferred to the care of the forest service, in the Department of Agriculture, work was at once begun to bring the forests into larger use, to develop their resources both for the needs of settlers and for the good of the forest itself. The office was moved nearer to the applicant; that is, more authority was given to the forest officers on the reserves, so that settlers entitled to the free use of timber, as well as those wishing to purchase timber in small quantities, might be served on the spot, without delay. Whenever timber is wanted on a larger scale, experts are assigned to report on the advisability of a sale, and where large transactions are in due course completed, the timber is removed under contracts which provide for a second crop by fixing a diameter limit, by careful logging methods, and by burning the slash to prevent fires. Twenty-two forest assistants, assigned as technical assistants to forest supervisors, are at present engaged in the making of working plans. Forest inspectors inspect and report upon all the work done on the reserves.

Besides these technically trained foresters there are also employed forest supervisors, rangers, and guards. To these men is given general administration and care of the reserves. They must know their regions, be familiar with local conditions, and combine good sense, independence, and the physical, mental, and moral qualities which make good woodsmen.

The Secretary of Agriculture has, under the law, discretion to allow or refuse free use of forest reserve timber and stone by "bona fide settlers, miners, residents and prospectors." This free use is intended merely to provide for the immediate needs of the individual himself, not to permit him to cut timber for sale to others. Free use is expressly refused to sawmill proprietors, owners of large establishments or commercial enterprises, and companies and

corporations. The free-use privilege is also refused to any trespasser.

Under the present scheme of administration all timber on forest reserves which can be cut safely and for which there is actual need is for sale. Applications to purchase are invited. Green timber may be sold except where its removal makes a second crop doubtful, reduces the timber supply below the point of safety, or injures the streams. All dead timber is for sale.

There are three classes of timber sales. Setting aside California, where every sale of any class of timber must be advertised for sixty days, the classes are briefly these: The first includes dead timber worth not more than $20, on application to a forest ranger or a deputy forest ranger; the second, dead and living timber, worth not more than $100, for which the forest supervisor's approval must be secured; and the third, timber worth more than $100, which must be advertised, and can, as a rule, be approved only by a forester. All timber must be paid for, in full or in installments, before it is cut.

The local officers of the reserves receive all applications for permission to cut, and grant permission for small amounts, but they receive none of the money paid for timber or for any other use of the reserves. No one but the special fiscal agent of the forest service, in Washington, D. C., is authorized to receive any payments whatsoever. The regulations promulgated by the Secretary of Agriculture specify that:

"All money, whether payments, deposits, or settlements, must be sent direct to the special fiscal agent and not transmitted through a forest officer. Money must always be sent by postal money order, express money order, or national-bank draft on New York. Other forms of drafts, cash, checks or certified checks will not be accepted."

A Miner's Measuring Pole.

Written for the MINING AND SCIENTIFIC PRESS by MATT. W. ALDERSON.

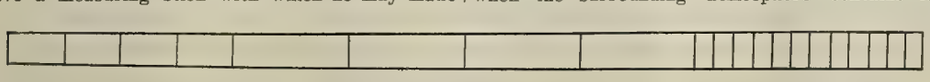
I called on a neighbor a few days ago, my nearest neighbor to the west, 6 miles away. For four years we had received our mail from the same postoffice and yet had not met. I found him a robust man, just past three score, a man with whom it was a pleasure to converse; for it was easy to see he was blessed with sturdy common sense. For eight years he has been prospecting at the head of a gulch for the vein from which rich placer deposits below him were supposed to have been derived. A few hundred feet from where he is at work one nugget was taken out valued at over $3000. If the generally accepted theory is correct he is doing intelligent work. But that little word "if!" And the tragedies that follow the belief in false theories!

But I am not writing of theories just now. The work of the man showed he had put heart into it. His tunnel was straight as an arrow and the timbering such as to delight the eye of a mechanic. Part of the tunnel was through soft ground and the sides were lagged up with stone — granite broken in driving the tunnel — laid dry, with the face as smooth as the wall of a well-built house. I stood back in the tunnel and looked out. It seemed as if there was not a cap in a distance of 150 feet that was a quarter of an inch out of line.

I could but think that a man who did such work was worthy of splendid remuneration. And in most lines he would receive it. But, as a friend says: "All the paths on this globe are not smooth ones. Some of the rough ones naturally occur in the Rocky mountains."

As I passed out of this man's tunnel I noticed his measuring stick and I said to myself, "There's a good idea." It was short, but embodied something I had not thought of. It was good any way it happened to lie. I have used measuring sticks for years in mines, but the marks on them were simple notches on one side. My neighbor's measuring stick had grooves that went entirely around the stick. And its advantages in other respects must be apparent to every man who does measuring of rough work around the mine.

To make these serviceable measures, take round, smooth sticks 1½ to 2 inches in diameter and of such length as will be most useful for the work in hand. For tunnel work let one stick be 4 feet and another 7 feet. On one end of the sticks mark 1 foot in 1-inch lengths, the next foot in 6-inch lengths. On the other end mark the first foot in spaces 3 inches apart, the next foot in 6-inch lengths. The space between the 2 feet on each end may preferably be in markings of 1 foot. Then carefully groove the marks around the sticks, cutting the groove in about one-eighth of an inch. Do this carefully with a saw, and one will have a measuring stick with which he may make accurate measurements even in the dark. Illustration herewith shows how such a stick will look when finished.



A Miner's Measuring Stick.

Extinguishing a Fire in a Pyritous Mine.

On the 27th ult., in an address before the students of the Mining College at the University of California, Berkeley, Cal., Lewis T. Wright, general manager of the Mountain Copper Co., gave an account of an underground fire in the Iron Mountain mine, Shasta county, Cal., and how it was overcome:

"The Iron Mountain mine is a large mass of cupriferous iron pyrite. In mining this the immense cavities formed by the galleries, stopes and workings are filled with rock. In course of time it was found that the mine temperature had increased and was increasing. The ventilation system was that almost invariably used in metalliferous mines, viz., natural ventilation. The pyrite in places became hot, and it became necessary to aid the ventilation by means of fans. One morning a faint odor of sulphurous acid was observed, and by midday it had increased to such an extent that a large part of the mine had to be abandoned. The mine was on fire and the gases from the fire made it impossible to live in the workings. The fire proceeded rapidly through parts of the filling and the workings, burning out the timber. That fire was extinguished by heroic means and the use of water. The problem now was to find a means of cooling the working places so that work could be carried on, to prevent gases from fires that might originate in filled ground from spreading to the workings, to extinguish fires that might originate in covered ground without interfering with the operations, and to prevent small traces of gases from such fire from entering the workings where their presence would drive out the miners.

"What was the cause of the heating of the ground that was the precursor and cause of the fire? Some thought it was the pressure of the backs on the filling. No doubt in the settling and packing of this by immense weight above there might be some heat generated. So many million tons falling so many feet in such a time would produce a calculable amount of heat. Some thought it was the kaolinization of the rock filling and adjacent country. I reasoned as follows: A mass of pyrite dry and at normal temperature like a specimen in a museum does not get hot, does not oxidize, and may from all we know last a million years without change if so preserved. But a heap of pyrite exposed to moisture and oxygen does oxidize or sulphatize. That reaction produces heat. The majority of such chemical actions proceed at a greater rate as the temperature rises.

"I once performed the following experiment on a coal that was known to be fiery: I powdered it into a fine condition, moistened it, and left it in a heap. When it commenced to warm up I placed some of it in a tube and allowed at first air to pass through it but very gently. It became warmer. I then increased the flow of air and it became hot, and then by greatly increasing the flow of air brought it into a state of vivid combustion. The essence of this experiment where there is such chemical action producing evolution of heat is to take care to lose heat by radiation at a lesser rate than that at which it is produced. The temperature then will rise and rising the action proceeds at a faster rate and the gain in temperature becomes increasingly rapid, and finally vivid combustion ensues.

"Heaps of cupriferous pyrite in Spain are washed judiciously with water for the extraction of copper, and their temperature rises, thus promoting the desired sulphatizing action, but the temperature is not allowed to rise to the point of combustion. I have seen heaps of iron filings by careful watering and protection from loss of heat brought in their interior to melting point. A single wisp of straw does not rise in temperature, but a heap of straw will get hot if damp and may catch on fire by itself.

"The heating of the ore was caused by the action of oxygen with moisture or water acting as a carrier. There are other factors in this problem. The workings had to be ventilated, but it will be thought that the adding of air to fire would be dangerous. Take the case of a coke fire burning actively in a grate. By throwing and spreading out the embers on the ground they will cease to burn and cool off. An excess of air will in that way put out the fire. With the natural system of ventilation then in use at Iron mountain I had frequently occasion to observe that air coming from certain crevices would put out the light of a candle. I had other evidence that the ground as a whole was porous.

"There was still another factor in the problem — an extinctive atmosphere — one in which certain classes of combustion cannot proceed for reason of either a total want of the combustion supporting element — oxygen or its dilution by other inert cooling gases Carbonaceous flames will extinguish when the surrounding atmosphere contains less than a certain amount of oxygen — say about 15%. This is an extinctive atmosphere for such flames. The roasting of metallic sulphides proceeds less slowly when the gases surrounding contain deficiency of oxygen, and will cease entirely when the oxygen falls below a certain amount, though still present to an appreciable amount. If the heat production is less than the heat loss by radiation or air cooling then the temperature of a burning body will fall, and, falling below the temperature of ignition, will cease to burn.

"These were all factors in the problem I had before me. There was porous ground, there was a material that was combustible and that could heat itself and take fire, and that could be cooled if hot, and if on fire could be extinguished either by a great excess of air or deficiency of it. I then argued, by forcing through the drifts a sufficient quantity of air I can cool off the external faces of heated blocks of ore. If I can maintain in the interior of the blocks of ore and filling an extinctive atmosphere I can prevent accumulation of this interior heating. By maintaining in the open workings an atmospheric pressure slightly above that in the ground which is practically that of the atmosphere, I can prevent the gases from the interior penetrating into the workings and driving us out of them with their suffocating properties. By not making this pressure too high I can hold the gases, so to speak, in the interior, where they will act as an extinctive atmosphere. I then had powerful fans fitted up at certain entrances, which were closed by doors, and provided with entry for the air from the fans, and ordered that air was to be driven by the fans through the workings, maintaining a pressure slightly above that of the outside atmosphere. If the friction of the air drifts was not sufficient to produce this excess over atmospheric pressure, then doors or baffles were to be adjusted to hold the gases in the interior of the blocks of ore and filling, the intent being to push back the gases into the filling slowly through the mass of ore and filling to the surface, using just enough pressure to make the movement of air from the workings through the filling and to assure that it was not in the reverse direction.

"The system was started and within twenty-four hours the workings operated on were freed of smoke and bad air, and in a few days the heated faces of ore cooled off and became dry. If the fans were stopped a few minutes traces of foul gases and sulphurous acid were perceived; on restarting the fans this disappeared.

"If evidences of fire are noticed in the interior of a section of ground by balancing the air pressure around it by means of the fans and doors, etc., the fire can be held in an extinctive atmosphere when it quickly dies out. Use is also made of this system in attacking blocks of heated ore when the ore faces are quickly cooled off by air currents. The positive plenum system of ventilation then had fulfilled its triple purpose. It supplied the fresh, cool air required by those working in it, it cooled off the heated faces of ore and the permeable nature of the ground enabled us to keep an extinctive atmosphere in the interior of the blocks of ore and filling and prevented the pernicious gases of any smoldering fire from entering the workings."

Hardness of the Diamond.

In an extended treatise on the "Genesis and Physical Properties of the Diamond," read before the British Association, Sir William Cookes says of the hardness of the diamond:

Diamonds vary considerably in hardness, and even different parts of the same crystal differ in their resistance in cutting and grinding.

Beautifully white diamonds have been found at Inverel, New South Wales, and, from the rich yield of the mine and the white color of the stones, great things were expected. In the first parcel which came to England the stones were found to be so much harder than South African diamonds that it was at first feared they would be useless except for rock boring purposes. The difficulty of cutting them disappeared with improved appliances, and they now are highly prized.

The famous Koh-i-noor, when cut into its present form, showed a notable variation in hardness. In cutting one of the facets near a yellow flaw, the crystal became harder and harder the further it was cut, and after working the mill for six hours at the usual speed of 2400 revolutions a minute, little impression was made. The speed was increased to more than 3000, when the work slowly proceeded. Other portions of the stone were found to be comparatively soft, and hardened as the outside was cut away.

I can illustrate the intense hardness of the diamond by experiment. On the flattened apex of a conical block of steel I place a diamond, and upon it I bring down a second cone of steel. With the lamp I project an image of the diamond and steel faces on the screen, and force them together by hydraulic power. I can squeeze the stone into the steel blocks without injuring it in the slightest degree.

The pressure gauge shows 60 atmospheres, and the piston being 3.2 inches diameter, the absolute pressure is 3.16 tons, equivalent on a diamond to 12 square millimeters surface to 170 tons per square inch of diamond.

Although not directly bearing on the subject, I will

introduce the only serious rival of the diamond as regards hardness. It is the metal tantalum, a fine specimen of which I owe to Siemens Bros. A hole had to be bored through a plate of this metal, and a diamond drill was used revolving at the rate of 5000 revolutions per minute. This whirling force was continued ceaselessly for three days and nights, when it was found that only a small depression ½ millimeter deep had been drilled, and it was a moot point which had suffered most damage, the diamond or the tantalum. In another respect tantalum is likely to rival graphitic carbon, as it has rivaled adamantine carbon. Its thin wire is extensively used for filaments of incandescent electric lamps; it shows a much higher efficiency than does the old carbon filament. The melting point of tantalum is about 2300° C., a temperature seldom or never reached in an ordinary lamp.

The Borax Industry.

The borax industry, as a branch of mining, is one of which, despite its value and extent, comparatively little is known, and of which, therefore, current knowledge can hardly be arrived at with any certainty, says the London Mining Journal. The industry is controlled by a Trust of European and American producers, under the title of Borax Consolidated, which, with the exception of the Diamond Syndicate, is probably the most powerful and favorably situated of the combinations which control any important part of the mineral industry. The company was registered in London in 1899, and embraced the consolidation of California interests known as the Pacific Borax & Redwoods Chemical Works, the San Bernardino Borax Co., the important Turkish concessions in the hands of the Borax Co. and the Societe Lyonnaise des Mines et Usines de Borax, with unexpired terms of forty and ninety years respectively, Mear & Green, Ltd., the chief producers of Chili and Peru, with a large number of options, especially in South America. The above list indicates shortly the main sources from which the commercial product, borate of lime, is mainly obtained. The United States is the largest producer, but owing to the great internal demand she is also an importer to some extent. The United States Geological Survey's report for 1903 gives the production as 34,430 short tons, six-sevenths of which is 25% ore. The following are the latest statistics we have of the other main producers, arranged as far as possible in order. Chili is the next in importance after the United States, the output for 1903 being 15,732 tons, which H. D. Hoskold, in his investigations into the position of the industry in South America, estimated at 44%. Turkey probably produces some 8000 to 9000 tons, but there are, of course, no official statistics. Peru gave 5055 tons of borate of lime in 1903, estimated by Hoskold at 45.9%. Italy's contribution in 1903 was 2583 tons.

Bolivia, according to official statistics in 1904, gave 1196 tons, of a percentage, according to Mr. Hoskold, of 38.74%. The output of India, probably the oldest source of borax, was in 1904 only 212 tons. The Prussian production is a similarly negligible quantity, being 135 tons for 1903. Like other portions of the subject the genesis and depositions of the known formations of borax ores does not seem to have been very fully studied, but it is generally believed that the boric acid was liberated from the containing magma, and rising in gaseous form was condensed on contact with air temperatures, being subsequently dissolved by atmospheric waters and carried into the lake and river beds where it is now found as lacrustine deposits. In some cases, also, it is believed that the fissures may have discharged their gases into water basins. In any case, it is to dry and desert tracts that attention mainly turns for such discoveries, and this fact is, no doubt, largely responsible for the success of the control in checking competitors. The distance of the unworked supplies and the desolate character of the country in which they occur make the construction of railways or some similar medium a necessity, so that they are valueless save to a concern with large capital; thus the combine is easily able to secure options over any new district, which is in this way closed to further operations. Deposits exist, and have been worked, in Oregon, Nevada and California; the principal active source of supply in the U. S. A. is the Calico deposit in San Bernardino county. The American industry, moreover, owes its existence largely to the import duty, which under the Dingley tariff is 5c per pound, and against any loss from its removal the great interests of the Trust in South America amply secure them. What arrangements they may have with the administrations of Chili, Peru, and Bolivia, is not known, but apparently they of late years sought to obtain from the Argentine Government an exclusive concession of all occurrences in the Republic, but without success.

The total annual yield of boric acid is estimated by Mr. Hoskold at 22,000 tons. The treatment which the crude ore undergoes varies considerably according to it richness, and the form in which it occurs, the chief being the Stassfurt salt, consisting of pure boracite containing 61% to 62% of boric acid; priceite, 49% to 50%; hydroboracite, 41% to 48%; ulexite, 42%; tinkalzite, 37%, which derives its name from the material shipped to Europe from the Tibetan deposits in earlier days; pandermite (named from the Turkish port of shipment), and colmanite. The Chilian supplies are derived from the districts of Ascotan, Salinas Grandes, and San Pedro de Atacama. The Trust has a line connecting Ascostan with the Antofagasta railway, and the operating costs are given by Mr. Hoskold as follows: Exploitation and drying, 5ls 5d; carriage to Antofagasta, 27s 4d; freight to Europe, 26s 10d; insurance excise, ls 6d; total, 107s 6d per ton, which, considering that the percentage of boric acid is about 44, is believed to be representative of the most favorably situated deposits. With the growth in production, the price of borate of lime has gradually declined. The price in 1864, when the industry started in the United States, was £150, and in 1899, when the Trust began operations, it was £13 10s, falling to £9 at the end of that year. The retail price of borax, according to Messrs. Sacre's table published at the beginning of the present month, was £12 5s 0d The policy of the Trust appears to be to restrict the price to a figure such as not to tempt competitors into the business, while relying on reduction in price to broaden the basis of consumption, though if the figures quoted above are representative there is a good margin of profit. The uses of borax are extensive. It is widely employed in glass, tile pottery and enamelled iron work, as a flux in metalling, and for solder, as a constituent of soaps and washes, in the textile turning and printing trades, as a drying agent in paints, oils, and varnishes, while as a food preservative and in medicine its use is widespread.

The Yak Tunnel.*

One of the most interesting mining enterprises in Colorado is the Yak tunnel in the Leadville district. This tunnel starts in California gulch, about 1½ mile from the center of Leadville, and continues for a distance of over 2 miles under Iron and Breece hills to the Little Johnny shaft of the Ibex M. Co. It also connects with several other well-known properties along the route, among them certain parts of the Iron Silver M. Co. It is used as a drainage tunnel for several mines, as well as for the transportation of ores to the mill and railroad at the mouth of the tunnel. Considerable ore from different companies is now being treated at the Rowe mill, which was erected last winter by the Yak Co. for the handling of their own as well as custom ores. The tunnel was started in 1887, and the present company commenced operations in 1894. The large area drained by the tunnel saves considerable money each year to the owners in pumping plants. The Tucson on Iron hill, which is a portion of the Iron Silver property, is drained through this tunnel. About 6000 tons of ore per month is taken out of the company's mines through the tunnel and 150 tons per day from other companies whose property is tapped or adjacent to the tunnel. An electric motor is used in transporting the ores from the mines to the railroad. The Yak Co. is operating the Cord mine from the tunnel level, and about ¾ of a mile from the tunnel entrance in the Cord ground they have sunk a winze and installed an electric hoist. In sinking the winze the following formation was encountered, which was taken from the drill book of the company:

	Feet.
Limestone	0 to 25
Intrusive porphyry	25 to 27
Blue limestone	27 to 187
Quartzite	187 to 207
Lime contact	207 to 209
White limestone	209 to 219
Quartzite	219 to 222
Ore	222 to 282
Sulphide porphyry	282 to 332
Sulphide	332 to ...

From the surface down a distance of 500 feet the ore is oxidized.

The company has recently installed an Allis-Chalmers 400 H. P. cross-compound engine and Bullock generator, and have left room for a duplicate plant in the same building, which will be installed as soon as needed. From this plant, which is at the mouth of the tunnel, wire has been strung for about 1 mile up the hill to the Horseshoe shaft where transformers are being installed. The electric power from these transformers will be used in hoisting and in operating the electric pumps, which are being installed to pump water from the shafts and winzes up to the tunnel level.

*See Illustration on Front Page.

THE bane of compressed air in expanding engines has been the freezing at exhaust ports, says Page's Weekly. At the Gray Canyon plant at North Amherst, Ohio, this trouble was anticipated and provided for. A large part of the entrained moisture is condensed and collected in the inter-coolers and after-coolers; another portion finds lodgment in the primary receiver. From this point the lines grade to secondary receivers, where the condensation of the entire line is collected and removed through cocks. So perfect is this system for removing moisture that the plant was operated for weeks in freezing weather without reheaters and with no freezing whatever.

Power Required to Operate on Inclines.

All are familiar with the fact that less power is required to lift a load on an incline than vertically, and that more power is required to move a given load on even a very low grade than on the level. The pressure on the rails on any given grade is determined by multiplying the weight of the load—including the car or skip—by the sine of the angle of inclination. Thus a load of one ton on an incline of 30° from the horizon exerts a downward pressure normal to the track of 1000 pounds. The following table was designed to make readily available information of this kind on tracks at any angle up to 36° 31′, and will be found useful to those who have traction problems to solve where the road runs on grades and has more or less numerous curves. The table, with accompanying foot notes, is self-explanatory:

FORCES ON INCLINED PLANES

% of Grade Rise Ft. per 100 Ft.	Angle A	Sine	Cosine	Perpendicular Pressure on Plane per Ton of 2000 lbs.	Stress in Rope per Ton 2000 lbs. Friction 1/40	Stress in Rope per Ton 2000 lbs. Friction 1/32	Stress in Rope per Ton 2000 lbs. Friction 1/25	% of Grade Rise Ft. per 100 Ft.	Angle A	Sine	Cosine	Perpendicular Pressure on Plane per Ton of 2000 lbs.	Stress in Rope per Ton 2000 lbs. Friction 1/40	Stress in Rope per Ton 2000 lbs. Friction 1/32	Stress in Rope per Ton 2000 lbs. Friction 1/25

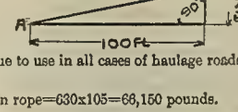
COPYRIGHT 1902

NOTE.—Stresses and Pressures are in pounds.

NOTE.—1/40 should be used in all cases of straight inclines planes.

NOTE.—1/32 should be used on haulage roads moderately curved.

NOTE.—1/25 should be used on haulage roads with sharp curves, and is a safe value to use in all cases of haulage roads likely to be met with up to 1½ miles, on longer roads weight of rope should be added to load.



EXAMPLE.—105 tons to be hauled up a road moderately curved, 30% slope stress in rope=630x105=66,150 pounds.

RULE.—Multiply number opposite grade, and in column headed Friction, corresponding to kind of haulage road by tons to be hauled. Product equals pull in cable to haul load.

History of Pyritic Smelting.*

By ROBERT C. STICHT.

Among the great mines of the world is the copper property of the Mount Lyell Mining & Railway Co, in Tasmania. The general manager of this property is Robert C. Sticht, who was recently elected president of the Australasian Institute of Mining Engineers. In his address to the Institute, upon his acceptance of this honorable office, Mr. Sticht gave a most interesting and valuable history of pyritic smelting. The valuable and interesting data comprise a good-sized volume, and, while it is interesting throughout, space required for articles on other subjects makes it impossible to reproduce the work of Mr. Sticht verbatim. An abstract of the essential features, however, will be presented, and will be found of interest to all who are engaged in or in any way identified with pyritic smelting:

For the purpose of dealing with the subject it will be convenient to divide it into two concurrent heads, and to distinguish, for historical reasons as well as for metallurgical ones, between that branch of the general method of matte smelting, which, until about 1891, has been called "pyritic smelting," and the more recent offshoot of the latter, which, by distinction, may be called "pyrite smelting." The nature of pyritic smelting was clearly defined by Dr. John Percy in 1880, and his interpretation may be accepted as well known.

Whereas "pyritic smelting" is fairly ancient, "pyrite smelting," on the other hand, is a distinctly novel and modern achievement. Both are blast furnace operations, using pyrites as a collector. But, while pyritic smelting demands carbonaceous fuel in order to flourish, true pyritic smelting suffers with its use.

The historical course of development has broadly been, first, pyritic smelting; then pyrite smelting; and lastly, partial pyrite smelting. Yet the interval of time intervening between the second and third is extremely short compared with the long step from the beginning of pyritic to pyrite smelting.

As remarked above, the introduction of pyritic smelting took place in 1555, and to Barthold Kohler belongs the credit of having first conceived the notion of using iron pyrites for the special purpose of acting as a collector of the precious metals, without the use of lead, or the presence of copper in the furnace. His endeavor was to make what is now called an "iron matte."

For several centuries progress in pyritic smelting was slow and but little advance was made. Improvements were made in the blast and in the tuyeres. Except in rare instances, all smelting during this long period of years was done with "noses." Even down to forty or fifty years ago the proper method of charging the furnace to obtain the correct and only suitable length of nose before the tuyere, together with the correct inclination of the tuyere and blast nozzle, was a matter for the most serious differences of opinion in European metallurgical circles.

In the twenty years preceding 1827 pyritic furnaces had risen in height from 10 feet to one 24 feet, but still had usually but one tuyere, with a double set of bellows. Wooden box or square piston blowers replaced the triangular wooden blowers at Freiberg from 1823 to 1827, but all of the important works had cylindrical piston blowers by about 1831.

Coke was first tried in Freiberg in 1818. * * * The results were immediately successful, and it was observed that the products came out purer and cleaner. * * * In consequence of coke, the year 1823 saw a pyritic furnace run seven weeks for the first time at Freiberg, and later the same year a campaign of twelve and one-half weeks was accomplished.

Of considerable interest, and of some bearing on pyritic work, were the facts established by Lampadius in connection with the application of a heated blast in pyritic work. J. B. Neilson had successfully introduced hot blast in iron smelting in 1828-9, and Lampadius recommended its use in 1831, but actual trials were not made with it at Freiberg until 1836 and 1837. They were then carried out not only in connection with the pyritic smelting operation, but with all the rest where a heated blast appeared of possible service.

Hot blast was given up at Freiberg after a few years, and in the other localities it also appears to have dropped out of use the same as at Freiberg, and probably the most notable instance of its permanent retention, in pure pyritic work, is Kongsberg. Here, however, it dwindled down, in course of time, to a mere hollow tuyere arrangement, in which the blast circulated prior to entering the furnace.

The number of tuyeres began to increase, and three or four became common in due course—i. e., about the middle of the nineteenth century. The "great furnace" at Freiberg, built in 1845, after a Swedish model, had three tuyeres. In Sweden pyritic smelting furnaces with three and four tuyeres were in use, and the furnaces 18 and 24 feet high, while campaigns lasted eight to ten months.

*Abstract of Proceedings Australasian Inst. Mining Engineers.

With the spread of smelting operations in America since the sixties, the easily transportable rotary blowers found a rapid application to the smelting of metals other than iron, the older Root's blower, however, giving way, for a time, to the Baker. The water tuyere gradually developed into the water jacket, and from that time on the furnace construction was to receive a prodigious furtherance in perfection of detail. In connection with the progressive movement then established in the United States, which has since quite dislocated the center of merit in blast furnace management by shifting it from Europe to America, not the least signally useful and convenient invention is that of the independent—i. e., outside—movable forehearth, which is so typical of Yankee practicality.

Pyritic smelting received a check which undoubtedly injured its advancement. It occurred at Freiberg, the very home of its birth, where, after careful comparative trials, extending from 1847 to 1852, the whole scheme of pyritic work was altered by casting aside the blast furnace for the purpose, and substituting the reverberatory. The incentive to the change was the low capacity of the blast furnace, the reverberatory trebling the figures obtained by its rival.

The middle of the nineteenth century, among other advances pertaining to metallurgy, was characterized by a renewal of the interest in combustion and oxidation among the chemists and physicists, and the foundations were laid for our present and future knowledge of thermo-chemistry at the hand of extensive study. In the less abstruse and more immediately useful field covered by the purely chemical side of the reactions taking place in slow oxidation phenomena, one name, that of Plattner, still stands alone as that of the paragon of painstaking investigation and close research. To this day his work on the roasting processes is the authoritative one and has received no important modification, although published in 1856

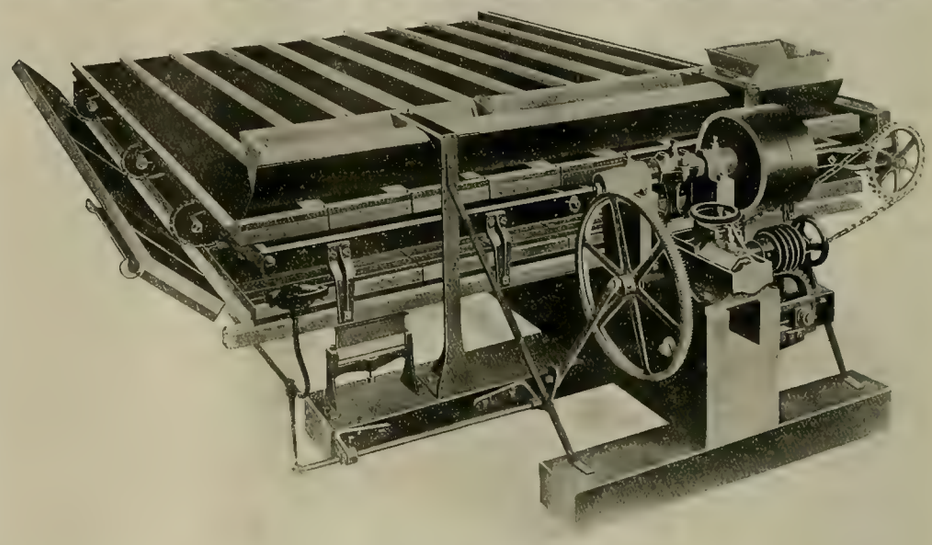
However, as far as the practical utilization of the oxidation idea is concerned, its most magnificent application was not vouchsafed to a metallurgical or analytical scientist, but to a man whose modicum of early scientific training had left him so untrammelled by considerations of philosophical exactitude as not to make him shrink from announcing to the world of science that he had found a method of making wrought iron and steel "without the use of fuel." This was Sir Henry Bessemer. The first Bessemer patent was taken out in October, 1855, but the details were first broadly published in the celebrated article read at the Cheltenham meeting of the British Association in 1856. Thus the principles of slow and the surprising effects of rapid oxidation were first given to the world in the same year. Of the two it must be said that the revelations of the latter have had by far the farther-reaching consequences and have revolutionized the whole domain of metallurgical thought, or, at all events, bestowed upon what might indefinitely have remained mere speculation the endorsement of the most concrete and material feasibility.

In 1866 the management of the steel plant in the Bogoslowsk district, in the Ural mountains, at the initiative of the official head of the district, Semennikow, successfully carried out a series of tests in the local Bessemer apparatus to work up copper mattes from the adjacent copper works to a richer metal, or black copper. It was this Russian engineer, therefore, who demonstrated the actual practical feasibility of the expected reactions; but, for the present, the efforts did not achieve the production of metallic copper, as was hoped. Fifteen trials were made with rather small quantities, and, although the experiments remained inconclusive in the chiefly desired respect, still the experience demonstrated that, for substances that contain them in sufficient quantity, iron and sulphur are as effective fuels as the constituents of pig iron, which are burned in the Bessemer process proper, are in its particular instance.

(TO BE CONTINUED.)

The Wilfley Slime Table.

The No. 2 Wilfley slime table illustrated herewith has several improvements over the old style table. The movement is self-contained and mounted upon a strongly ribbed base made of close grained cast iron.



Wilfley Slime Table.

The frame is securely bolted to the girder support, doing away with the lost motion. The table proper, or deck, consists of a number of shallow troughs or trays, having the bottom of each covered with duck or heavy canvas, which is dipped in a specially prepared paint before putting in tray. These troughs are arranged side by side and attached to link belts, forming in the whole a large belt moving across the table very slowly, taking about forty-five minutes to make one complete revolution. While this belt or series of trays is slowly moving across the table, from left to right when standing facing the movement, a lengthwise, oscillating motion is given to the deck by the movement head. The revolution of the belt is produced by sprocket wheels and a link belt driven by means of a worm gear and shaft, geared to the head motion eccentric shaft.

The oscillating motion, according to the manufacturers' statement, carries off the particles of silica and gangue, while the smaller particles of ore, concentrates and slimes remain in the cavities in the canvas bottom of the trays and pass slowly over the side of the table, returning on the underside of the table, and, as they pass over a concentrates box, the values are sprayed by a small stream of water and washed into the concentrates box. The machines are fully explained in Bulletin S—8 of the Mine & Smelter Supply Co., Denver, Colo., who are sole owners and manufacturers.

Working Costs on the Rand.

A contributor to the London Mining Journal writes as follows on mining costs on the Rand:

An impression seems to be gaining ground that all is not being done by the mine managers to reduce the working costs. It is undoubtedly a fact that, considering the cheaper stores, explosives, and fuel, the working costs do not show the advantage anticipated, nor do the lessened railway rates show any diminution in the cost of living. Stores and explosives are undoubtedly cheaper, but an instance was seen the other day, where the whole of this advantage apparently went to the white employes. There has always been a liberal consumption of stores on the Rand, and until every item is closely watched there is likely to be wastage. As for the reduction of railway rates and the connection of the mines by railway sidings bringing about an appreciable reduction in the cost of fuel, the unduly high charges placed upon the use of the new sidings have to a large extent neutralized the good results anticipated. Then, undoubtedly, native wages are high, and the same may be said of the wages at present paid to the Chinese; but it is to be hoped that, as they become more skilled, this difficulty will disappear. As the result of the lengthened scarcity of unskilled labor and the attempt to employ poor whites, more money is being paid away in white wages than formerly, while the skilled white employes are earning as good wages as formerly. If the matter be closely examined, it will be seen that no definite attempt appears to be made to reduce working costs, and until this is taken more thoroughly in hand, the high wages, coupled with the fact that lower grade rock

is being treated than was the case before the war, cannot help but make themselves felt in the shape of lessened profit.

Undeveloped Resources of the Sierra Nevada.*

There is unusual activity in the high Sierras of California the present summer. From several localities, from Tulare county on the south to Plumas county on the north, comes the news of energetic search for new mineral deposits, and stories of ample reward for these efforts. The Sierra region is known to be rich in minerals, both precious and base, but of late years comparatively little attention has been given to the development of these resources. The ore deposits are in many cases large, and the grade of ore is not too low to allow a good profit if the mines be properly equipped and managed, though the difficulties attendant upon mining operations in that high region are greater than in the warm low foothills to the westward, and even greater, in some places, than in the camps situated out on the desert in the Great Basin to the eastward of the mountains. The peaks are from 12,000 to 13,000 feet or more in height, and few of the most promising mines are below 8,000 feet, while the greater number are at 10,000 feet altitude or higher.

The snowfall is heavy, the winters are long, but when adequate means for transportation is provided there is apparently nothing that need prevent a proper stocking of the camp during the summer months with supplies to last throughout the succeeding winter. In Colorado this is nothing unusual, and in many districts of that State nothing better is expected or apparently wanted. Both Leadville and Cripple Creek are more than 10,000 feet above the sea, and many small towns in Colorado are considerably higher; yet climatic conditions there interpose but a small obstacle to the development of the mines. The present season's work in the Sierra Nevada of California will probably be a long step toward the reopening of the idle mines of that elevated region, and in the development of new discoveries. The accompanying illustrations give a good idea of two types of scenery in that part of California. The rugged, treeless slopes face the Great Basin on the east side of the range, and the gently sloping timbered ridges are on the west side. Mines are found under both conditions.

A Glacial Lake in the High Sierra, California.

In the Mineral Belt of the Sierra Nevada.

*See Illustration on Front Page.

With the approach once more of cold weather in the northern States, the usual number of powder-thawing accidents may be anticipated.

THE PROSPECTOR.

Those sending rock and mineral samples for determination must send their names and the locality from which the samples were obtained, otherwise it will be impossible to identify them. A great many samples are received, and many of them bear no name nor letter of explanation. With these nothing can be done.

The samples from Burnt Ranch, Cal., are: No. 19. Gouge produced by the crushing and movement of country rock; the original rock apparently consisted largely of feldspathic and magnesian materials. No. 20 is serpentine. No. 21 is a much altered feldspathic rock.

The black, flat rock from Hardy, Or., marked J. A. W., is a piece of foliated clay slate. The prismatic colors are due to the partial oxidation of a small amount of iron and copper sulphide present in the rock.

The rock from Lyon county, Nev., is not of unusual weight. It is a much altered dike rock, which accounts for the mass having "walls." It should be assayed for gold and silver. It may be, however, that the values, if any, occur in the flint-like quartz forming the hanging wall. The dike and walls should be assayed wherever they can be cut in search of a pay shoot. In flinty quartz the gold is likely to be extremely fine and possibly could not be detected by panning, which would render assays necessary. The brown mineral in some of the rock is limonite, an oxide of iron, due to decomposition of iron sulphides.

The rocks from Clifton, Ariz., are principally carbonate of lime (limestone).

The rocks from Liscum, Ariz., are very much altered, but were apparently originally rhyolite. It is not likely that large bodies of copper ore will be found beneath this outcrop—at least, the rocks give no indication of it. They should rather be tested for gold and silver.

The rocks from Grants Pass, Or., are: No. 1. Diabase. No. 2. Diorite, with some iron sulphide.

The greenish rock specimens from Lake City, Colo., are sandstone, consisting chiefly of crystals of magnetite cemented by grains of glauconite (iron silicate). By crushing, the magnetite might be recovered by either water or electric concentration.

The red mineral from Winkelman, Ariz., is earthy hematite, with some calcium carbonate. No. 2 is amphibole (hornblende).

The black mineral specimen from La Sal, Utah, on which there is a coating of green and blue copper carbonate, is apparently a volcanic scoria, or sort of pumice, which has included small pebbles from the sands over which it flowed. The presence of the copper can only be accounted for by the assumption that there are or have been waters carrying copper in solution, and the copper has been precipitated in and on this rock. This is not an unusual phenomenon. At Copper Basin, Yavapai county, Ariz., copper carbonate has been deposited in acres of gravel in this manner.

The lead-colored mineral in sample No. 1 from Cerrillos, N. M., is molybdenite (sulphide of molybdenum), and the bright yellow metallic streak is pyrite (iron sulphide). No. 2 is largely kaolinized feldspar, with bunches of "wad," an impure ore of iron and manganese oxides.

The rocks from Pearl, Idaho, have been classified as follows: No. 1 is chert (flint) carrying considerable very fine iron sulphide; it may be gold-bearing, but would have to be crushed very fine to liberate the pyrite and gold. No. 2 is so much altered as to make positive identification impossible; it resembles a devitrified volcanic glass or pearlite and appears to be breaking up into rounded grains. No. 3 is composed of rounded grains of quartz and chalcedony, cemented by carbonate of lime—a fragmental rock. No. 4 is volcanic ash. No. 5 is similar to No. 3. No. 6 is very much like Nos. 3 and 5, except that the cementing material in No. 6 is iron instead of lime. No. 7 is a quantity of quartz pebbles. No. 8 is a coarse sand rock composed of rounded quartz grains and cemented by clay and iron. If these rocks and sands contain gold, the question of being able to extract the gold by the cyanide process is one which must be determined by experiment. This question can never safely be answered without making a test.

The small mineral specimen from Las Cruces, N. M., is apparently a variety of obsidian (volcanic glass).

The rock sample from New Bridge, Or., is metadiabase and is evidently an ancient breccia, as it presents a semi-fragmental appearance, consisting of various sized pieces of angular greenstone, recemented by the later magma of the rock mass. It is an interesting rock and sometimes forms the walls of gold-bearing veins.

The Ventilation of Mines.

NUMBER VIII.—CONCLUDED.

FUMES FROM THE CYANIDE PROCESS.—From time to time there have been many complaints as to vitiation of the air of mines by fumes arising from the tailings from cyanide treatment very commonly used for filling stoped ground, and some of the witnesses heard by us were of opinion that the use of these should be absolutely prohibited; others thought that the tailings should be stored at surface till thoroughly dry and freed from cyanide. On the other hand, it was claimed by many managers that if the sands were well washed and not left too wet they may be used underground with perfect safety. The question is a very important one. Huge heaps of tailings have to be got rid of in some way at the big mills, and it is not always possible to get suitable dumping ground for them close to the mills, so that they may have to be carried some distance before they can be stored. If they are not used for filling, the expense of removal becomes a perceptible item in the costs sheet, and amounts to a very large sum of money annually in mines with a large output. At the same time the spaces underground from which the ore has been extracted must be filled with "mullock" for safety, and in most of the larger mines of the State there is not nearly enough filling material obtained in the course of development work to fill the stopes, and if tailings may not be used, "mullock" has to be quarried and sent down into the mine, again leading to further expense. The tailings, apart from the fumes arising from them, are a highly desirable sort of filling, running well in the passes, easily shoveled, and packing the ground admirably. The prohibition of their use should therefore, be contemplated only on demonstration that they are a serious danger to health. The occurrence of two fatal accidents from fumes given off from tailings used for filling has been recorded, one causing the death of one man in the Paddington Consols mine and the other the death of two men in the Jacoletti mine. In the first case three other men were also affected, but recovered. Witnesses have also informed us of numerous cases of men being turned sick by the fumes from the tailings, though not made seriously ill. In both the fatal cases the sands were new and damp, and the ventilation became blocked, so that the fumes could not be removed. The smell s usually very noticeable, and the men working find a bitter taste in their mouths. It can easily be understood that if the ventilation is bad the poisonous gas may accumulate to a dangerous extent, even if there is only a very small percentage of cyanide present. As the decomposition of potassium cyanide is mainly due to the carbonic acid of the air, it seems likely that in a badly ventilated place, where the amount of carbonic acid rapidly rises to, say, ten times the normal percentage, and the humidity is considerable, the liberation of hydrocyanic acid will be correspondingly more rapid. It would seem from these considerations that even well-washed tailings might become dangerous in a badly ventilated place. Where the ventilation is good there appears to be practically no danger, which indicates that when these sands are to be used the first provision to be made is that the place should have a good current of air passing through it.

We would, therefore, recommend that tailings should not be used for filling (1) in a wet state, nor (2) when they contain more than .01% of their weight of cyanides calculated as cyanide of potassium, nor (3) in any place in which there is not a current of air passing freely In some cases where it is not possible to thoroughly wash the sands, and a larger amount than .01% of cyanide of potassium is left in them, it would be necessary to expose them to the air at surface for several months before using them, until the cyanide is reduced below the prescribed limit. The stacking of the tailings at surface prior to use as filling certainly necessitates some expense that would be saved by putting them direct into the mines, but we consider that the danger is so great and real that this expense must be borne rather than that there should be any question of using doubtful sands where they might cause loss of human life.

RISING.—Of all mining work, the operation of "rising" from a lower level to a higher one is generally regarded as most likely to lead to injury of health, and among the workers' witnesses who came before the Commission there was a very general desire evinced to have the height to which rises might be carried limited by law. The relative danger of accidental injury in this sort of work, as compared with other kinds of mining operations, is a question outside the scope of our Commission; but, from the standpoint of ventilation, we have given it considerable attention. Most of the mining managers examined were against high rises, partly on account of the health of their men, partly because the working difficulties, and, consequently, the costs, increase with height. The opinions expressed both by managers and men as to the height which should not be exceeded were very various, from 20 feet above the level to as much as 200 feet being considered fair limits. The most general opinion appeared to be that rises should not be carried up more than 50 feet, unless special circumstances made a greater height unavoidable. A great deal of difference of opinion was also expressed as to the best method of construction of rises to ensure both ventilation and safe working, the ordinary practice in this State being, as a matter of fact, to go up with stages on "spreaders," without any division of the rise. The air from the rock-drilling machines is in these cases usually relied on entirely for ventilation. In some of the mines strong platforms or pent-houses are made at intervals, alternately on each side of the rise, leaving a small open space in the center for the dirt to be thrown down. This, evidently, is a method peculiarly well adapted to preventing any natural ventilation. The workers' witnesses were almost unanimously strongly in favor of the "box" system of rising (that is, constructing the rise in three compartments, with the center one filled with broken rock), and many under-managers and managers supported them. We saw only three such rises, however, in our visits to the mines. The advantage is that, when there is a current passing through the level beneath, by putting a door under the central compartment of the rise, the air may be sent up one side of it and down the other, thus maintaining good ventilation. It also affords greater safety in working, and there is less liability of the timber being knocked out by the blasting than with the ordinary spreaders. Some managers considered these boxed rises were more expensive than the ordinary type, but others thought there was very little difference in point of cost, the advantages of the box, and speed gained in the work, being held to make up for the cost of the timber used in it. We were unable to get any direct comparison of cost. We are, however, of opinion that the advantages of the box in ventilation and safety of working are very great, and recommend that its use should be compulsory in all rises intended to be over 20 feet in height. If the box is well constructed, and provision made as well for mechanical ventilation in case of the compartment for sending down the dirt becoming choked, there seems no reason why rises should not be carried to any desired height, and for high rises the cost with a box would almost certainly be less than without one. The method of rising diagonally on the plane of the lode, instead of directly up it, so as to have a rise with an inclination of not more than 45°, instead of whatever may be the underlay of the lode, has also been brought to our notice; but while it would, undoubtedly, tend to greater safety from accidents, it does not appear to have any advantages from the point of view of ventilation.

The analyses made by Mr. Mann of the air in rises show clearly that they are much worse ventilated than most others parts of the mines, the tests proving to be often very hot and foul. This is only to be expected, as the heat of the men's bodies, of their candles, and of the rock after blasting, all goes to warm the air in the top of the rise, and this warm air cannot escape except by diffusion unless a strong air current is sent through the rise. The tendency is for a stagnant body of warm air to remain in the top of the rise, receiving all the vitiation, and being removed only slowly by diffusion. There is a popular misconception as to the behavior of carbon dioxide gas in such places which should be corrected, namely, that, being half as heavy again as air, it will fall down from a rise. This would be so if a quantity of the pure gas were liberated all at once in the place; it would fall directly downwards. But if instead of pure gas it was a mixture of say 3% of carbon dioxide with 97% of air, both thoroughly mixed together, there would be very little tendency to fall, as the specific gravity of the mixture would be very little greater than that of air. A rise in temperature of 9° F. would make its specific gravity the same as that of air. With percentages of carbon dioxide in the mixture of not more than one-tenth of the example taken, as is the usual practical condition, a very slight rise in temperature prevents the vitiated air from falling at all. The carbonic acid formed by breathing and by burning of candles is so dilute, and produced so slowly, that it becomes entirely diffused at once into the surrounding air, and even that produced by explosions is much diluted when generated, becomes greatly mixed with a large volume of air at once by the action of the explosion, and is highly heated, so that it does not fall down the rise, but remains at the top and is only removed by diffusion or ventilation.

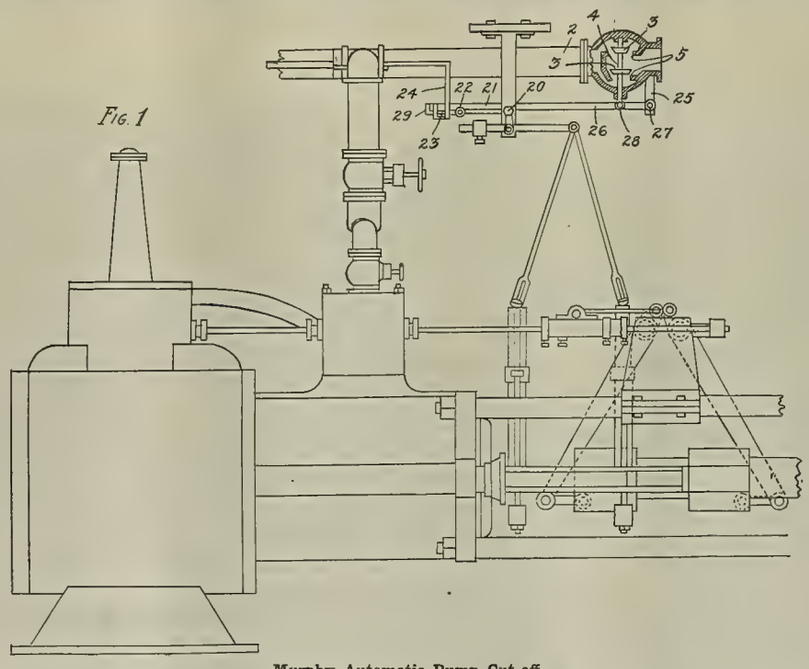
We would not, however, recommend any specific limit to the height of rises, as high ones are not infrequently unavoidable, and such a restriction would operate very injuriously to economical working in such cases. We think that the use of the box and mechanical ventilation, and the enforcement of the previously recommended standards of allowable temperature and purity of air, would remove the objections to rising.

WINZES.—The ventilation of winzes is usually simple, the cool air from the levels going down and the warmed air coming up. Several bad accidents, however, in winzes show that the removal of fumes after blasting has sometimes been unsatisfactory. So long as natural ventilation is alone relied on there is liable at any time to be a cessation of air currents entering winzes, and then they may be very dangerous to go into after firing. We think that in all winzes provision should be made for some effective mechanical means of ventilation.

Automatic Pump Cut-off.

Herewith is illustrated the Murphy automatic pump cut off, which device has been in use at the Resurrection mine, Leadville, Colo., for ten months. It is used on a Knowles compound condensing pump, pumping 225 gallons per minute, a lift of 750 feet. The shaft where the pump is located is not being worked, all the work of the mine being done at another shaft, ½ mile away. To run this plant, two firemen are required, one on day shift and one on night shift. Twice a day, every morning and evening, one of the men employed at the other shaft, taking care of the machinery about the property, goes down this shaft and oils the pump. The manufacturers say that the pump runs by itself all the time, and that it is safe with this attachment to let it do so. "During the time it has been in use, the pump dropped a suction valve; it stopped immediately, doing no harm. The large cast-iron 'Y' at the bottom of the water column burst when no one was there; the pump stopped and did no harm."

FIG. 1



Murphy Automatic Pump Cut-off.

The illustration is a side elevation of a double-acting pump showing the automatic cut-off in accordance with this invention arranged in operative relation with respect to the pump. 1 denotes the double-acting pump, 2 the motive fluid supply pipe which is provided with an automatically operating cut-off in the form of a double valve, as at 3, the stem 4 of double valve projecting below the pipe 2. A pair of seats 5 is provided for the valves 3.

When the device is used in connection with a double-acting pump, a pair of supports is provided; if used in connection with a single-acting pump, but one support is necessary. The device is manufactured and sold by the Carnahan Manufacturing Co., Denver, Colo.

Placer Mining in Alaska.*

NUMBER IX.

DRIFTING IN THE FAIRBANKS DISTRICT.—As has been stated, the only mining practiced at Fairbanks is creek mining. In the open season, although the bulk of the ground can be worked by drifting, a smaller proportion is workable by open cutting. By far the larger portion of the ground must be worked by drifting on account of the depth to bedrock and, in many cases, the thinness of the pay. The ground is in the main frozen, but thawed streaks occur. The gravels are of the angular and subangular character, which marks all the gravels deposited in recent time in the northwest. The angularity is more pronounced than in the Birch creek district or the Klondike.

One characteristic feature of the Fairbanks gravel has an important bearing on the method of thawing the frozen gravel. This is the fact, that while the layer of so-called muck is comparatively thin, from 2 to 7 feet in the workings on the creeks themselves, exclusive of the slopes, the gravels, which are from 6 to 15 feet in thickness, do not carry pay throughout their section, but only in the lower part. The pay is sometimes as thin as 6 inches in the gravel, and rarely exceeds 3 feet. It is then frequently necessary to take only a portion of the gravel down, and to run the drifts as low as possible, i. e., not to exceed 3½ feet. To do this economically, and so that the top and barren gravel will not be continually caving and falling during the drifting, the ground must either be timbered or the method of steam thawing must be abandoned. Another reason why the method of steam thawing has a limited application in the Fairbanks district is the fact that the gravel is very argillaceous in its pay portion, and the thawing and drying with the steam result in the baking of the ground. Thus the gravel which was frozen becomes in its dry state cemented, and the difficulty of getting it out is not avoided, but only lessened.

Thawing by means of hot water driven through a force pump and conducted to the bank by means of cotton hose and piped against the bank by means of a small fireman's nozzle is the most successful method which has been so far tried to thaw ground under the above-mentioned conditions. As regards the heating of the water, the system adopted at Fairbanks is to conduct the exhaust steam of the pump back into the suction of the pump as it draws water from a sump alongside of it. This has been found more effective than simply turning the exhaust pipe directly into the sump itself. The water used is sometimes supplied in sufficient quantity from the mere seepage from the ice mixed with the thawed gravel. But sometimes it will have to be introduced into the pit in small quantity. On the other hand, especially where thawed streaks occur naturally in the gravel, the water must be pumped out. This is done by the same pump used for hydraulicking, without changing its position.

The method of thawing by hot water piped against the bank has two advantages. The strongest appears to be the fact that gravel thawed by this method can, as it were, be selected in the face, and no higher gravel than may be profitable need be taken down. The portion of the gravel above the part taken down remains solidly frozen, and consequently the roof of the drift or wide stope does not cave any worse than does the roof of solid muck in drifting operations, where all the gravel in its complete vertical section is extracted. Another advantage is that the gravel is moved from its original position further than by steam, and if it contains clay the clay has less opportunity to bake and cake than by steam thawing, and the amount of hard work in picking down is lessened.

A serious objection to thawing by hot water may justifiably be raised in cases where the bedrock consists of large slabs of schist, into which the gold sinks from 1 to 4 feet and even more. In such a case the water cannot be piped to reach all the frozen gold-bearing material. Although I am not aware that a combination of the hot-water and steam-thawing methods has been tried in such a case as the above, it seems not impossible that such a combination would be the most economical. On the other hand, where the bedrock consists of a finely comminuted schist or softened, thoroughly rotten rock, even should the gold be found in it to the depth of 2 feet, there can be no valid objection to the hot-water hydraulicking method. In the Nome district of Seward Peninsula, where the hot-water method was tried, it was found that the water finally became too thick with sediment to be used in the pump, and the system was abandoned.

A minor recommendation for the use of the hot water method is the fact that all the unpleasantness of the steam method, which fills the workings with steam, creates dampness, etc., is obviated, and the walls and roof of the drifts are dry, while ditches cut in the bedrock on grade to the pump sump can be so cut as to prevent the floors from being wet. The obscurity of the air in the workings by steam, especially in the early part of the day shift, is frequently a source of danger, as the roof can not be watched so closely as it could were the air clear, and consequently slabs of the roof that are ready to fall can not be easily seen, so that the liability that men will be crushed is greater.

I should especially recommend the method of hot water thawing to the consideration of the miners of Cleary and Pedro creeks, while on Fairbanks creek, as hitherto developed, the method of thawing with steam points seems more applicable.

In the Fairbanks district shafts sunk for work in the summer time are in nearly all cases timbered, either wholly or partially. In very deep shafts—as, for example, on the left bank of Cleary creek, near the junction with Chatham, where 40 feet or more of solid muck is encountered—timbering does not appear to be always necessary throughout the whole of the shaft. The muck forms a wall which resembles in its consistency a wall of solid ice, and in working throughout a season of four months, with the shaft in constant use, there will be little caving of the walls. All shafts that extend 20 feet or less, however, especially where gravel composes half or more of the section—shafts intended for working out a block of ground, conducting steam connections, pump connections, and connections for hoisting—should be securely timbered.

In view of the local conditions, the following method of timbering appears the most satisfactory: After the hole is sunk to the required depth by thawing, a square set with 6-foot centers—or should the shaft be 4 by 6 feet, of this dimension—is put in at the bottom. Three-inch pole lagging, with cross sets of 6-inch timbers inside at 6-foot intervals, is carried up to the collar. Inside the sets 6 or 12-foot poles, 3-inch, are nailed in the four corners to the cross sets. Moss is laid up outside the pole lagging, as dry as possible, and packed against the gravel or muck walls. In cases where it is impossible to sink without timbering as the shaft is sunk, the timbering is carried down and the lagging is driven as each set progresses, the square set being put in at the bottom on the completion of the shaft. Shafts timbered in this manner have been found to stand for periods of from one to two years—as long as the work in the Fairbanks district has been in progress—and there is no reason why they should not stand much longer. Timbering of this sort can be done for the most part with the ordinary cordwood delivered for fuel, and this is much the cheapest method available.

The cribbing method is sometimes adopted, accompanied by the same packing, with moss outside the cribbing. It is, however, more expensive, and in a shaft of considerable depth is much more likely to get out of plumb in this frost-ridden country.

In the Fairbanks district it has not yet been found necessary to timber the underground workings to any great extent. The main runway, if it be used for the whole season or for a period exceeding a month, should be timbered for safety. Six-foot sets of posts and caps only, with lagging over the roof, are generally sufficient. Pole lagging is cheaper and more advisable than split lagging. The caving system, working always toward the shaft, allows the faces to be carried forward without timbering the stopes. The elaborate timbering methods necessary in the Klondike benches and in many parts of California in drifting operations are happily not needed in this portion of Alaska, and are not likely to be required in any extension of the Tanana area. No case has been seen in the operations, as thus far developed, where false sets were carried in taking out gravel. When the operations at Fairbanks become more extensive, however, and drifting is carried on more systematically with wide faces, it is very likely that the workings will require timbering. At present it is not possible to give the cost of this work, as the figures were not obtainable.

(TO BE CONTINUED.)

*Bulletin 268 U. S. Geological Survey.

Electric Locomotives.

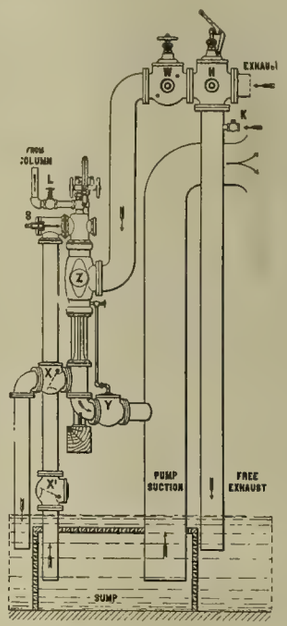
The New York, New Haven & Hartford Railroad will put twenty-five alternating current single phase electric locomotives on the New York end. It is the first order for electrical apparatus purchased by them as a part of the scheme for the electrification of their entire road between New York and New Haven, Conn.

Each locomotive will have a total weight approximating 78 tons, and will be equipped with four 250 H. P. A. C.—D. C. gearless motors of the Westinghouse type, the motor armatures being built directly upon the axle. They will be equipped with the latest type of unit switch system of multiple control for A. C.—D. C. operation. The locomotives will be so arranged that they can be connected two or three in multiple on a train. Each locomotive will have sufficient capacity to haul a 200-ton train (exclusive of locomotive weight) at a schedule speed of 26 miles per hour for the local service on the New York end, and will have a capacity for hauling a 250-ton train at a maximum speed of 60 to 70 miles per hour for express service where there are fewer stops. Locomotives are designed to collect direct current both from a third rail on the side of the locomotive and from an overhead conductor, and alternating current from an overhead conductor.

This is the first large order for electric locomotives awarded in open competition by a steam railroad in this country, and appears to mark the beginning of a new era in railroading.

A Universal Condenser.

The Schutte & Kœrting universal condenser is shown in accompanying illustration: Z represents condenser; W water-check valve; H free exhaust valve; S basket strainer; Y automatic discharge valve; X discharge relief valve; XI suction check; K air check. This arrangement is deemed desirable in deep mines having a great discharge height and consequently greater volume of exhaust in proportion to the volume of water pumped. Under these



Universal Condenser.

conditions, if discharge from condenser were returned to sump, the temperature of sump water would increase, causing annoyance and damage to the timber and detract from the effectiveness of the condenser. By discharging direct into the suction of the pump, the warm water is removed as it is produced and the sump water remains cool. The danger of having steam enter the pump through accidental stoppage of pump or condenser (and thereby destroying the valves and otherwise disturbing the action of the pump) is intended to be eliminated by the automatic action of discharge valve Y, which closes when vacuum in condenser is destroyed, while condenser is free to re-start through check X. And as soon as condenser resumes its action valve Y will open automatically diverting the discharge from the condenser again into the pump suction. Schutte & Kœrting, 702 Security Building, Chicago, are the designers and manufacturers of several condensing or recooling systems.

THE scientific investigators of Polytechnic University of Vienna, Austria, have devised an apparatus to be utilized in entering mines filled with smoke, deadly gases or otherwise dangerous to human existence. This apparatus is portable and may be carried on the backs of members of rescue crews, firefighters or others, and contains the chemicals necessary to generate a liberal supply of oxygen for a considerable period. It is based upon the principle of producing the oxygen required for breathing by means of the exhalation products themselves, by filtering them through a layer of sodium potassium peroxide, whereby the exhaled products—carbon dioxide and water—are absorbed. There are two types of this apparatus, one for constant use while at work and the other for use in the moment of danger. The first type will support life in an atmosphere which is wholly irrespirable for about an hour, thus giving the miner sufficient time to escape from the impending danger. Briefly the apparatus consists of a frame provided with a hose, mouthpiece and a bag sufficiently large to hold a box which contains the layer of sodium potassium and the necessary filters. Equipped with this apparatus, the miner places the breathing tube in his mouth and clamps a spring pin to his nose to prevent breathing of the vitiated air, and, breathing naturally through the tube, he goes to the rescue of those who are in danger. Without doubt, apparatus of this kind may be found extremely useful, and, if found to answer the purpose for which they were designed, should be promptly adopted by mining companies everywhere.

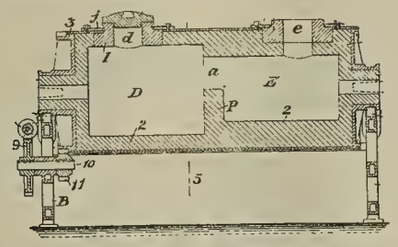
WITH mechanical stokers the poorer grades of bituminous coals can be used, and a higher efficiency of the boiler obtained. It is customary to use with the stoker the poorest and cheapest grades of slack coal obtainable, and the resultant saving over hand firing with run-of-mine or lump coal is apparent without considering the higher efficiency.

Mining and Metallurgical Patents.

PATENTS ISSUED SEPTEMBER 26, 1905.

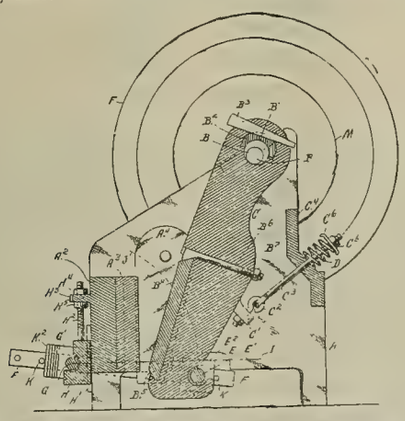
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

SMELTING OR MELTING FURNACE.—No. 800,148; A. B. Griffen, Verona, N. J.



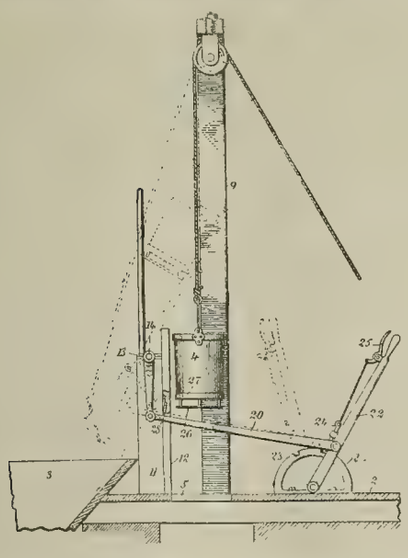
Furnace comprising tiltable body provided with two chambers arranged in horizontal line, one chamber constituting preheating chamber, and other augmenting chamber, vertical partition between two chambers having eccentric opening for establishing communication between chambers for passage of flame or gases when furnace body is in melting position and for establishing communication between chambers for passage of molten metal from preheating chamber to augmenting chamber and for closing off communication when furnace body is tilted for pouring.

ROCK CRUSHER.—No. 800,278; J. H. Elspass, Denver, Colo.



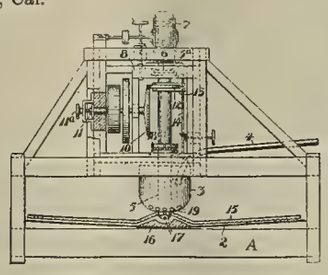
In rock crusher, combination with suitable frame and fixed jaw, movable jaw, means for imparting circular motion to one end of movable jaw, means for causing other end of movable jaw to move on arc whose center lies beyond fixed jaw, and means for adjusting center of arc in line parallel with face of fixed jaw.

BUCKET DUMPING DEVICE. — No. 800,449; J. C. Kirsch and J. J. Hartman, Granite, Colo.



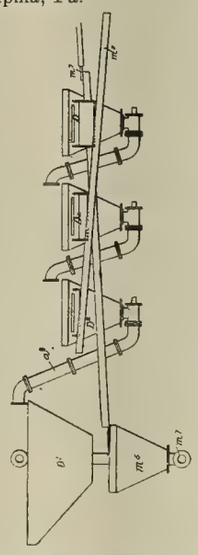
In bucket dumping device combination, pivotally supported bucket holder, means for holding same in inclined position, bucket adapted to descend upon bucket holder when held in inclined position, holder having hooks at lower extremity thereof, and bucket having ring adapted to engage hooks to form point of rotation to dump bucket.

CONCENTRATOR.—No. 800,379; H. L. Lightner, San Francisco, Cal.



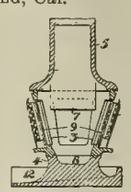
In concentrator, horizontally supported tank having peripheral discharge openings, means for supplying tank with pulp and water, air blast apparatus, vertical revoluble conductor extending centrally into tank, hollow arms fixed to and radiating from bottom of conductor and having perforations whereby jets of air are discharged over and through material within tank.

MACHINE FOR GRADING SAND.—No. 800,480; C. W. Palmer, Philadelphia, Pa.



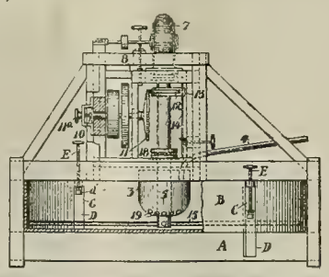
Combination of series of containers each having conduit for liquid overflowing therefrom, means for conveying material from bottom of each container and discharging into another container, receptacle for finished product, conduit connecting overflow conduits with receptacle, and another conduit connecting lower portion of last container of series with receptacle, with adjustable means for directing material from overflow conduit of any container into conduit to receptacle.

SPLASH PLATE FOR STAMP MILLS.—No. 800,398; G. C. Richards, Oakland, Cal.



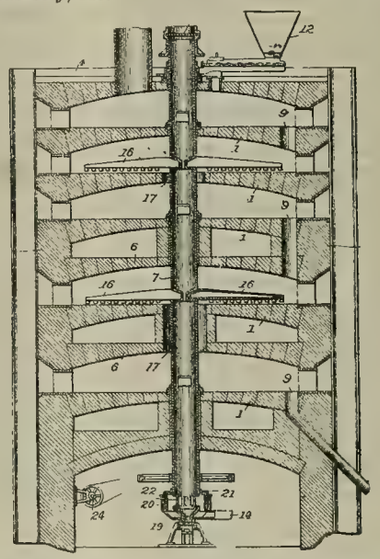
Combination with stamp mortar having screened opening, of splash plate exterior to opening and having inner face presented toward opening and amalgamed and provided with means on face to retard flow of water and sand thereover.

AMALGAMATOR.—No. 800,378; H. L. Lightner, San Francisco, Cal.



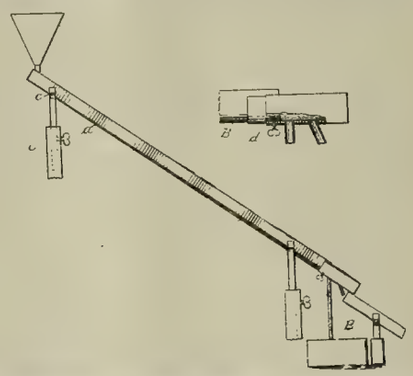
Amalgamator comprising concaved pan having surface coated or charged with mercury, raised concaved center within pan, receiver for water and pulp suspended above pan center and having discharge openings around bottom, air blast apparatus, air pipe extending vertically therefrom through bottom of pulp receiver having perforations in bottom discharging into convexity of raised center, radial arms extending outwardly from tube below receiver and in proximity with concaved bottom, arms having air discharge jet openings in lower part, mechanism by which arms are revolved and rate of speed changed, frame upon which apparatus is carried and means by which frame may be raised or depressed with relation to pan.

ROASTING FURNACE.—No. 800,588; A. R. Meyer, Kansas City, Mo.



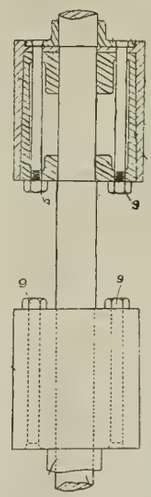
Furnace having side and end walls of masonry and external buttresses, at opposite sides connected by cross beams, with arches 1 extending from end to end and plurality of hearths above each arch, other arches 6 arranged below hearth arches to form intermediate flues, flues connected in series, and plurality of shafts and rabbles carried thereby to sweep over different hearths.

CONCENTRATOR. — No. 800,293; S. L. Hague, Salt Lake City, Utah.



In concentrator having inclined spout with lateral curvatures and converging sides, bottom of spout having downward, transverse curvature and channel along bottom, which is nearer outer than inner side of spout in lateral curvatures.

PROTECTOR FOR THE ROLLERS OF DREDGE LADDERS, ETC.—No. 800,276; R. R. Douglas, Dunedin, New Zealand.



Protector for rollers of dredge ladders, elevators and like, consisting of combination with tapered roller of correspondingly tapered liner provided with circular flange at one end and means for securing flange to roller.

MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

A report on the stone industry in 1904 by the United States Geological Survey states that the total value of stone reported was $74,200,361, a gain of $1,254,453 over the value in 1903, when it amounted to $72,945,908. Granite, marble and limestone increased in value, while slate and sandstone decreased. Granite showed the largest increase. In 1904 its total value, including that of trap rock, was $19,992,983; in 1903 it was $18,436,087, a gain of $1,556,896 for 1904. The granite production increased from $15,603,793 in 1903 to $17,169,437 in 1904, a gain of $1,565,644; and the trap rock from $2,732,294 in 1903 to $2,823,546 in 1904, a gain of $91,252. Sandstone, including bluestone, decreased in value from $11,262,259 in 1903 to $10,295,933 in 1904, a loss of $966,326. The value of bluestone included in the sandstone was $1,779,457 in 1903, and $1,791,729 in 1904, an increase of $12,272. The sandstone figures decreased from $9,482,802 in 1903 to $8,504,204 in 1904, a loss of $978,598. The value of marble increased from $5,362,686 in 1903 to $6,297,835 in 1904, a gain of $935,149. The slate output was valued at $6,256,885 in 1903, and at $5,617,195 in 1904, a loss of $639,690. The limestone output remained nearly the same, being valued at $31,627,991 in 1903, and $31,996,415 in 1904, a gain of $368,424 in 1904.

ARIZONA.

Cochise County.

At the Gold Nugget mine a new shaft is being sunk on the vein and the management intends sinking another one. Sufficient ore is being taken out to keep the mill going. The Gold Nugget is managed by J. G. Pritchard of Bisbee and is in the Bowie mountains, south of Bowie station.——At the Copper Queen mine at Bisbee the new change houses are completed. A new cable has been supplied for the hoist at the Holbrook shaft. It is expected the Holbrook shaft will supply the greatest amount of ore for the reduction plant at Douglas. The Oliver shaft has been thoroughly equipped and is ready for hoisting. At the shaft of the Junction Co. there is a great deal of exploration work is going on under unusual difficulties. A compartment shaft is being raised from the 90-foot level to the surface, and it is hoped it will be finished this month. It will add to the ventilation of the mine, which is now hot, and work can be carried on only in short relays. In the Shattuck-Arizona shaft drifting is going on in the 700 and 800-foot levels. In the latter there are indications that it is approaching the ore body recently passed through by the drift on the 700-foot level. Work in the latter continues with the expectation of finding another ore body beyond the lime formation it is now in. The 8x21-foot shaft on the Denn-Arizona is down over 500 feet and it is the purpose of the management to go at least 400 feet farther without stopping. This shaft was started five months ago. ——A. D. Brewster and others, owning the Randolph mine at Tombstone, have resumed work. A whim will be used at first and until greater depth is attained, when a gasoline motor hoist will be put in.

J. A. Collier of the Vermont & Arizona Copper Co. is crosscutting the ledges that run across the property. The property is 4 miles from Gleason, in the Dragoons.

Rebuilding the Girard mill for the Consolidated Company at Tombstone is progressing rapidly. The grading for the additional twenty stamps has been finished, as has most of the grading for the cyanide tanks; the concrete foundation has been completed.

Gila County.

J. W. Bordman is putting up a custom stamp mill 4 miles west of Payson. Some of the high-grade ore of the district is being shipped to Globe.

The Arizona & Eastern Con. M. Co. has given A. A. Patterson a contract for the development of copper claims on Mineral creek, near Globe.——The output of the Old Dominion smelter for September was 1255 tons, or 2,510,000 pounds, of blister copper, which is a gain over the two previous months. Three furnaces are in blast and the concentrator running day and night. About 5000 tons of Bisbee sulphides have been accumulated and shipments will continue until a stock pile of 20,000 to 25,000 tons has been accumulated. The company also has on hand 7000 tons of coke and a large quantity of fuel oil.

Graham County.

(Special Correspondence).—At the Copper Creek mines, in the Bunker Hill district, Galurio mountains, the company has put in a hoist suitable for sinking 1000 feet, and air compressor and air drills. The machinery is in operation and shipping has been resumed. The main shaft has been enlarged and straightened and timbering put in. A level has been opened at 120 feet, and drifts are in sulphides in both directions from main shaft. The main shaft is 180 feet deep, and the second level will be opened in the sulphide body at 200 feet. The ores are cuprite and chalcocite, with small quantities of malachite and chrysocolla, and occur as fissure veins in rhyolite and as contact veins between rhyolite and porphyry. F. J. Sibley, at First National Bank building, Chicago, Ill., is secretary.

Clifton, Oct. 9.

Maricopa County.

J. Osborn has resumed development work on the Ben Hur mine, near Cave Creek.

Yavapai County.

Diamond drill prospecting is being done at the Verde Chief mine in Black canyon, 9 miles south of Jerome, under the direction of D. N. Bartholdi. —— The shaft of the Golden Idol, near Cherry, is down over 100 feet. The mine is being worked with three shifts.——The Arizona Gold Lode has completed the grading for a 10-stamp mill and cyanide plant at Cherry. —— The Poland mill at Poland has been started, and it is reported that thirty more stamps will be added to it, making fifty stamps in all. The Poland mine had a 3000-foot tunnel and other development before the completion of the Poland tunnel, which cut the main Poland ledge 500 feet from the mouth of the tunnel and at a depth of 300 feet. Drifting on this ledge from the tunnel will give a depth of 800 feet. The Poland tunnel cut a number of other ledges which can be drifted on and the ore cheaply handled and transported to the mill.

W. A. Dearing has charge of work on the claims of the Thumb Butte M. Co., near Prescott.——The claims of the Knickerbocker M. Co. in the Thumb Butte district, west of Prescott, are being developed under the direction of G. U. Young.

The character and amount of assessment work being done near Walnut Grove, in the Bradshaw district, seems to indicate that the great dam washed out by the floods of 1890 is to be rebuilt. The flood took with it $600,000 worth of property, besides causing the death of 100 people. Originally the dam was built as a hydraulic mining proposition. The storage or the upper dam was located at the lower end of Walnut Grove, 35 miles from Prescott. It measured 400 feet from end to end and 12 feet wide on the surface, and at the stream base was 125 feet in thickness. It had a height of 112 feet. At least $5000 a year has been expended for the past fifteen years, in complying with the law governing mining expenditures, as the ground held by the company comprises fifty locations. All the assessment work has been directed toward the rebuilding of the dam. The bedrock foundation has been completed on both sides of the river, and, in the performance of this year's work, it is the purpose to continue the laying of the foundation to greater elevation on both sides of the river.

CALIFORNIA.

Amador County.

Superintendent Webb Smith says that the Kennedy east shaft, near Jackson, has reached a depth of 2945 feet, and that further sinking was discontinued on September 30th. A new station will be opened at the 2850 level, and the work of cutting out for the water tanks, the station levels and chutes is now in progress.——The Keystone mill at Amador City is running to full capacity with sixty stamps dropping and one of the Griffin mills is running.——A. M. Hambric has started the new canvas plant at the Fremont mine, near Amador City.——G. Hambric and J. Glavich are putting up a canvas plant below the Keystone mill at Amador City, to handle the concentrates from that mill.

Butte County.

The Amoskeag mine, near Oroville, is to be pumped out preparatory to being opened up by E. Moore & Co.

Del Norte County.

(Special Correspondence).—Prospecting in the interest of foreign capital continues along the south bank of Klamath river for several miles above Requa. The drill work is to be pushed. The operators have a long term option on many miles of bench and bar deposit. Drills and pumps heretofore in use will be duplicated by those of greater power. It is expected that the lower Klamath river district will be a lively one. On high bars rich gravel has been lifted from a depth of 30 feet, and the showing seems to be satisfactory so far.

Crescent City, Oct. 9.

Humboldt County.

(Special Correspondence).—The Humboldt quartz claim and Humboldt extension quartz claim, Red Cap district, have been located by G. and B. H. Wilder. Many locations have been made in this and Orleans district of late. Sixty placer, quartz and water locations have been made along the Klamath and its tributaries, between Orleans Bar and Klamath Bluffs, since June 1. A new quartz mill has been put in at Orleans district, prospects are being developed, and the outlook for renewed mining effort is good in this isolated region. The same awakening is noticeable along the Trinity river from Willow Creek to the Hoopa reservation.

Orleans, Oct. 10.

Kern County.

(Special Correspondence).—The California Mines Co. has bonded the Baltic mine, ½ mile from Randsburg, and is sinking a 200-foot shaft and building a 60-ton cyanide plant. E. R. Abadie, Jr., is superintendent.——C. A. Burshaw contemplates opening up the Phœnix mine in Johannesburg.

Randsburg, Oct. 10.

(Special Correspondence).—The Exposed Treasure M. Co., operating at Mojave, has decided to cease milling operations for a few months, and will deepen their shaft another 1000 feet. High grade ore, unsuitable for treatment in a free-milling gold mill, has been found below water level. The quantity of water has proven very large, and a large pump will be put in. After further development a new plant, suitable for treating the unoxidized ores, will be put up. C. De Kalb has been retained as consulting engineer.

Mojave, Oct. 11.

Mariposa County.

(Special Correspondence).—The Tennessee & California G. M. Co., near Indian Gulch, have shut down their mine and 10-stamp mill, discharging all employes. The company may be reorganized.——The Grimshaw mine, 6 miles from Indian Gulch, is being unwatered preparatory to opening it up.

Indian Gulch, Oct. 12.

Nevada County.

(Special Correspondence).—The Ethel mine, on Canyon creek, is showing good values as the drift progresses. The new 5-stamp mill is making big cleanups and a 10-stamp mill is planned for next year by Superintendent A. Maltman. The mine has been opened by 1700 feet of tunnels and has already 400 feet of backs. This is believed to be a continuation of the Gray Eagle lead.

Graniteville, Oct. 10.

Sierra County.

(Special Correspondence). — A large cleanup is reported, after running twenty stamps for ten days, at the Mountain mine, near Sierra City. Last year work was resumed on this property after an idleness of several years; the result was the discovery of a parallel vein 150 feet in the hanging wall from the veins previously worked.——Work has been resumed on the Alice and Pappoose quartz claims in Jim Crow canyon, 3½ miles southeast of Downieville. They are repairing the ditch and flume and when that is completed the cannon ball mill will be started.——The new tunnel started recently on the Yuba location of the Sovereign G. M. Co. property is said to show up good values. This property is 3½ miles northwest of Sierra City. G. B. Morse has charge of work at the mine.

Sierra City, Oct 10.

(Special Correspondence).—At Forest City the South Fork Co. have their flume completed and will commence washing gravel in two weeks.——The Maple Grove Co. of Forest City intend to start work on their claims. It is expected that they will strike the continuation of the South Fork channel.——The Forest City M. Co. have a large crew doing development work.——The Lightner, at Alleghany, continues its production of specimen ore. ——T. F. Baker of Honolulu and F. C. Le Blond of San Francisco recently inspected their mine, the Hilo, at Chaparral Hill, which is producing pay gravel.——Wm. Brady of San Francisco has put on a crew to run a tunnel in to gravel on the Irwin ground, adjoining the Hilo.

Forest City, Oct. 10.

(Special Correspondence). — Peckwith & Spaulding have struck the White Bear channel in their ground at West Point. It prospects well.——The Telegraph mine, near Downieville, is putting in an electric plant in Goodyear creek to furnish power to run their mill and hoist. ——The Sierra Buttes Co. have their new cyanide plant running, and will start the 40-stamp mill as soon as their tramway is completed.——The Oaklick Co. are sinking a winze in their lower tunnel, in Jim Crow canyon, near Downieville.

Downieville, Oct. 11.

Siskiyou County.

It is reported from Etna Mills that Geo. V. Gray & Co. have bought the Lanky Bob mine, in the Salmon river district, from George Skillen. The new company will put in a 2-stamp mill at once and commence development work.

Trinity County.

(Special Correspondence).—At Denny, near the headwaters of New river, the Hunter mine, owned by F. J. Ladd, has been acquired by J. P. Hennessy and R. Hicks. The Hard Tack and Cape Nome quartz mines, in the same district, which yielded satisfactorily while operations continued, are awaiting a resumption of development work. The pay streak in all these ledges are small but rich. The purchasers of the Hunter have a 3-stamp mill.——Operations at the Quimby mine, on the lower river, are suspended because of shortage of water. ——Placer miners along 30 miles of New river are hurrying preparations for the winter work.

Denny, Oct. 11.

COLORADO.

(Special Correspondence).—Considerable discussion has taken place recently over the establishment of a National park on the White River forest reserve, on the western slope of the Rocky mountains in Colorado. The reserve mentioned above is located in the counties of Routt, Rio Blanco, Eagle and Garfield. A petition opposing the project is being circulated among the residents of the counties and will be presented to Congress or President Roosevelt. It is claimed in the petition that a park at the point mentioned will be of no benefit to the State or to residents of the district, but will in fact be a detriment.——It is understood that all bids for the completion of the Gunnison tunnel, near Montrose, in the Uncompahgre valley, have been rejected and that the Government will continue the work to completion. The parties who had the contract for the tunnel were obliged to discontinue work, on account of not being able to come out even on the price agreed upon. It was stated at the time that the bondsmen would be held for the completion of the tunnel, and that the Government would not be the loser by having to do the work itself. ——Good roads for Colorado is still taking the attention of parties who are interested in the movement. A project is on foot to build a pike from Trinidad in the southern part of the State to Greeley in the northern end of the commonwealth, touching Pueblo, Colorado Springs and Denver en route. Another one is to begin at Pueblo and end at Grand Junction, near the Utah line. Convict labor is being talked of for doing the work. This part of the programme will undoubtedly be fought by the labor unions.

Denver, Oct. 9.

Boulder County.

(Special Correspondence).—The Jenny Creek, operating at Frantz, has recently put in a 30 H. P. hoisting engine and is developing its property. Sinking is proceeding on the Snow Ball vein. A crosscut is being driven to connect with the Tootsey and Argo veins.

Frantz, Oct. 9.

(Special Correspondence).—The Progressive M. Co. is operating the Mark Hanna mine at Sunshine and is putting in a 25 H. P. hoist and boiler, and expects to have everything ready for development work some time during the month. The shaft on the property is down 70 feet, but will be continued to the 500-foot level.

Sunshine, Oct. 9.

The St. Louis mill has been closed down by Manager Harabel, owing to a failure to provide a settling reservoir for the tailings.——A recent cleanup from the vats of the Cash mill at Magnolia indicates a saving of over 90%.——New machinery has been put in in the Eagle Rock mill and it is now running on wolframite.

The tungsten properties of the Boulder County Farm, at Nederland, under the management of C. F. Lake of Boulder, has been closed down. The mill having but ten stamps and not being fitted for the best saving of the tungsten concentrate, it was deemed best to put in another plant before working tungsten ore. It is said that Manager Lake will build his mill at Nederland on the site of the old Boulder county mill, as Middle Boul-

der creek is a much better water right than the gulch stream, where the present mill stands. The mill now working will continue to operate the gold and silver ore for which it was originally built. Nederland is 18 miles north of Boulder and 4 miles from Rollinsville, on the Moffat road.

Chaffee County.

Work is to be resumed at the Mary Murphy at St. Elmo.

Clear Creek County.

The Red Mountain & Mad Creek M. Co. has been formed at Empire for $2,000,000. The properties are 12 miles west of Empire, in the Dailey district. J. D. Williamson is president.——A. N. Shepard of Denver has commenced work on his claims on Red Elephant mountain, near Empire.

The Centurion G. M. Co. and the Banner Con. Mines Co. of Idaho Springs have entered into an agreement whereby the latter will continue the Rockford tunnel 800 feet, to the intersection with the Little Champion vein. The Centurion management has suspended operations below the tunnel level, and will continue to operate ore bodies above.

The crosscut tunnel being driven by the Leavenworth Mountain M. Co. near Georgetown is in over 180 feet. Manager J. K. Brown is directing the work. The Leavenworth Mountain M. Co. controls fifty-four claims and six millsites on Payne's peak, and every lode may eventually be cut by the crosscut tunnel.——The upraise from the Ashby tunnel level to the old and rich workings of the Dunkirk vein, near Georgetown, has been finished. It will result in proper ventilation for the underground workings, and the work of development being pushed by the Dunkirk M. & L. Co. can be carried on without interruption. E. F. Kendall, manager of the Pay Rock mines, supplied the compressed air, which enabled the leasing company, of which J. H. Crandall is general manager, to finish the work.——A. M. Hill is operating the Julian claims near Georgetown. The Julian lode was recently cut by the crosscut tunnel.——J. O'Connell of Silver Plume has men cleaning out the old crosscut tunnel on the Bertha claims, located on Kelso mountain, near Georgetown.

The Lorella M., M. & T. Co. is working in the East Argentine district, near Georgetown. The Sandberg vein was cut 140 feet from the portal of the tunnel and drifts are being run east and west. A shaft sunk on the Silver Edge vein to a depth of 15 feet resulted in 20 inches of high-grade ore being uncovered. The lode will be cut by a tunnel in another 100 feet. Manager Sandberg has ordered compressor, boiler, engine and water-Leyner drills.——Machinery for the Vidler tunnel power plant has been delivered.——The St. Paul M. Co., operating in East Argentine on Green Lake mountain, is driving the crosscut forward at the rate of 5 feet per day. Manager Mont Tong is employing ten miners.——After driving 60 feet through vein matter the hanging wall of the Domino lode has not as yet been penetrated. H. Cochran is superintendent. The crosscut tunnel is in 320 feet. This property is on Payne's peak, opposite the Sidney tunnel, operated by the East Argentine M. Co. Power drills will be put in and the power secured by running a pipe line from the East Argentine.——The Mazeppa mine on Democrat mountain, near Georgetown, is to be developed by D. W. Shepard. The tunnel is in 700 feet. It is probable that arrangements will be made with the Anglo-Saxon mill for treating as soon as the new mill is put into commission.——Work has been started this week on the Aspen-Promise claims, on Leavenworth mountain, near Georgetown. E. J. Butts of Georgetown, president and general manager of the company, states that he has enough money for continued operation for at least three years to come.

Eagle County.

The Lion's Head M. & M. Co., at Minturn, has suspended temporarily while arrangements are being made for further development. The shaft is down 100 feet, is in the gray lime and will be sent down to the carboniferous, where ore is expected.——On the Lucy, at Fulford, considerable copper is coming in.——Superintendent M. McHale of the Holy Cross M. & M. Co., 16 miles from Red Cliff, is getting the machinery in place on the Bailey properties, and will drive the tunnel ahead soon. This tunnel runs 2000 feet on the vein and is expected to cut the Grand Trunk vein at the 2350-foot point. Air drills are used and the tunnel will be driven with three shifts all winter.

Fremont County.

(Special Correspondence).—Chicago and local parties are making arrangements to build a plant either at Florence or at Canyon City for the treatment of low-grade Cripple Creek ores. The ores they expect to handle will be ores that the present mills in this vicinity do not treat at a profit.

Florence, Oct. 8.

A defective electrical generator started a fire at the Fremont coal mine at Florence, Colo., Oct. 6. All the buildings, including the shaft house, were destroyed. Fifty miners were working in the mine at the time the fire was started, and ten of them were rescued without difficulty. By good fortune the air compressor was not damaged by the flames, and the work of saving the other men was made possible. By the prompt work of their companions they were rescued alive through the air shaft. The men were in the main working shaft when the fire started and were unable to get to the surface by reason of the flames having destroyed the main shaft. Superintendent McAllister, realizing their danger, signaled them to hasten to the air shaft and that ropes would be let down to rescue them. They acted at once, and while all the available men in the camp were fighting the flames, which were extinguished several hours later, Superintendent McAllister and twenty men were hoisting the miners from the air shaft one at a time.

Gilpin County.

A gasoline hoist is being put on the Hampton mine, Russell gulch.——R. G. Griffith & Co., of Russell gulch, are leasing on the Saratoga No. 3, west of the main shaft, in the Russell district. They have a good plant of machinery and are stoping west from the shaft at a depth of 300 feet.——The Dump lode on Gregory mountain, operated by Phillips & Co. of Central City, is ready to start shipping. The shaft is 350 feet deep and levels have been driven east and west.——Frank Poole, of the West Notaway mine, near Central City, has ten men working on the lease system. The ore is of a smelting character and does not do well in the stamp mills, as it is too refractory. The main shaft is down 500 feet, but most of the work is being done between the 200 and 400-foot levels.——The East Notaway, on which the shaft house was destroyed by an explosion, is again running. Tom Martin is looking after operations and running the hoist.

Charles Horning of Nevadaville has leased the Smuggler claim in South Moon gulch from Hawn, Stephenson & Co. of Rollinsville. The property is developed with shaft and a tunnel in 300 feet. Horning has made plans for a ten slow drop stamp mill of the amalgamation and concentration pattern. —— Grading is under way for the new 10-stamp mill of the Penobscot M. & M. Co. in Gambell gulch, near Central City, near the mouth of its main tunnel, which is in 1900 feet on the vein. The tunnel workings are 400 feet below the bottom of the Penobscot shaft and an upraise is to be made. They intend to drive their main tunnel 8000 feet to Tip Top mountain. —— Sinking at the Clay County mine in Lake gulch, near Central City, has given a depth of 640 feet. —— Eilmann & Co. have commenced work in the main shaft of the Susan Mary mine near Lake gulch.

Gunnison County.

A new air compressor has been put in at the North Pole mine, near Crested Butte, by Manager W. T. Deaner. The company have purchased the Hard Cash ore that was not treated by the mill at Gothic and will ship the same to the smelter at Grand Junction.——The Ruby Peak M. & M. Co. has resumed work near Irwin under the direction of Superintendent M. Pennington.

At the Napoleon mine, near Pitkin, the ore body has been drifted on for 15 feet, and assays show the ore to run from 40% to 48% zinc. The main incline will be sunk 75 feet to catch this ore body.

Hinsdale County.

The Hanna mill at Capitol City may be completed by Nov. 1. Three sets of jigs are being put in.——The Pittsburg Metals M. & M. Co. will put in an engine, dynamo, 3-drill compressor and boiler. Bunk and boarding houses will be built and preparations made for continuing operations throughout the winter. Underground drifting is now in progress on the Wyoming vein, and several carloads of the material will be sent to Durango and Salida smelters for test runs.

Lake County.

The connections with the Yak tunnel and a drift in the Tuscan at the bottom of the drift have been made and the shaft of the Tuscan is now going down and will be sunk another lift of 450 feet, making it 950 feet when completed. All of the water struck in sinking will be lifted to the 550-foot level, and from there diverted to the upraise and then through the tunnel. This will reduce the expense of sinking considerably. It will probably be the first of the year before sinking is completed.

The owners of Peoria Boy on Breece hill, near Leadville, are drifting from the tunnel level to the shaft, a distance of 400 feet.

South of Yankee hill, near Leadville, the large tanks for the tailings of the Wolftone mine are being housed. ——The Bohn shaft, near the Penrose mine, Leadville, has been started, with J. W. Newell as manager. The mine has been idle for some time.——Lead and zinc ore has been struck on the Ponsardin shaft on Yankee hill, which was recently started up again after an idleness of seven years.——The El Paso mine on Fryer hill, Leadville, is shipping two cars of ore a day. The pump works from a depth of 550 feet and has a capacity of 560 gallons.——A. V. Bohn is sinking a shaft on his Mammoth placer claim. A depth of 450 feet has been reached. An air compressor has been put in the mine.

More work is being carried on at present in the downtown section of Leadville than for several years. The last property to be started after several months of idleness is the A. V. shaft. The drifts are being cleaned out and put in good working order, and when completed breaking ore will commence. A switch will be laid to the ore bins to facilitate the shipping of ore. When this shaft was first opened considerable high-grade chloride ore was shipped, and the present lessee, T. S. Schlessinger, expects to open another body of it in the ground to the south, which has never been prospected. The south drift of the Cloud City is being driven to connect with the bottom of the Home Extension shaft. The Coronado is producing from 250 to 300 tons daily of siliceous lead ore and from the Northern, Poverty Flats, 100 tons daily of a good grade of iron is going to the smelters.

Montezuma County.

(Special Correspondence).—The center of activity in quartz mining in this county is the Old Kentucky, on the East Mancos, 10 miles from the town of Mancos. A good deal of prospecting and assessment work is being done, but the only real mining is in the O. K., where air drills have been steadily at work since spring and now have the tunnel in 450 feet. The vein remains strong, from 1 to 7 feet wide, and carries good milling values all the way, with a good streak of shipping grade. All the ore is being left in the dump, as the company intends to put in a mill next spring.——A good strike was recently made on the East Mancos, 3 miles above the O. K. The vein is a true fissure, 1 to 3 feet wide so far as opened, all shipping ore, much of it assaying over $600 in gold.—— Placer mining in this section has received an impulse this summer which bids fair to put it far ahead of quartz mining within a short time. Half a dozen different concerns have been at work on the San Juan, southwest of Mancos, and the bars for 100 miles are being systematically prospected. One small outfit has been at work for some time with a hydraulic plant and has obtained good results. Another company recently acquired an option on a large area and has shipped in a Keystone driller, with which it intends to put in the entire winter prospecting. The manager of another company has gone East to order a plant which will handle 1000 yards per day. It will consist of a floating mill, power shovel, and tramway, probably operated by electricity. The high bars are said to average over $2 per yard.

Mancos, Oct. 9.

San Juan County.

Among the new mills under construction, all slated for completion on or before the last of December, are the Gold Prince 500 tons, Old Hundred 300, Grand Mogul 150, Green Mountain 200, Hamlet 75, Arkansas Company 100, Sound Democrat 100, making from these sources 1425 tons daily of crude oil reduced to concentrates. Adding to these the product of the Gold King 400 tons, Silver Lake 500, Iowa-Tiger 250, Silver Ledge 150 and the Sunnyside (which is preparing to double its capacity and has purchased an electric separator for zinc saving, thereby enabling its owner to handle 300 tons a day) gives a total of 3025 tons of crude material daily that will be raised and treated at the several establishments named. This should yield over 600 tons of concentrates on the estimated average of five tons to one.——The lower terminal station of the Iowa M. Co.'s tramway line from the mill to the Silverton & Northern railroad was burned recently. The terminal building was a two-story frame structure, from which concentrates from the mill were loaded for shipment. The loss will amount to about $4000. The Iowa mine and mill have been idle for the last three years. It is not likely the terminal will be rebuilt or the tramway repaired before next year.

The Champion 1500-foot aerial tramway, on Sultan mountain, south of Silverton, has been completed. Heretofore the mineral has been transported down to the railroad by burro pack train. Work on the Champion will continue all winter, and the output of the mine will be steadily increased.——A big strike is said to have been made on the Moses claims, on the eastern slope of Bear mountain, owned and operated by Mrs. M. A. Garrett of Silverton. The strike was made on one of the crosscut tunnels, 175 feet from the portals and at a depth of 200 feet.

San Miguel County.

A mill for the treatment of vanadium ores is to be built at Newmire by S. W. Traylor and H. A. Hillman. Considerable vanadium ore has been taken out at this place and it is thought that a mill will stimulate the search for other bodies of vanadium ore.

Summit County.

(Special Correspondence).—The Old Union mill is running continuously with two shifts of twelve hours each, handling over 100 tons and producing 25 tons of concentrates per day.——The Lucky mine on Mineral point is shipping high-grade ore from the main shaft workings and is producing a good grade of milling ore for concentrating at its own mill. The same management has the Carbonate mine on Mount Baldy. —— The Reliance Dredging Co.'s large dredger is working smoothly now that the excavation is large enough for it to move around.——The Summit Banner Placer Co. in a cleanup of its sluice boxes and tables saved $1.03 per cubic yard. The black sand that is being saved in the steel riffles and on the new patent concentrating tables has given assays of 8.39 ounces per ton.——The Washington-Joliet M. & M. Co. are increasing their milling capacity by additional concentrating tables and will resume milling operations soon. —— The Morning Star mine on Mount Baldy, besides having been shipping a high-grade silver-lead ore for some months, has discovered a good, rich ledge, which is producing high-grade ore. —— The Sallie Barber mine is making considerable shipments of zinc ore to Kansas City.——The Abundance mine is being opened up at the lowest levels with good results. The shaft is being continued down.——The Jessie mine and mill are being worked continually by the leasing company and good returns from bullion and concentrates are being obtained.——It is reported that there is to be a consolidation of the Gold Pan M. Co. and the North American M. Co., to work both properties.

Breckenridge, Oct. 9.

Teller County.

Good shipping ore is being taken from the Bill Nye claim of the Copper Mountain Co. by the Metallic M. & L. Co. of Cripple Creek, under the superintendence of R. Blanchfield.——A good strike is reported from the C. F. Springer lease on the Oro, on Ironclad hill.—— Preparations are being made by A. Holman and associates to work the Christmas mine of Bull hill on a larger scale. They have bought a 10-drill compressor and 125 H. P. boiler from John Sharpe, lessee of the Colorado Boss, and will soon have it in position and operation. With this plant it is proposed to increase the depth of the shaft, the bottom of which is at the 300-foot point, and at 1000 feet to crosscut for some of the bodies known to enter from neighboring mines. These shoots will also be sought on existing levels.——E. S. Johnson of Colorado Springs, operating on the Blue Bird, on Bull hill, near Cripple Creek, has put in a 250 H. P. Corliss hoist. The shaft has been fixed to accommodate the cage, replacing the bucket hitherto used. Drifting to break into the Portland workings to secure ventilation has been started.

The main shaft of the Golden Cycle mine at Cripple Creek, that is now 1000 feet in depth, is to be deepened an additional 200 feet immediately, and when that is completed will be extended out and the ore cut again. The Golden Cycle Co. has decided to build a cyanide mill of 200 tons capacity, which will cost $200,000 when completed. The building will be so constructed that, if necessary, additional tanks can be put in which will bring the capacity up to 500 tons daily. The management has not decided if it will erect the mill on its property near Goldfield, or whether it will be constructed on a millsite which the company owns near Colorado City.

IDAHO.

Blaine County.

Superintendent Ruthrauff announces that the Dollarhide mill, 20 miles west of Ketchum, is enclosed and will be ready for operation by October 1. It will be run only a short time, however, as it is the intention to have the ores thoroughly tested before installing any extensive concentrating system. The ore is carrying 25% to 35% zinc, which will be separated and sold as zinc concen-

trates. Considerable ore is accumulating and over 400 tons are now waiting to be moved to the mill.

Boise County.

Manager W. T. Nassaur of the Whitman Co. of Pearl has opened the fourth shoot of the Leviathan vein after driving the adit level 622 feet.— The new cyanide plant at the Lincoln mine at Pearl has been finished and is running.

Idaho County.

Seattle lessees have resumed work on the Comstock mine near Dixie.——A 100-ton mill is being put in at the Bandette mine, near Oro Grande. Oro Grande is 70 miles from Stites, the nearest railway point. —— The Champion 10-stamp mill, near Elk City, is running. —— It is reported that a new mill is to be put in at the Oregon mine, near Elk City. —— The Sunnyside mine, near Roosevelt, is being worked with forty-six men under the direction of R. W. Purdom. Cyanide tests on the ore have been satisfactory and a plant may be put in.

Kootenai County.

The Golden Reward mill on upper Alder gulch, 1 mile north of Cœur d'Alene, is making good progress and Superintendent Kepp is pushing the work.

The Tyson Con. M. & M. Co., at Tyson camp, 20 miles from St. Marie, on the St. Joe river, is putting in an 8-mile pipe line for box and hydraulic sluicing of the gravel. The quartz leads are also being exploited. J. S. Haviland of St. Marie is general manager.

Lemhi County.

(Special Correspondence).—After a number of years of inactivity, the Texas mining district is again on the boom. Present operations are at Gilmore and Spring mountain, at the head of the Lemhi river, 80 miles from Dubois, Idaho, and 65 miles from Redrock, Montana, the nearest railroad points. Salmon City lies 70 miles down the valley, at the mouth of the Lemhi river, which flows into the Salmon river. The Gilmore M. Co. are down 275 feet. New machinery is being put in to sink to the 500-foot level, as well as an increase in their concentration plant to fifty tons capacity. At present the ore is hand sorted into first and second class, the first class going to bins for immediate weighing and shipping, and the second class is dumped on floors, screened and concentrated with jigs, the coarse or large pieces being resorted and emptied into the bins for shipment. Crushers are to be put in. The cost of transportation, including smelter charges, amount to $30. The ores are first hauled by wagon to Dubois, Idaho, 80 miles, and from there to Pittsburg, Pa., by rail. Freighters haul over a ton to the animal, it being a water grade and good roads. They receive $10 per ton for ore delivered in Dubois. The output of the mine is now about a car per day. This vein lies between porphyry and limestone, and varies in width, in some places being 20 feet wide. The shaft is equipped with a gasoline hoist, and concentrators are operated by steam power. The mines of Spring mountain lie 10 miles south of Gilmore. These properties are being worked on a large scale by Salt Lake people. No ore has been shipped this season, the supposition being that a smelter will be put in when sufficient ore has been blocked out to justify it. Many new strikes are reported and a number of sales made, notably a property 25 miles southeast of Gilmore, on Birch creek, to be operated by an English company. The Texas mining district promises to be one of Idaho's best silver-lead camps.

Gilmore, Oct. 7.

The 30-stamp mill and cyanide plant at the Kittie Burton mine, at Indian creek, north of Salmon City, has been destroyed by fire. The mill cost the company about $45,000 and was insured for about two-thirds of that amount.

Shoshone County.

The German-American M. Co., developing the Phœnix property, near Osburn, has the main tunnel in 975 feet, with a depth of nearly 900 feet below the surface outcrop. It is stated by the management that for a distance of 150 feet the average daily progress made with the 18-pound Hardsoeg hand drill was 7½ feet, the ground being broken 7x5 feet. It is the intention to continue the main drift, as indicated, and crosscut to the several parallel leads on the property. W. P. Belding is superintendent.

The Gold Ridge M. Co. intend sinking 100 feet deeper on their claims in the St. Joe mining district, 18 miles south of Wardner. D. Davis is manager.

MISSOURI.

Jasper County.

During September the lowest price paid for top grade zinc was $40 a ton during the first week of the month, since which the top price has been above $50, and the month closed with the price at $55. The output of zinc for the nine months just ended has been 376,456,780 pounds, which was sold for $8,424,385. During the corresponding period of 1904 the output was 386,719,490 pounds, which sold for $6,500,790. These figures show that the 1905 shortage of over 21,000,000 pounds in production, which existed September 1, has been reduced to a little over 10,000,000 pounds during the month. For the first time in 1905 the value of the lead output exceeded that for the corresponding period of 1904, although the output of lead is still below that of last year—the total production being 45,971,340 pounds, which sold for $1,358,540, as against an output of 48,702,560 pounds, which sold for $1,324,450 during the same period of 1904. The total value of both ores during the first nine months has been $9,784,124, which is an increase of $1,958,885 over the total production for the corresponding period of last year.

MONTANA.

Chouteau County.

Whitcomb & Phillips are working the Ruby Gulch properties near Zortman. It is reported that they intend to put up a new mill. They already have a mill and cyanide plant.

Granite County.

In the Red Lion district, near Philipsburg, the Southern Cross litigation which has kept the mine closed down is so far over that work has been resumed by Lucien Eaves. He had gone down 200 feet on the incline, on the new ore body opened up a year ago, when the mine was closed down. Operations at the mine have been resumed by putting men to sink this shaft on the new ore body 100 feet. Shipping ore is to be commenced as soon as the 300-foot level is reached.

Jefferson County.

The Pen Yan and the Blue Bird mines, near Corbin, have been bonded to a Michigan company by Parchen & Keefe. Superintendent McCabe has started work with three shifts.

Powell County.

At the Coloma mines, 1 mile from Coloma, work is under the supervision of H. V. Salisbury. The Comet group comprises fourteen claims and is owned by Philadelphia capitalists, H. J. Seible, Jr., being the president of the company. About 3000 feet of work has been done. The property is being developed by means of an incline shaft, which is down 400 feet. There are two main levels, at 200 and 400 feet. A crosscut is being run from the bottom of the 400-foot level in the direction of the Mammoth mine, of the group at Coloma. It will be required to run this crosscut about 800 feet to reach the lead in the Miner's Dream. Superintendent Salisbury is also starting to sink from the bottom of the incline shaft.

Silver Bow County.

(Special Correspondence).—In September the Butte mines yielded 409,500 tons of ore and 26,970,000 pounds of copper. To each pound of copper there was a bi-product value of 2½ cents. The following table shows the monthly output:

Companies	Tons of Ore.	Pounds Per Ton.	Pounds of Copper.
Boston & Montana	90,000	70	6 300,000
Anaconda	132,000	55	7,260,000
Butte & Boston	18,000	63	1,134,000
Parrot	16,500	68	1,122,000
Washoe	24,000	70	1,680,000
Trenton	18,000	58	1,044,000
North Butte	18,000	140	2,520,000
United Copper	45,000	70	2,700,000
Clark Mines	33,000	70	2,310,000
Miscellaneous	15,000	60	900,000
Totals	409,500		26,970,000

The rich yield of North Butte is due to the fact that only a very high grade of ore is being mined, while the shaft is being retimbered and the ore is hoisted through the shaft of the High Ore mine, one of the Anaconda properties. It will be a month or six weeks before the shaft is completed, and then the output will be increased fully 30%. The general average of the ore of the North Butte group is double the value of any other ore mined at present in the Butte district.——A new company, that will probably be known as the East Butte, is being organized for the purpose of consolidating about ten or twelve producing mines in the southeastern portion of the Butte district. The company will take in all the territory lying between the Pennsylvania mine of the Boston & Montana Co. and the Kane shaft of the Butte & Boston. Within the territory already secured are ten producing shafts, but the claims are all small, with the exception of the Oneida, which is a full mining claim. Among the properties already taken in are the Yankee Boy, with a 250-ton concentrator; the Mary MacLane, Oneida, Dutton, Symon and two others not made public. The shafts are from 53 to 300 feet deep, and ore is being taken from all of them. The ground is surrounded by the Pennsylvania, Glengarry, J. I. C., Kane, Silver Bow Nos. 1, 2 and 3, and Heinze's Belmont. It is predicted that the East Butte will rival the North Butte as a producer. Butte and Boston and New York men are interested in the new company.

Butte, Oct. 9.

NEVADA.

Esmeralda County.

Arthur Winslow of Boston, manager of the Combination Co., is at Goldfield looking after the new addition to the mill and the development of the mine. The details of the mill work are in the hands of F. L. Bosqui. The original mill was built as suggested by him after he had made tests on the ores. The present mill is adapted for the reduction of the oxidized ores, but in the new addition provision will be made for treating the sulphide ores of the lower levels, and Mr. Bosqui expects to make the same high saving of values that he does on the oxidized ores. The concrete work for the batteries and bins is finished, the material for the building is nearly all on the ground and the machinery all ordered. From the stamps the ore will go to a grinding mill, then a Wilfley table, then to four Frue vanners. All the tailings from the Frue vanners are reground in a tube mill and then concentrated, followed by cyaniding. The ores do not amalgamate as well as is generally believed, the saving on the plates being but 35% to 50%; 7% of the values are saved in concentration and the balance by cyanide. When the new addition is finished the mill will treat 80 tons per day. At the mine, a gallows frame for the new 30 H. P. electric hoist is being built at the new working shaft, which is now down to water level—240 feet. A cage will take the place of the bucket. E. A. Collins is superintendent of the mine.——The American M. Co.'s mill and cyanide plant at Goldfield is running under the direction of F. A. Doran.

Operations have been resumed in the main workings of the Goldfield-Portland Co.'s ground and the work of sinking the shaft to the 500-foot point is to be started as soon as the necessary timbers can be landed at the property. John McKane has a lease on the territory and is planning to develop and prove up the ore bodies. D. B. Gillies is in charge.

Eureka County

The Eureka M. & M. Co. are putting in new milling machinery and a compressor at the Bay State mine at Newark, near Eureka. C. M. Perry is president of the company.

Humboldt County.

(Special Correspondence).—H. Bender has bonded three claims, near Jackson creek, for $12,000 to Copley of Kansas City.

Humboldt House, Oct. 10.

Lincoln County.

S. P. Moore, superintendent of the Interstate M. & R. Co., is developing a gold property at Fay. A mill is to be put up.——G. E. Otis of the Cyrus Noble M. Co. of Searchlight states that the company will put up a 10-stamp mill on its properties near Searchlight.

The shaft on the Techaticup mine, at El Dorado canyon, is being driven to the 500 level. At the 400 a crosscut was run to the vein. The mine is under the management of Charles Gracey.

Washoe County.

The Harris mine, near Washoe City, has been sold to Indiana capitalists, who are getting the workings in shape and intend to build a 10-stamp mill near the mine. ——The Smith mine in the same district has been sold to Colorado men, who will open it up. They purchased a millsite of four acres and will build a mill.

NEW MEXICO.

Grant County.

W. E. Hockie has charge of the properties of the North American Co. at Lordsburg. Men are sinking the main shaft on the Cobra Negra under his supervision.——The Morning Star Co. have decided to sink a development shaft on the Atlantic, near Lordsburg, to a depth of 800 feet.——The main shaft of the Cobra Negra, of the North American M. Co., at Lordsburg, has been unwatered and sinking has been resumed.—— Work has been resumed on the Old Commerce at Ash Peak.

Sierra County.

A concentrating plant is to be put on the Virginian, Templar and Keystone, near Kingston. The plant will have a capacity of 100 tons a day. Ore thrown on the dump in 1885 and 1886 is to be treated. J. H. Moffatt is the superintendent and A. W. Harris of Kingston is the principal owner. The property has been leased to a company, of which B. S. Rodey of Albuquerque is the president.

OREGON.

Baker County.

The mill and cyanide plant at the Mayflower mine, near Cornucopia, is nearly completed. Work is being pushed on the aerial tramway.——The 10-stamp mill and concentrators at the Gold Coin mine, 3 miles from Rye Valley, are almost completed.——Manager T. Kennerly has finished surface improvements at the John B. Sipe group, near Bourne, and will continue work through the winter.——The Victor crosscut near Bourne is in 1000 feet. Machine drills are being used in drifting on the No. 2 vein cut by the crosscut.

Douglas County.

The aerial tram connecting the Musick mine and 30-stamp mill, near Bohemia, has been finished. Development has been resumed in the mine.——The Bohemia Mine Owners' Association will hold their annual meeting in November. —— The Vesuvius mill at Bohemia has resumed operations after a shut-down for repairs.

Grant County.

It is reported that the main Gold Bug vein, near Granite, has been cut after running the crosscut tunnel 800 feet. Manager T. S. Van Fleet has sacked some of the ore for shipping.——The new mill building at the Standard cobalt mine, near Comer, has been finished, and the crushing and concentrating machinery is being put in as it arrives.

Jackson County.

The Maid of the Mist property, 4 miles from Applegate, is to be worked by E. M. Wright and brother of Union, Oregon, and C. Hawkins of San Francisco. They are building cabins and intend to put up a mill building soon, as there is said to be enough ore in sight to warrant construction of a small plant.

Josephine County.

A good pay shoot has been opened by the 525-foot tunnel at the Eureka mine, near Selma. A. F. Nelson is manager.——C. B. Kelton has started work on the Calumet main tunnel, near Selma.

Manager O. L. Tutt of the Takilma smelter says that he will have to close the smelter by November, owing to the condition of the roads. The 42-mile haul from Grants Pass becomes impossible when fall rains set in. During the winter the smelter management will rush development.

Malheur County.

A large seam of coal, reported by prospectors to be 20 feet thick, has been located at the mouth of Dry creek, 35 miles southeast of Ontario. The preliminary work done on the discovery indicates that the seam will produce a good grade of ore, and it is the purpose to arrange for thorough prospecting. The discovery is in the same general vicinity as Malheur oil formations, which attracted much attention a few years ago. Miners have been confident of coal in the district, but exploratory work had never been thorough enough to determine where the measures would be found and the wash of the country is too heavy for the prospector to learn much from croppings.

SOUTH DAKOTA.

Lawrence County.

The annual report of the Homestake M. Co. for the year ending June 1, 1905, has recently been issued, and is of more than usual interest. The company has developed the largest body of gold-bearing ore in the world, and though low in grade—less than $4 per ton—so carefully has the business of mining and ore reduction been systematized there, that a substantial profit results from these operations. The company is mining and crushing nearly 1,500,000 tons of ore annually, the daily run being about 4000 tons. There are six shafts from 800 to 1400 feet deep; six mills, containing in the aggregate 1000 stamps (some additions having been made the past year), crush this ore through a 40-mesh screen, much of the pulp being reduced to a fineness of 200 mesh. Two great cyanide plants handle the sands, there being an almost perfect separation of sands and slimes, and a plant is now being installed which will remove a large percentage of water from the slimes, which will render

the latter amenable to cyanidation as readily as the sands. The more important items of mining and milling cost are here mentioned, together with the cost of similar operations during the previous two years for the purpose of comparison, and will prove of interest to miners elsewhere:

Item.	1903.	1904.	1905.
Total production	$4,526,942 04	$4,800,558 48	$5,221,089 30
Tons milled	1,279,075 00	1,299,057 00	1,398,100 00
Average per ton	3 539	3 695	3 734
Dividends paid	819,000 00	655,200 00	819,000 00
Property purchased	5,167 76	210,168 85	1,784 48
Mine labor	1,548,447 07	1,570,740 00	1,671,271 84
Taxes	67,530 59	78,758 10	85,861 46
Water	96,099 44	65,747 48	30,313 78
Interest	31,139 56	.....	16,028 47
Indebtedness	425,784 97	.....	.....

The cost of mining the past year was about $1.14 per ton. The cost of milling, cyaniding, etc., is not given. In former (recent) years the dividends were somewhat larger than during the past three years, being in 1900, $1,175,000, in 1901 and 1902, $1,260,000 each year, but owing to extensive and expensive additions to plant, the dividends have of late been somewhat lower, though higher the last than the previous year. It is anticipated that the dividends of the present and immediately succeeding years will show an increase, as the increase in milling capacity will have a noticeable effect. The contemplated slimes plant, the construction of which is now in the preparatory stage, will form a large item of expense, as will also the water power installation now being made, but the economy of these investments will later become evident. The total dividends paid by the Homestake Co. proper up to and including September, 1905, is $13,896,350. If with is included those paid by the De Smet, Deadwood-Terra, Caledonia, Highland, Golden Star and other subsidiary companies absorbed by the Homestake Co., the total amount would be about $25,000,000 from ore averaging not above $4 per ton. The annual report of the superintendent, I. J. Grier, is characteristically brief and contains the following: "During the twelve months now closing no mishap to the property of especial importance occurred. Developments in various parts of the mine progressed steadily and satisfactorily. The ore at the 1250-foot level has just been reached and is now being crosscutted. The Ellison shaft has been sunk to 1400 feet and the work of opening a level at that depth begun. The B. & M. shaft has attained a depth of 1250 feet, the Golden Prospect 900 feet. The Old Brig and the Golden Gate remain at 800 feet each and the Golden Star at 1100 feet. The plant generally is in fine condition, with ore in sight for a great many years."

Work commenced October 6 for the new slime plant which the Homestake Company is about to build at Deadwood. Men were put to work grading for the ditch through which the iron pipes containing the slimes will be run. A tunnel will also be driven beside cyanide No. 1 through the hill to the north. The pipes will be laid through this tunnel, thus cutting off several hundred rods of distance between the mills and plant. For the past month work has been carried on in Blacktail, fixing foundations and moving buildings in order to obtain a suitable site for the new settling tanks, which will have to be built on that side of the hill. Work for the grading of the plant itself will be begun in Deadwood as soon as the houses on the site can be moved.

Pennington County.

(Special Correspondence).—A spur is being built westerly from Rapid creek, near Nahant, by the Burlington road, toward the Wyoming line, presumably to the coal fields of western Wyoming.

Nahant, Oct. 7.

UTAH.

Beaver County.

The first shipment of ore from the Majestic Co.'s Harrington-Hickory mine, under the Newhouse management, has been made from Milford.——The Hecla, 10 miles east of Milford, is being developed by H. Harris. ——A. C. Washington, president of the Horn Silver mine at Frisco, accompanied by Manager P. T. Farnsworth, visited the mine recently.——Manager J. A. McMullin is having the assessment work done in the O. K. Extension Co.'s properties, near Milford.

Carbon County.

The shaft being sunk at the Overland mine at Sunshine is down 220 feet.

Juab County.

The management of the Mammoth M. Co. contemplate putting in an aerial tramway to convey ore from the mine to the loading station at Robinson, a distance of 1 mile.

Tooele County.

It is reported that Manager Trenam of the Stockton mine at Stockton intends to put in a new hoist and air compressor. The present hoist is taxed to take out ore from the 850-foot development work. The mill has been running with but one shift because of water shortage.

WASHINGTON.

Okanogan County.

The Palmer Mountain T. & P. Co. is putting in a 3000 H. P. power house and a 300-ton milling plant and an air compressor at the mines near Loomis. The first unit, 750 H. P., of the power plant, will be in readiness within a month, when the work of extending the 4400-foot tunnel will be resumed. It is the plan to extend this bore an additional 4700 feet, making a total length of over 9000 feet. J. Boyd is the manager and E. Beidler is the superintendent in charge.

Stevens County.

Silver Queen Mines, Ltd., are working claims in the Kettle river valley, 3 miles south of Kettle Falls. Hoisting and pumping plant will be put in. W. W. Warner is the superintendent and R. K. Green is manager.—— The new smelting plant of the Turk M. & M. Co. in the Cedar Canyon district, near Davenport, is temporarily out of commission. The Silver Seal Co., F. M. Van Horn manager, is producing steadily. The Providence M. Co., S. L. Boyer, manager, has also made a number of profitable shipments. The Deer Trail M. Co. has started work at the Royal. The First Jump M. Co. has taken over the Brooks property between the Silver Seal and First Jump. The Deer Trail Consolidated M. Co. has adjusted its difficulties and will resume work with W. W. Tolman of Spokane as manager. These mines are all tributary to Davenport.

FOREIGN.

CANADA.

BRITISH COLUMBIA.

Boundary District.

(Special Correspondence).—The 40-stamp mill of the Daly Reduction Co. at Hedley is crushing over 3000 tons of Nickel Plate ore per month, with returns of $14 to $15 per ton. They have 250,000 tons blocked out in sight. R. B. Lamb has charge of the mill and M. K. Rodgers is superintendent of the mine.

Hedley, Oct. 7.

East Kootenay District.

The Sullivan mine, at Kimberley, is being prospected with a diamond drill.——The buildings at the upper end of the St. Eugene tramway were recently burned.

The big shaft house at the Lake Shore workings of the St. Eugene mine, near Moyie, was burned to the ground Oct. 6, and the loss will probably reach $30,000. The timbering in the shaft and in the main tunnel was partly burned. This is the second bad fire within ten days that the St. Eugene has had. The buildings will be rebuilt.

West Kootenay District.

(Special Correspondence).—Work has been started on the Silver Dollar mill on Mohawk creek, near Camborne. Water is to be used for power. The pipe, 18 inches in diameter, is of wooden staves, wound with galvanized iron wire and coated with pitch. —— The Mammoth group, above timber line on Goat mountain, near Camborne, is to be worked throughout the winter under the direction of M. McCollom. The ore is galena and gray copper, carrying high values in silver. It is handpicked at the mine and rawhided as soon as the trail is in condition.

Camborne, Oct. 6.

At the Mother Lode, at Poplar creek in the Trout Lake division, 600 feet of tunneling, shafting and upraising has been done. In the No. 1 tunnel the ledge has a width of 35 feet, with an ore shoot that varies in width from 7 to 8 feet. There is 18 inches of ore in the 7 or 8-foot shoot and the remainder is concentrating ore. Work has been started on No. 2 tunnel so as to prove the ledge at depth. This tunnel, when driven for 400 feet, will strike the ledge at a depth of 400 feet. The chief values in the ore are silver and lead, with some gold. It is a concentrating proposition, and ultimately a concentrator will have to be provided.——Chisholm & Simpson are developing the Calumet and Hecla, on Rapid creek, near Poplar. A shaft has been sunk to a depth of 35 feet on the ledge. It is a free gold proposition.——Marquis & Gilbert, the owners of the Gold Park group, which were the first claims staked in the Poplar camp, are closing a deal with a Minneapolis syndicate, which has ample means for development.

MADAGASCAR.

Consul Hunt of Tamatave writes that there are bright prospects of gold being found in very large quantities in Madagascar. He says that the exports of gold in 1903 and 1904 amounted to 4211 and 5423 pounds, respectively. Quite a number of persons are prospecting for gold, but most of them are men who have had little experience in prospecting. Gold dirt has been found that yields $34.70 per metric ton (2200 pounds). Gold-bearing reefs and alluvial deposits have been found in various parts of the island.

MEXICO.

A statement issued by the Mexican Treasury Department, covering the exportation of precious metals by that country in the eleven months from July, 1904, to May, 1905, inclusive, shows an increase of $2,551,020.07 of gold over the corresponding period of 1903-4 and a decrease in silver of $13,478,934.46. The silver decrease was the result of the adoption of the monetary reform, which discontinued the exportation of silver dollars. In the period mentioned (July, 1904, to May, 1905) there were exported:

Mexican gold coins	$85,911 00
Foreign gold coins	39,132 50
Gold in bars	11,307,354 80
Gold in other forms	921,393 49
Total gold exported	$12,353,781 79
Mexican silver coins	$1,892,071 27
Foreign silver coins	76,471 00
Silver in bars	47,385,298 92
Silver in other forms	9,982,433 32
Total silver exported	$59,336,274 51
Copper	$26,237,018 96
Lead	5,112,408 00
Other mineral products	1,049,206 39
Total	$32,398,633 35

The total exportation of gold, silver and other metals shows a decrease of $5,182,748.78 as compared with the corresponding eleven months of 1903-4.

PHILIPPINE ISLANDS.

According to a recent government report in Lepanto, in the copper district of Mancayan, on the Island of Luzon, forty claims, including the Santa Barbara and Sin Nombre pertenencias of the Spanish regime, all now located under the present mining laws, have been secured as an option by agents of a New York syndicate. The old Spanish workings have uncovered large bodies of high-grade copper ore on the Santa Barbara and the Sin Nombre claims. In Batangas Province work has been done in the Loboo Mountains upon a group of claims containing copper carbonate ores, two surface samples of which have assayed respectively 2.71% and 17.1% in copper, with a trace of gold in each.——In Rizal Province placer washing for gold has been carried on by the natives for many years, and this has led American prospectors to the search for the origin of the gold in the hills. No important discoveries have as yet been made, however, other than the discovery of platinum, identified in small quantity in placer sands from Rizal.

Personal.

A. A. BLOW is in New York.

EDWARD M. ROGERS is in Chile.

GEORGE A. SCHROTER is now in New York.

N. SAMWELL has returned to London from Mandalay.

R. S. BOTSFORD is in London, on his return from Borneo.

GEORGE W. MAYNARD has left New York on his way to Mexico.

FRANK WESTERN returned to Egypt at the end of September.

MARTIN SCHWERIN has returned to New York from Tennessee.

O. E. JACKSON is manager Big Giant M. Co., near Boise, Idaho.

C. B. KINGSTON left London on September 9th for South Africa.

BEN S. REVETT is going shortly to Colombia to examine placer ground.

MARTIN H. HELLER has returned to San Francisco, Cal., from New York.

W. C. HOWARD of San Francisco, Cal., has returned to his mines near Camp Mohave, Ariz.

G. E. ALEXANDER is manager Middle Yuba gravel mine, North Columbia, Nevada county, Cal.

ROGER TAYLOR has been appointed assistant superintendent Tacoma Smelting Co., Tacoma, Wash.

ERNEST RAMMELMEYER is superintendent Iron Springs M. Co., at Iron Springs, Washington county, Idaho.

E. L. DE LESTRY of St. Paul, Minn., manager Arizona & Eastern Con. M. Co., has been at the mines near Globe, Ariz.

E. H. COOK has resigned as manager Santa Francisca mine, Asientos, Aguascalientes, Mex., and is in Los Angeles, Cal.

F. A. HILL of Renton, Wash., has been appointed general manager Canadian Coal & Coke Co., Frank, Alberta, B. C.

FREDERICK GRUNDY has gone to the City of Mexico to make an extended trip examining properties in southern Mexico.

F. H. JOHNSON has succeeded G. W. Root as superintendent New York Grass Valley mine, Grass Valley, Nevada county, Cal.

W. J. BELCHER, superintendent White Bear mine, near Downieville, Cal., has been examining mines in Mohave county, Ariz.

NORMAN CARMICHAEL has resigned as manager Highland mine, Ainsworth, B. C., to take charge of some of the Arizona Copper Co.'s mines near Clifton, Ariz.

H. SCHIEFFLEIN, assistant manager mining and crushing machinery department Allis-Chalmers Co. of Milwaukee, Wis., is in San Francisco, Cal.

G. F. RENDALL, consulting engineer American Lead Corporation, with headquarters at 120 Liberty street, New York, is examining the Bullychoop mines, Shasta county, Cal.

IT is stated on good authority that W. J. Chalmers, who was until September 7th last the vice-president and treasurer, and also a director of Allis-Chalmers Co. since its organization, has resigned as director, and that he has sold all the shares of stock held by him, so that he is therefore no longer connected with the company.

W. F. WAGNER, general manager Wm. Jessop & Sons, Limited, in the United States, together with E. L. Hand, who represents them in Philadelphia; E. W. Salisbury of Warren Salisbury & Nightingale, their agents in Providence; R. B. Ridgley, their representative in Detroit, together with F. W. Babcock of the Standard Oil Co., resident of Providence, sailed on the Cunard steamer Caronia, October 3d, to attend the 282nd annual gathering of the Cutlers Co., at their banquet in Sheffield on October 12th. On this occasion S. J. Robinson, managing director of Wm. Jessop & Sons, Limited, will be installed as Master Cutler, a position of great honor and social and commercial influence.

Commercial Paragraphs.

THE Chas. C. Moore Co. of San Francisco, Cal., have a contract from the Tonopah M. Co. for a 100-stamp mill to be operated by electric power.

Trade Treatises.

A neat booklet on "Coal Mining Machinery," from the Ingersoll-Sergeant Drill Co. of 11 Broadway, New York City, illustrates and briefly describes the "New Ingersoll" and the "Radialaxe" coal cutters, the "Haeseler"

coal boring machine, the "Little Jap" hammer drill and air compressors.

Catalogue "C" of the C. H. Shaw Pneumatic Tool Co., 35th and Wazee Sts., Denver, Colo., describes the Shaw Eclipse air hammer rock drill and the Eclipse Pneumatic hammers. It contains valuable information on operating the drills, besides full description of their construction.

Books Received.

"Proceedings of the American Institute of Electrical Engineers," Vol. XXIV, No. 9, September, 1905.

"Preliminary List of Deep Borings in the United States," by N. H. Darton, forms Water Supply and Irrigation Paper No. 149 of the United States Geological Survey. It is arranged according to States and counties, and reports all wells and borings more than 400 feet in depth.

"Second Year Chemistry," by Edward Hart, a hand book for laboratory and class work in qualitative analysis of the commoner metals and non-metals, with a brief introduction to methods of quantitative work. This is an elementary treatise containing little to differentiate it from scores of similar manuals already written. It is published by the Chemical Publishing Co. of Easton, Pa., for $1.25, and will be sent postpaid by the MINING AND SCIENTIFIC PRESS on receipt of price.

As extracts from "Mineral Resources of the United States for 1904," the United States Geological Survey has issued "Potassium Salts," by W. M. Courtis, containing a short sketch of the German potassium salts industry, and a discussion of the possibilities of finding potassium salts in the United States; "The Production of Aluminum and Bauxite in 1904," and "The Production of Cement in 1904," by L. L. Kimball, with notes on average characteristic tests of cement in the United States.

An ever-increasing demand for timeliness and for the concentration of information has been met in "Pyrite Smelting," edited by T. A. Rickard, from a series of discussions in the Engineering & Mining Journal. The volume is a revised reprint of these discussions thus brought together in more convenient form than afforded by the files of a journal. The contributions are essentially answers to a series of ten pertinent questions on the subject, submitted to a number of prominent metallurgists. These questions were: 1. What types of ore are suited to pyrite smelting? 2. Is hot blast advisable? 3. To what extent can fuel be eliminated? 4. What amount of copper is required for the collection of the precious metals? 5. What percentage of lime is necessary to a clean slag? 6. What percentage of zinc in the charge can be treated profitably? 7. What is the degree of sulphurization attainable? 8. What are the possibilities as to capacity of furnace? 9. What are the limitations of the process? 10. What is the relative economy as compared with rival processes? These questions were answered by L. S. Austin, E. P. Mathewson, Walter E. Koch, S. E. Bretherton, F. R. Carpenter, W. R. Ingalls, R. L. Lloyd, W. T. Keith, Herbert Lang, L. D. Godshall, William A. Heywood, G. F. Beardsley, Thomas T. Read, Henry W. Edwards, Charles H. Fulton, P. Wiseman, W. H. Nutting, W. H. Freeland, E. A. Weinberg, Amado Buen, Edward D. Peters, Hiram W. Hixon, S. Dillon-Mills, Lewis T. Wright, Charles S. Palmer, P. L. Marston, J. Parke Channing, W. Randolph Van Liew, George W. Metcalfe, James W. Neill and C. H. Doolittle. These contributions give the views of each smelterman on the questions submitted, and also on many other points of practical smelter running. The subject is important, and this book contains the latest and best information relative to it. It is eminently practical. It is current, not ancient, history, and being a live subject it is necessarily incomplete. The book is for sale by the MINING AND SCIENTIFIC PRESS for $2.

The Bimonthly Bulletin of the American Institute of Mining Engineers contains a number of technical papers. These may be roughly classified as relating to geology, metallurgy of gold and silver, iron treatment, coal mining, and miscellaneous subjects. Of the first class, J. E. Spurr's "Genetic Relations of Western Nevada Ores" has already appeared as reports of the United States Geological Survey. In "The Magmatic Origin of Vein Forming Waters in Southeastern Alaska" A. C. Spencer correlates the geology of Alaska with that of California, and discusses a theory of the vein formation that may be of value if borne out by further field work. Edward Hake, in discussing H. M. Chance's paper on the "Taviche Mining District," near Ocotlan, Oaxaca, Mexico, presents additional detail regarding the geology of this district. The precious metal metallurgy is confined to a theoretical paper by Herman Poole on "Kernal Roasting" and a discussion by T. K. Rose on H. O. Hofman's paper on "The Effect of Silver on the Chlorination and Bromination of Gold." J. E. Johnson contributes a paper, "Notes on the Physical Action of the Blast Furnace," H. R. Hall "The Use of a High Percentage of Fine Ores in a Charcoal Blast Furnace." Mansfield Merriam discusses H. H. Campbell's paper on "The Influence of Carbon, Phosphorus, Manganese and Sulphur on the Tensile Strength of Open Hearth Steel," and a number discuss J. P. Roe's paper on "The Manufacture and Characteristics of Wrought Iron." "The Classification of Coals" is discussed by M. R. Campbell, who concludes that carbon-hydrogen ratios form the most satisfactory basis for coal classification, being better than fuel ratios, calorific value or carbon. He also treats on "The Commercial Value of Coal Mine Sampling," giving some practical points as to how it should be done. S. B. Christy presents a paper on "Present Problems in the Training of Mining Engineers," upon which comment has already been made in these columns. "Geological Mine Maps and Sections" are shown by D. W. Brunton, who proposes that more use be made of the map in mining work. Biographical notices are given of Sir Lowthian Bell and B. W. Frazier Jr.

Latest Market Reports.

SAN FRANCISCO, October 13, 1905.

METALS

SILVER.—Per oz., Troy: London, 28⅜d (standard ounce, 925 fine); New York, bar silver, 61⅛c, refined (1000 fine); San Francisco, 61⅛c; Mexican dollars, 48c, San Francisco; 47c, New York.

COPPER.—New York: Standard, $16.37½; Lake, $16.37½@16.75; Electrolytic, $16.62½; Casting, $16.12½@16.37½. San Francisco: $16.50. Mill copper plates, $17.50; bars, 18@24c. London: £71 5s spot per ton.

Several weeks ago the report was sent out that a bear raid would be made, not only on copper mining stocks, but also on the metal. It was pointed out in these columns at that time that any attempt to depress the price of copper would have only temporary effect, if any at all, as the industrial condition of the country, the increasing demand for the metal, and the fact that the production barely keeps pace with the demand, all were against a slump in prices. The statement made at that time—September 9—has been proven to be correct. Copper is stronger to-day than at that time. The monthly reports of the large companies show no material increase, if any at all, in production, while the demand still holds good for the various grades of metal.

Following are the figures of German consumption of foreign copper for the months from January to August, 1905, as compared with the same period of time for 1904 and 1903:

	1905.	1904	1903.
Imports, tons	73,234	74,482	56,094
Exports, tons	8,254	5,610	6,964
Consumption, tons	64,980	68,872	49,130

LEAD.—New York, $4.95; St. Louis, $4.90; San Francisco, $5.00, carload lots; 5½c 1000 to 4000 lbs.; pipe 7½c, sheet 8, bar 6¾c. London: £14 12s 6d ℔ long ton.

SPELTER.—New York, $6.10; St. Louis, $5.75; London, £28 ℔ ton; San Francisco, ton lots, 7c; 100-lb lots, 7¾c.

TIN.—New York, pig, $32.00@32.35; San Francisco, ton lots, 34c; 500 lbs., 35c; 200 lbs., 36c; less, 37½c; bar tin, ℔ lb., 40c. London, £147 2s 6d.

PLATINUM.—San Francisco, crude, $18.50 ℔ oz.; New York, ingot, $20.50 ℔ Troy oz. Platinum ware, 75@$1.00 ℔ gram.

QUICKSILVER.—New York, $40.00@$40.50, large lots; London, £7 5s 0d; San Francisco, local, $38.00@39.00 ℔ flask of 75 lbs.

BABBITT METAL.—San Francisco, No. 1, 10½c; No. 2, 8c; No. 3, 7½c; extra, 17½c; genuine, 32½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 22.00c; San Francisco, Plumbers', 100-lb. lots, 19.15c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c; dust, ℔ lb., 10c; sulphate, ℔ lb, .04c.

NICKEL.—New York, 55@60c ℔ lb.; ton lots, 40@47c.

ALUMINUM.—No. 1, 99%, small lots, 37c ℔ lb.; 100 lbs., 35c; 1000 lbs. 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $15.25; gray forge, $14.75; San Francisco, bar, 3½c ℔ lb., 3¾c in small quantities.

STEEL.—Bessemer billets, Pittsburg, $21.00@$24.00; open hearth billets, $23.00@$25.00; San Francisco, bar, 7c to 13c ℔ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 7¾c; less than 500 lbs., per lb., 8c; in 25-lb. tin pails, ½c ℔ lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 7½c; do. in kegs, 8c.

LIME.—Santa Cruz, $1.35 country, $1.25 city ℔ bbl.

CEMENT.—Imported, $3.00@4.00 ℔ bbl.; California, carload lots, $1.80 f. o. b. at works; small lots, $2.10 ℔ bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

LUMBER.—(Retail): Pine, ordinary sizes, $24.00@25.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50@5.00; pickets, $21.00; shingles, $2.50 for No. 1, and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00@35.00.

NAILS.—This week the basic prices are: Wire, $2.77; Cut, $3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d, Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4d and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 13½c; Hallett's, 14½c; San Francisco, 1000-lb. lots, 14c; 300@500-lbs. 12c; 100-lb. lots, 13c.

BISMUTH.—Subnitrate, ℔ lb., $2.10.

BONE ASH.—Extra No. 1, 5@6c ℔ lb; No. 1, 4@5c.

BORAX.—Concentrated, 7@8c ℔ lb; powdered, 9@10c; fused, 25@30c; crystal, 7c.

CANDLES.—Spear Brand, 16 oz. adamantine, 40s., 11c ℔ set; 14 oz. adamantine, 40s., 10c; 12 oz. adamantine, 40s, 9c; 10 oz. adamantine, 40s, 8c; 16 oz. stearic, 40s, 12¾c ℔ set; 14 oz. stearic, 40s, 11½; 12 oz. stearic, 40s, 10¼c; 10 oz. stearic, 40s, 9¼c. 100-case lots and over, ½c less. Not less than 50-case lots, ¼c less. Boxes of 20s, price ½c advance.

CAPS.—3x, $5.50@6 per 1000; 4x, $6.50@7; 5x, $8@8.50; Lion, $9@9.50, in lots not less than 1000.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c ℔ lb.; caustic soda, in drums, 3@3½c ℔ lb.; Cal. s. soda, bbls., $1.10@1.20 ℔ 100 lbs.; sks., 90c@$1.00; chlorate of potash, 12@13c; nitrate of potash, 6¾@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2¾@2¾c; flour sulphur, French, 2¾@—c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 5¼@5¾c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66% B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

CHROMIUM.—90% and over, ℔ lb., 80c.

COAL.—San Francisco, coast, yard prices: Wellington, $8.00; Seattle, $6.50; Coos Bay, $5.50; Southfield, $8.00. Cargo lot, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $13.00; Cannel, $8.50; Welsh Anthracite, $13.00; Rock Springs, $8.50, long ton; Colorado Anthracite, $14.00. Coke, $11.50 per ton in bulk, $13.00 in sacks; Sunnyside, $8.50, long ton.

FIRE BRICK.—Domestic, carloads ℔ 1000, f. o. b., factory square, $25.00; soap and split, $22.50; arch and wedge, $27.50; skewback, $30.00; circle, $32.00.

FIRE CLAY.—Domestic, ℔ ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, $8.50.

FUSE.—Triple tape, $4.00 per 1000 feet; double tape, $3.55; single tape, $3.10; Hemp, $2.85; Cement No. 2, $3.10; Cement No. 1, $2.75, in lots of 3000 and up.

OILS.—Linseed, boiled, bbl., 54c; cs., 59c; raw, bbl., 52c; cs., 57c; Lucol oil, boiled, bbl., 51c; cs., 56c; raw-bbl., 49c; cs., 54c. Kerosene—Pearl, per gal., 17½c; Astral, 17½c; Star, 17½c; Extra Star, 20½c; Eocene, 19½c; Elaine, 26c; Water White, in bulk, 11c; Mineral Seal, iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 14½c, do., cs., 21c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 12½c; do., in cs., 19c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 57½c; cs., 62½c; Sperm, crude, 63@68c; Natural White, 68c; Bleached, do., 57c; Whale Oil, cs., 52@67c.

LITHARGE.—Pure, in 25-lb. bags, 9½@10½c ℔ lb.

MAGNESIUM.—Pure, N. Y., $1.60.

MANGANESE.—Black oxide, ℔ lb., 2¾@4c.

MERCURY.—Bichloride, ℔ lb., 77c.

MOLYBDENUM.—Best, $2.75 ℔ lb.

PHOSPHORUS.—American, ℔ lb., 70c.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1**, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2**, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

RED LEAD.—500 lbs. and over at one purchase, ℔ lb. 7½c; less than 500 lbs., 7¾c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 54c

SODIUM.—Metal, ℔ lb., $1.

TUNGSTEN.—Best, ℔ lb., $1.20.

URANIUM.—Oxide, ℔ lb., $3.40.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 350 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING SEPTEMBER 26, 1905.

800,534.—TELEPHONES—Andriano & Herbstritt, San Francisco.
800,260.—HORSE WEIGHT—T. Hellstedt, San Francisco.
800,539.—DRAFT EQUALIZER—M. H. Blanchard, Davisville, Cal.
800,356.—PUMPS—Briggs & Briggs, Yountville, Cal.
800,136.—LAWN SPRINKLER—B. Brown, Longbeach, Cal.
800,357.—VEHICLE TIRE—F. Burnham, Fresno, Cal.
800,263.—LOG RAFT—J. A. Campbell, Seattle, Wash.
800,264.—LOG CRADLE—J. A. Campbell, Seattle, Wash.
800,437.—RAIL CHAIR—R. H. Fray, Traver, Cal.
800,371.—FRUIT PICKER'S SACK—E. Harter, Riverside, Cal.
800,298.—FILTER—C. Heilrath, Sacramento, Cal.
800,374.—FOLDING BED—W. C. James, Los Angeles, Cal.
800,376.—AMALGAMATOR—H. L. Lightner, San Francisco.
800,379.—CONCENTRATOR—H. L. Lightner, San Francisco.
800,384.—BALING PRESS—C. L. Miller, Berkeley, Cal.
800 592.—CONNECTING ROD—Phillips & Walkley, Los Angeles, Cal.
800,398.—SPLASH PLATE—G. C. Richards, Oakland, Cal.
800 399.—PUMP HEAD—G C. Richards, Oakland, Cal.
800,509.—TIME BEATER—J P. Stanton, San Francisco.
800,335.—GATE—J. F. Stirton, Monroe, Wash.
800,518.—TROUSERS' STRETCHER—W. J. Wardwell, Redondo, Cal
800,252.—CONCRETE MIXER—G. W. Weller, Baker City, Or.
800,349.—TRIPLE VALVE CLAMP—O. L. Wright, Richmond, Cal.

Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

TRIPLE VALVE CLAMPS.—No. 800,349. Sept. 26, 1905. Ovid L. Wright, Richmond, Cal. This invention relates to a device which is especially designed for holding the triple valve of an air brake mechanism in place upon the inspecting and repair table. It is designed to provide a rapid, convenient, and secure holder for peculiarly shaped valve casings while the inspection or repairs are going on. It comprises a work bench or table having upon one side an upwardly projecting standard, said standard having a gasket against which a removed valve casing is fitted and having openings for pipe connections, a bent lever fulcrumed to the table standard, having one end forked to straddle the valve casing and having the opposite end extended over the table, and an air cylinder and piston for operating the lever.

DREDGER BUCKET.—No. 800,936. Oct. 3. 1905. T. O'Leary, Oakland, Cal., one-half assigned to R. S. Moore of San Francisco, Cal. The object of this invention is to provide certain improvements in dredger buckets and the connections thereof whereby the minimum of wear is effected with convenient and easy adjustment and compensation for such wear as may occur. It consists of dredger buckets having segmental shells, longitudinally disposed extensions upon one side and detachable reversible links secured thereto and forming coupling connections for the buckets; also means for relieving and distributing strains, said means comprising lips extending outwardly from one side, and links extending longitudinally upon each side and riveted to said lips, and other details of construction.

NAIL.—No. 800,912. Oct. 3, 1905. M. Hermelink, San Francisco, Cal. The object of this invention is to so construct the nail as to insure its driving properly into both the parts which are to be united, and this is effected by a novel construction of the point of the nail. The invention comprises a nail having a head at one end, a diagonally grooved channel extending from the edge upon one side of the entering end to the opposite side of the nail shank, said channel having transverse corrugations.

ANTISEPTIC TELEPHONE MOUTHPIECE.—No. 800,907. Oct. 3, 1905. W. B. Curtis, San Francisco, Cal. The object of this invention is to provide a simple, attractive, cheap and practical antiseptic mouthpiece or attachment therefor which will possess all the desired germ-destroying qualities without detracting from the appearance or the efficiency of the telephone. It consists of a telephone mouthpiece having means of attachment at one end to a telephone stand or the like, and provided with an annular flange proximate to said end, an absorbent filler inclosed by said flange, said mouthpiece having a perforated diaphragm and having ports connecting the filler chamber with a space upon each side of the diaphragm, and other details of construction.

LEYNER AIR COMPRESSORS

ARE DESIGNED SOLELY AS AIR COMPRESSORS. THEY ARE NOT MERE ADAPTATIONS OF A PUMP, ENGINE OR MOTOR TO THE PURPOSE OF COMPRESSING AIR. SEE?

CATALOGUE OF CHEMICAL TECHNOLOGY AND GENERAL CHEMISTRY.

PUBLISHED AUGUST 15, 1905.

☞ *Our Complete Classified Catalogue of Books on Chemical Technology and General Chemistry arranged under the following heads: Acids, Alkalies, and Salts; Beverages, Brewing, Cider, Distillation, Fermentation, Liquors, Preserving, Vinegar, Wine; Brick, Ceramics, Glass, Porcelain, Pottery; Cement and Concrete; India Rubber, Gutta Percha, Glue, Ink; Leather Manufacture; Oils, Fats, Waxes, Paints and Varnishes; Paper Manufacture, Fibres; Perfumery; Soap and Candles; Sugar, Starch; Flour, Baking, Bread, Confectionery; General Reference and Receipt Books. General Chemistry, Chemical Arithmetic, Calculation, Tables, etc.; Chemical Analysis; Inorganic Chemistry; Organic Chemistry; Electro-Chemistry; Addenda; sent free to anyone in any part of the world who will send his address.*

WEALTH IN SIGHT.

The Territory tributary to the

Santa Fe System

In INDIAN TERRITORY, TEXAS, COLORADO, NEW MEXICO, ARIZONA and CALIFORNIA, offers to limited investments of capital, backed by energy and brains, unusual opportunities for development of GREAT MINERAL PROPERTIES.

Deposits of the following are known to exist on and within a few miles of our lines:

Antimony, Alum, Asbestos, Asphalt, Barytes, Bauxite, Borax, Cement Rock, Coal, Cryolite, Clays of all kinds, Copper, Gold, Graphite, Gypsum, Granite, Iron, Kaolin, Lead, Lithograph Stone, Manganese, Mica, Marble, Mineral Paints, Nitre, Nickel, Natural Gas, Onyx, Petroleum, Phosphate Rock, Pumice Stone, Pyrites, Quicksilver, Salt, Silica, Strontianite, Stone—Oolite, Lime and Sand, Silver and Zinc.

For further information, address

WESLEY MERRITT,
Industrial Commissioner,
Atch., Top. and Santa Fe System,
CHICAGO, ILL.

THE trade paper costs the least and produces the most of any form of advertising.

The Disadvantages of Prejudice.

In some old mining districts, new strikes are announced in unexpected places, the find in almost every instance having been made by those who were comparative strangers to the locality and unprejudiced as to formation and other geological conditions. Recently the Queen of the Hills Company, operating in Whistler gulch, near Deadwood, S. D., made a strike in a new shaft which promises important development. The company had previously spent considerable money in the vicinity searching for a payable ore body, but until this new strike was made had found little of consequence.

Whistler gulch is a tributary of the Whitewood creek from the eastward and on the hillsides outcrop both the old steeply dipping crystalline schists of the Algonkian, and the overlying nearly horizontal formation of the Cambrian. Both formations are intruded by dikes, and there is every geological evidence there of the possibility of ore in the rocks of both ages, but until now there seems to have been little inducement to prospect for ores in the immediate vicinity of Deadwood. On the east side of the town and within its corporate limits, the geological conditions are most favorable, and the little prospecting done there years ago proved the existence of ore, but it was not found in large quantities, and development work ceased. There is every probability that intelligent prospecting on the ridge between the city of Deadwood and Spruce gulch, a mile to the eastward, would result in the discovery of payable ore, but no one having made a valuable discovery in that immediate vicinity, the inducement to try seems small. The great mass of pyritic iron-copper ore in the Whizzers mine, half a mile above Deadwood, remained unknown for years until discovered through the intelligent and energetic prospecting of the present owner of that property.

Deadwood is not alone in this. It remained for the years 1904–'05 to chronicle the discovery of some of the most phenomenal ore bodies Leadville, Colo., has ever known, after nearly thirty years of the most active kind of mining operation in that district.

Miners the world over are too much influenced by tradition and the results of the past. Their prejudices are strong and their views are not easily changed, and generally they require some strong incentive to break away from cherished theories and practices. This accounts for some remarkable discoveries made by the so-called "tenderfeet," who, untrammelled by fallacious ideas of geology, or as to the various kinds of rocks that the miner considers favorable or unfavorable for mineral, tries everything that comes in his way. He innocently picks up flint from the limestone and finds on having it assayed that it is rich in gold, as was the case in the Ragged Top district in the Black Hills.

It was only in a moment of desperation that Stratton, of the Independence mine at Cripple Creek, Colo., had some samples of rotten granite assayed, and found that it was shipping ore. He had tried everything else in the vicinity without success, and reasoned against his own belief that possibly the granite dike might be gold-bearing.

From Goldfield, in southern Nevada, now comes soft, decayed, sandy porphyry, bearing hardly a trace of free quartz, and yet some of this unpromising appearing rock carries several hundred dollars per ton. A sandstone, apparently a volcanic tuff, is also rich in gold. Rhyolite, dense and silicified, is rich in gold in some claims. A fine grained, flint-like quartz assays into the hundreds of dollars. Every day produces new evidence in that district that the miners' axiom, "Gold is where you find it," is one which should be constantly in mind when prospecting.

Waverly, Nova Scotia, Looking Southwest. Low Area in Foreground is a Fault Valley. (See Page 273.)

Government Building, Halifax, Nova Scotia. (See Page 273.)

NEWFOUNDLAND has at last developed a payable gold mine. Archæan rocks are chiefly found in that region and considerable prospecting has been done on the island, but until recently without satisfactory result. The Goldenville Mining Company are the owners of the newly developed mine, which is at Mings, on that island.

Success in Mine Promotion.

Probably not less than nine out of ten mines, which are financed by the public, are placed on the market through the efforts of promoters. As a result, the promoter has come to be looked upon as being as essential to a successful flotation as the capitalist himself. It is rarely that the owner of a mine, no matter what its stage of development, successfully places his mine before individuals, or the general public, without assistance. The promoter seems almost inevitable. In some instances the promoter seeks a mine he may offer for sale direct, or that may be incorporated and its stock placed on the market, but as often the mine owner voluntarily seeks the aid of some one experienced in the art of raising the money necessary to develop and equip mining properties. These two, working together, form a strong combination, and the usual result is, if the property possesses merit, a successful flotation. Not infrequently the flotation is successful when the property has no evident value. In the latter case success—if raising money only can be considered as success—is due altogether to the pursuasiveness of the descriptive powers of the promoter. He pictures the possibilities of the venture in such glowing terms, and his assurances are so earnest and convincing, that the uninitiated investor finds himself unable to resist the desire to take a chance. Occasionally ventures of this class turn out satisfactorily, more often they do not. Some mines are floated with comparative ease, largely on the chances of encountering the ore bodies developed in neighboring property. It is not an uncommon thing for shoots of ore to pass into neighboring ground on their downward trend, and speculative promotions based on a contingency of this kind may be classed as legitimate risks. All undeveloped mines are risks, no matter what their surface showing may be. It is only the mine having large development with abundance of payable ore in sight that may be looked upon as possessing no hazard whatever. Ordinarily, however, the valuation placed on property of this description is so high that the element of risk is still great to the prospective investor. As soon as a mine is recognized as having passed the stage of speculative value, the demand for its stock is so great that the market value quickly becomes inflated, in which case the investor may about as well put his money in a less positive proposition, while standing a chance to realize handsomely on possible developments.

Where a promoter desires to make a business of raising money for mine development and equipment, he must become a conservative, for in this way only can he protect himself from the result of unfortunate investments. The individual or company which engages in the business of mine promotion can attain the greatest success by a careful and discriminating selection of the best properties from among the many offered. Having secured by option or purchase that which seems to afford the greatest security for investment, the property is vigorously developed, the extent and character of its ore bodies determined, and the proper machinery for the treatment of the ores installed. Success usually follows this conservative method of operation and the prospect develops into a "going concern," paying a monthly net profit; and if it possesses sufficient reserves for the future, the property can be sold at a large advance on the capital invested. The individual or firm who can do this is constantly besieged by would-be investors for mines. Having thus established a reputation for reliability, and more particularly for success, it will be found difficult to supply the demand for good mines. This was the policy pursued by a large firm of mine promoters, and with almost phenomenal success. These successes were numerous, and the failures—they were charged to "profit and loss," for they never floated a mine on the public which proved an absolute failure.

Here lies the road to the highest success in mine promotion, but the lack of capital and haste to realize on any venture undertaken result in the failure of a large number of undertakings, which possibly may have become successes were less haste made to make a turn. In this is not considered that class of promotions commonly known as "wild cats," for, as a rule, the promotions of this latter class have nothing whatever to recommend them other than the promoter—generally under such circumstances a questionable endorsement.

HOW often one sees in connection with what are evidently exaggerated statements concerning mines of no great development, that "Mr. Blank, the noted mining engineer, has made the report and on its accuracy is willing to stake his professional reputation," etc. Usually the "well-known mining engineer" is neither well known nor an engineer, and has no reputation to lose. Conservative and experienced engineers are not so ready to stake their reputations upon unknown conditions in mines, for a long experience with the uncertainties of ore deposits, and the vagaries of geology, has taught them caution, and mine reports which contain these reckless risks of reputation at the expense of other people's money may usually be looked upon with some suspicion, for the chances are that the reputation at stake is but little better, if as good, as the mine itself.

A bulletin of the United States Geological Survey, on the production of aluminum and bauxite in the United States in 1904, says that aluminum is being more widely used each year for other purposes than as electrical conductors, and that usually from two to five ounces of the metal are employed in making each ton of open-hearth steel, and from six to eight ounces per ton of Bessemer steel, the object in adding the aluminum being to reduce the slag or oxide formed during the pouring of the molten steel, and had every ton of steel manufactured in 1904 been subjected to this treatment, there would have been consumed about 5,000,000 pounds of aluminum. A great many other uses are being found for the metal, and its production is likely to increase, if suitable material can be found from which it can be made at not too great a cost.

The Unsophisticated Director.

One of the most serious drawbacks to the proper and successful management of many mining properties is undoubtedly the lack of knowledge of the business on the part of the directors who usually control the destinies of the enterprise. Men are selected for the responsible position of director for various reasons, one of them being that his name may give good standing to the concern when it is desired to sell stock. Another, and more legitimate reason, is that he is chosen to represent investors, who, having every confidence in his integrity and business experience, feel that their interests will be protected. In other cases, the buyer of a large block of stock stipulates that in consideration of his election as a director he will take the stock, and the trade is made. There is always this desire to control, natural enough, too, but the men who thus seek to control should have some knowledge of mining and metallurgy, or they are of no particular value in the directorate, while their presence there may operate to the disadvantage of the enterprise. A managing director of a European mining company visited the company's property in the West some years since, and while at the mine asked the most absurd questions, showing that he knew nothing of even the rudiments of mining, and yet this concern was placed wholly in his hands, and as may be expected under such circumstances, it was a dismal failure. He had been responsible for the purchase of the property in the first place, and, too late, discovered there was not enough ore available to keep the mill employed. In another instance, the president of a mining company, and also a director, visited his mine and remained a week or more, a close observer of everything. One day he said to the superintendent, "I see you don't hoist the same amount of ore every day—sometimes 100 tons, and sometimes over 200 tons. How much can that engine hoist in 24 hours?" On being informed that it could easily handle 1000 tons daily, he gave orders to hoist no less than that amount as long as the engine could do it, and when it failed the company would supply another. These things seem amusing, but they have another than a humorous side. If men of this stamp have the business sagacity and experience usually attributed to them, they should realize that they know nothing about the business, and should be contented to learn before presuming to dictate the policy of the management. Mining is a business requiring years of study and experience. It cannot be learned in a day any more than can the law or medicine, or steel making, or any other great business or profession. It has more phases, and more changing features, than any other business in the world. The condition of the mine changes daily; the ore changes more or less from level to level; the metallurgical methods usually undergo many changes during the life of the mine, and the whole proposition presents a multitude of ever shifting conditions which only knowledge, gained by experience, can master; and yet the unsophisticated director very frequently is a dominating factor in it all.

THE "lateral secretion" theory of ore deposition still has its advocates—mostly among the older members of the mining fraternity. One strong argument in support of this theory is that the evidence of the mineral in the vein having been derived from the adjacent walls is in the sulphide minerals found in the wall rocks. Those who favor the theory which attributes the filling of veins, zones and other forms of ore deposit to ascending solutions, argue that the sulphide minerals in the wall rocks were deposited therein from the same solutions as those which produced the ore deposit itself. Assays made of country rock in a mineralized region usually give small returns in the precious metals, as well as often in iron, copper, zinc and lead sulphides, and in some instances these values increase as the walls of the deposit are approached. The advocates of both theories point to the same deposits to prove the soundness of their judgment.

Mining Laws in Alaska.

The extensive location of mining ground in groups of claims in Alaska has been the cause of much litigation up to the present time. An important question which arose in the progress of this litigation was: "What constitutes a valid discovery?" Another matter which came up for judicial determination was: "Is a single discovery sufficient to base a group-claim of eight locations upon?" Some of the locations were made upon the discovery of fine colors of gold in the surface alluvial and moss, and all of the group locations, as far as known, were predicated upon a single discovery. The Alaska court instructed the jury that a discovery should be of such a nature as to justify a reasonable man to perform work upon the claim, and also instructed them that a single discovery on a tract of 160 acres was insufficient—that a discovery must be made on each of the 20-acre tracts constituting the group claim. Concerning this important matter, "Lindley on Mines" says, Sec. 438: "Where more than one person (not exceeding eight) participate, an area equivalent to twenty acres to each is permitted; but they locate the whole area jointly, becoming tenants in common thereof, and are not, according to the practice, required to each locate a particular specified 20-acre tract. Such being the case, the question has arisen as to whether one discovery within the limits of the entire area appropriated by an association of persons would be sufficient upon which to base a location as to such area, or whether a discovery is necessary upon each 20-acre tract, or unit of location. In case of lode locations, where an appropriation in excess of the statutory limit of a single location is desired, a separate discovery and separate location are necessary.

"In applying the law to this class of cases (placers), the land department follows the rule that only one discovery is required where a location is made by an association of persons; this, however, has not always been the ruling of the department in such cases; but it is now the settled law, so far as the department is concerned, and there is little reason to apprehend any change. The Supreme Court of Montana was committed to this view even before the land department reversed its older rulings. * * * * * The department holds that one discovery is a sufficient prima facie showing of the character of the entire tract; but it is not conclusive, and the character of the remainder of the tract may be investigated. The wisdom of this rule is peculiarly manifest when we consider the difficulties which would otherwise be found in the locating of deep placers and petroleum lands. * * * * * Ground selected as placer must be mineral land, non-mineral surface not being permitted as an incident to a placer claim."

The above is in accordance with the rulings of the land department at Washington and is not a Supreme Court decision. The last paragraph is important in that it does not discriminate between ordinary placers, where the entire mass of material from surface consists of "wash"—that is, the sand, gravel, cobbles and boulders, characteristic of ordinary placer deposits, and those not having these typical features. As gold is found in superficial detritus that is not at all rounded, and yet where the gold has been derived directly from veins or pockets in the rocks of the vicinity, and situated at some higher point, and as most placer deposits have a covering of loam and soil, on which is usually a growth of vegetation, surface discovery is not always possible. In some instances several feet of this non-auriferous material must be passed through before a color of gold can be found. The deep ancient rivers of California are in many places buried beneath lava flows sometimes 1500 feet or more. No surface discovery is possible in such cases. The law, while applying to the majority of instances, makes no provision for these particular and unusual ones.

The question has also arisen in Alaska: "What constitutes a sufficient discovery?" This is directly in line with the foregoing and formed an important feature of the suits recently tried in the far North. The Alaska court, like those of the United States, has failed to arbitrarily fix this point, contenting itself with saying practically that the amount of mineral found at discovery should be sufficient to justify a reasonable man in following it up by development work. The personal equation is here a very large one. One man may place a very different estimate on the value of his discovery from that made by another person at the same place. One may see in the discovery so little evidence of commercial success that he passes on and seeks a more promising place, while another man is perfectly satisfied to take his chances with the discovery and proceeds to locate according to law. The courts have never held that mineral in paying quantities must be found in order to make a valid location. Such a theory, if carried out, would make most mining locations legally impossible. In this matter Judge Hawley said: "It would prohibit a miner from making any valid location until he had fully demonstrated that the vein or lode of quartz or other rock in place bearing gold or silver, which he had discovered, would pay all the expenses of removing, extracting, crushing and reducing the ore and leave a profit to the owner. If this view should be sustained, it would lead to absurd, injurious and unjust results."

The principal difficulty, apparently, in Alaska has been that the locators of large tracts have failed to work their claims, beyond the making of a discovery and setting their stakes or monuments, holding the ground evidently for speculative purposes. Those arriving later, and, finding long stretches of the creeks located and no work in progress, naturally set new stakes and began mining operations in earnest, which resulted in much litigation, the most of which still remains unsettled. The Federal mining laws are such that these original locators may legally do just what has been done in Alaska, thus retarding the development of the country. What the mining districts of Alaska should do to remedy this evil is to pass local laws or rules requiring a stipulated amount of work to be done on each claim as a part of the act of location. The several States have the legal right to make legislation of this character, and the several mining districts of the States and of Alaska may do the same, and so long as these laws or rules are within the bounds of reasonable requirement, there is little doubt the courts would sustain the rules of a properly organized mining district.

FOR fifteen years the once noted Long and Derry mine, on Long and Derry hill, at Leadville, Colo., has been closed by litigation. The difficulties have been settled and the property is once more to go into active operation. Considering the losses to both sides in lawsuits of this kind, and they are not at all uncommon, it seems strange that the contestants do not more frequently meet on a common ground and compromise their differences. In most instances such course would be to the advantage of both sides to the controversy, but compromise is seldom a feature of these conflicts. Nearly every important mining district of the West has seen the effect of almost interminable litigation, and in many cases the conditions were so perplexing that it made impartial decision of the questions involved nearly impossible. The natural result has been the creation of a vast amount of legal precedent, not in the statutes, and commonly known as judicial legislation. The differences of opinion between noted engineers when on the witness stand in these cases was naively summarized by a prominent engineer as "probably representing the large financial interests at stake." In at least one mining district of the Southwest the owners of adjoining large and valuable properties have forestalled the expenses and difficulties arising from the extralateral right by drawing arbitrary lines between their properties, neither claiming the right to follow their ore bodies beyond the boundaries of their claims.

IN the concentration of ores of any particular kind the same methods cannot always be arbitrarily pursued with success at different mines. Take, for instance, a quartzose gold ore, in which there is but 1% to 3% sulphides. These are comparatively rich and must be recovered by concentration, after having been reduced to pulp by stamping or otherwise. These sulphides are not always similar in different mines, and there is often a vast difference in them from different parts of the same mine. Some sulphides crush in granules and are saved without great difficulty. Other kinds break up in thin, flaky plates, and these latter—though of approximately the same specific gravity—are far more difficult to handle on concentrating machines unless hydraulic classification be first resorted to. It is a physical impossibility to separate from the gangue both granular and micaceous sulphides by a single operation on any kind of a concentrating machine. The mechanical movements, grade of machine and volume of water which will permit a saving of one will result in the loss of the other. The hydraulic classifier effects a separation of these various kinds of sulphides, and the subsequent treatment is greatly simplified. The classification may be carried out to any desired length, by arranging the classifiers in series, the products from the several classifiers going to different machines. The result is usually satisfactory, if the plant is properly designed and in charge of an experienced operator.

THAT the design of stamp and concentrating mills should, by this time, have been reduced to an exact science, all will doubtless agree, but judging from the constructive features of a large number of so-called modern mills it has not, as yet, reached this happy stage, or, if it has, the average constructing engineer or millwright has not become aware of the fact. One would naturally think that after more than half a century of experience in every corner of the world where mining is done that certain underlying principles in mill design would have long since been recognized and adopted generally as the best practice, but such appears not to be the case. The same kind of mistakes are daily made that were made thirty years ago. The average mill builder seems to pride himself upon the individuality of his own ideas, and seeks no further than the horizon of his own experience for suggestions as to what is best for each individual case. The result is that one must seek far to find the model mill. Variations in the character of ores require that they be subjected to somewhat different treatment, but in the mechanical design, the handling of material, etc., there continues to be a great divergence of opinion as to what is the best practice. Some mills are far superior to others in this respect, but one has not to look far in the mining regions to find monuments of stupidity that are astonishing.

THE gold fields of Nova Scotia have attracted more or less attention for a half century past, and a great deal of gold has been produced from the veins of that region, much of it in a primitive manner. The geology of that gold region is particularly interesting and has been the subject of professional investigation by a number of geologists and engineers. The latest to give attention to these fields is T. A. Rickard, who elsewhere herein begins a series of papers descriptive of that section. In the earlier days of mining in Nova Scotia a great deal of gold was taken from the rich small veins by men having no better tools than hammers and rocks. The quartz, rich in free coarse gold, was broken off from the ledge and pounded with a hammer on hard boulders, thus freeing the gold from the matrix.

THE possibilities of electrical power development of Victoria falls on the Zambesi river, in South Africa, continue to attract attention, and a commission of engineers has been appointed to visit the great plants at Niagara Falls to study the methods and installations there with a view to duplicating these methods of application. The falls of the Zambesi are about 400 feet in height, and a large volume of water is passing in the driest season, but the amount in the wet season is many times greater than that at Niagara. The power, consequently, which may be developed there is tremendous, and long distance installations are possible, which may equal, if not surpass, any similar installations in either Europe or America.

THE province of Ontario, Canada, contemplates a revision of its mining laws at the coming legislative session, and it has been suggested by some of the leading mining men of that province that a stipulated working condition should be required of all locators of mining lands, and that it be strictly enforced, while idle mining property be taxed heavily. It is thought laws of this kind, if passed, will have a tendency to develop the mineral resources of the province more rapidly than under the existing laws.

CONCENTRATES.

A SALT, in chemistry, is any acid in which one or more atoms of hydrogen have been replaced by metallic atoms or basic radicals.

TIN occurs chiefly as the oxide (cassiterite) and as the sulphide (stannite). It also occurs in small amount associated and in combination with other minerals, such as copper.

THE amount of water usually fed to a 5-stamp, rapid drop battery is about 1.5 cubic feet per minute. In some mills more than this amount is used and in others less, depending on the character of the ore.

THE air pressure employed in copper blast furnaces varies from 36 to 40 ounces at the blowers and from 30 to 34 ounces at the furnaces, the difference being due to frictional loss in the pipes and furnace connections.

FLAT HOISTING ROPES possess one advantage over round ropes of having every strand visible, and broken wires or other defects are therefore more easily detected in flat than in round ropes, but round ropes are preferable in other respects.

MATTE SMELTING is defined by Lang as "the smelting of natural sulphides, with the design of collecting their valuable parts in a quantity of artificial sulphides." There are various kinds of matte—iron matte, copper matte, lead matte, silver matte, etc.

ALL mines producing black or gray sands should be tested for the minerals they may possibly contain. Streams heading or running through basaltic rocks or dark colored greenstones, serpentine, and other basic rocks will contain an unusual amount of magnetite, but these same sands may also contain chromic iron, and more rare and valuable minerals.

THE "market for burros" in any particular locality is a matter upon which no exact information can be given. On general principles, it may be assumed that in a district where much prospecting is in progress there would be a demand for these useful animals, particularly on the desert, where they can subsist on less than almost any other beast of burden. Southern Nevada should afford at present a good field for the burro stockman.

STATISTICAL information concerning the yield of the Eureka mine at Sutter creek, Cal., are not available, but it is known that over 30,000 tons treated about 1868 returned gold at the rate of about $20 per ton. The cost of mining at that time was $4 to $5.25, and the cost of milling $2.15 per ton. The average pulp assay was said to have been $27 per ton. The tailings, consequently, contained an average of $7 per ton. The total output of this mine is said to have been $18,000,000.

NEARLY all if not all of the ores of copper are derived by alteration from chalcopyrite, in a more or less direct manner. Chalcopyrite is the normal ore and, in deep mines producing sulphide ores only, chalcopyrite is practically the only copper-bearing mineral present. There is a great variety of copper-bearing minerals, including oxides, carbonates, silicates, sulphides, and more complex compounds of copper with lead, zinc, arsenic, iron, antimony, etc. With these latter it is not uncommon to also find gold and silver.

THE knowledge of the average cost of gold milling in California is not imformation of any particular usefulness, for at each mine the conditions and character of the ore vary more or less. On the Mother Lode, in El Dorado, Amador, Calaveras, Tuolumne and Mariposa counties the average cost is about 40 cents per ton. In the Grass Valley and Nevada City region and on the East Lode the expense is somewhat greater, in some instances reaching $1.50 owing to character of ore, character and scope of operations and local conditions.

SKIPS possess the advantage over cages of taking on the load immediately upon the arrival of the skip at the loading pocket, no waiting for the arrival of cars being necessary, as is not infrequently the case where cages are employed. On reaching the surface the skip dumps automatically into a bin provided for the purpose, and may be sent immediately back into the mine if desired, without intervention of workmen other than the engineer. This effects a saving of labor on the surface. At some mines the skips are loaded as well as dumped automatically.

THE solid residues of gummy and tarry appearance, which result from the evaporation of crude petroleum, are all soluble in alcohol and ether, but insoluble in water, therefore, any gummy substance found in the rocks, which is soluble in water, is not one of the products of the natural evaporation of petroleum. There are numerous organic substances which have much the same appearance as the residual products of evaporated petroleum, among them being the excretions of rhodents and other animals deposited in caves and in fissures in the rocks.

IT is better to have abundant plate surface in a gold mill. Too much is better than too little. The stream should be spread out in a thin sheet, with not too heavy a grade—just enough to keep the sands from banking upon the plate. Too much water should be avoided on the plates. If there are still considerable values in the coarse quartz grains, the rock should be crushed finer to free this gold.

A "DAP," in the mine timber framer's vocabulary, is the name given to the shallow cut made entirely across a shaft plate to receive the posts at the corners, and sometimes between the corners on the wall plates. In some cases where the posts are smaller than the plates, the daps, being cut the size of the posts, may be likened to shallow mortises. They are cut on both the upper and lower sides of the plates and serve to keep the posts from shifting.

IN sampling faces of ore in the oxidized zone of a gold mine, it not infrequently occurs that the fine material contains much more gold than the hard, firm ore. The sampler must guard against being salted by this kind of material. Usually the soft, fine portion of the ore disappears with shallow depth and only the hard, normal ore remains. It is necessary to get samples representing normal, and not enriched, conditions. Many who make mine examinations are deceived by the fine prospects found in the oxidized zone, being unable to duplicate them in the deeper part of the mine.

ELECTRO-MAGNETIC separators work continuously, and by an ingenious arrangement of electric currents of varying intensity on the several magnets, a differential separation of the various minerals in black sands from beaches and river beds can be effected. Among the minerals separated from the sands containing them are magnetite, chromite, zircons, hematite, monazite, garnets, quartz, etc. The non-magnetic minerals of comparatively low specific gravity can be easily separated from the heavier minerals by hydraulic classification and by wet concentration on various machines.

THE nearest railroad point to the Panamint range in Inyo county, Cal., and probably the best outfitting point for a prospector intending to go into Panamint, is Johannesburg, in Kern county, Cal. In former years many prospectors going to Panamint and Death Valley, Resting Springs, and that section of the desert, went in from the vicinity of Daggett, crossing the Mojave river at Fish Ponds, 4 miles above the present site of Daggett. From Daggett to Ballarat on the west side of Panamint range is nearly 100 miles. From Johannesburg to Ballarat is about 60 miles in a direct line, and somewhat farther by the Searles Borax Works.

SPLIT lagging is usually made of spruce, where obtainable, and is from 5 feet to 7 feet in length, depending on the place and the conditions under which it is used, and from 4 to 8 inches in width. The thickness is usually from 2½ to 3 inches, but for special purposes may be thicker. The cost of lagging varies greatly in the various mining districts, being about 4 to 6 cents each where the timber is abundant and easily obtainable, to 10 or 12 cents each in districts where no suitable lagging can be cut. Under some conditions lagging costs delivered at the mine much more than the highest figure here given, owing to the cost of transportation.

BISMUTH is a hard, brittle metal, with a reddish-white color and metallic luster. It looks much like antimony, but is readily distinguished from the latter by its reddish tinge of color. When heated to redness it burns with a bluish flame, forming the yellow oxide of bismuth. It is not very abundant in nature. The most important ores of bismuth are the oxide and sulphide. Its chief use is in pharmacy, and the metal must be free from impurities, particularly arsenic. Bismuth ores are roasted, after which various methods of treatment are employed, according to the ore. When arsenic is present the last traces of it may be removed by melting the metal with niter. Hydrochloric acid has little effect on metallic bismuth; strong sulphuric acid forms bismuth sulphate, and when treated with nitric acid bismuth nitrate results. Bismuth is not known to form any combinations with hydrogen. One of the producing mines of bismuth ores in quantity is the Ballard at Leadville, Colo. Bismuth ores also occur near Tucson, Ariz. Bismuth ores were reported from the vicinity of Ouray, Colo., some years since. Bismuth, or some of its ores, were reported found in placer sluices on Big Pine creek, Inyo county, Cal., some years since.

IN shaft sets it is not good practice to use corner posts of too small dimensions. Scantling (2x4-inch) would be of no practical usefulness. The posts should be equal in size to the timbers of the main set, if these are as small as 6x8, or smaller; but where larger timbers are used for wall plates (8x10 and larger), the posts should be nearly equal to the plates in cross-sectional area. In very heavy ground, or where there is likely to be any shifting of the timbers, then the posts should be the full size of the plates. No lagging is required at the corners where the posts are flush with the outside of the set. Daps should be cut in the wall plates at each corner of the shaft, about ½ inch deep, to receive the ends of the posts, both top and bottom. In instances where it is not necessary to use a "bridge" and to drive the lagging, a cleat 1½x1½ inch should be nailed to the outside of each of the wall plates, and on these the lagging may be set, extending upward to catch the lower half of the plate in the set above. After placing a lagging, it may be held in place by dropping a block of wood, or a rock between the lagging and the rock wall. In some places the wall will be found close enough to admit of using a wedge only, no other blocking being required. When figuring on sinking a shaft several hundred feet, it is a good idea to include a large amount of miscellaneous blocks, ends of planks, etc., the waste of lumber mills. These answer every purpose and take the place of the more expensive wall plate timbers, which otherwise must be used.

SALT is mineral and is subject to entry under the mining laws. The law of January 31, 1901, is as follows: "That all unoccupied lands of the United States containing salt springs, or deposits of salt in any form, and chiefly valuable therefor, are hereby declared to be subject to location and purchase under the provisions of the law relating to placer mining claims; providing that the same person shall not locate more than one claim hereunder." Prior to the passage of the above law in 1901, salt lands were classed by themselves, and were not subject to entry under any law operative throughout the public land States. Under the act of January 12, 1877, salt lands were disposed of at auction at not less than $1.25 per acre, or at private sale at the same minimum rate, in the event that the sales were not effected at auction. The operation of this act was confined to States which have had grants of salines and which have been fully satisfied. The act did not apply to the territories, nor to the States of Mississippi, Louisiana, California, Nevada, North and South Dakota, Montana, Washington, Idaho, Utah or Wyoming, none of which received grants of such lands. Under existing laws a salt claim consists of 20 acres and only one claim can be taken. Any citizen of the United States, male or female, adult or minor, is permitted to make such location.

THE several simple and primitive devices employed in separating gold from the auriferous sands or the pulverized rock containing it are the hornspoon, made from the horn of a cow or ox; the batea, of wood; the gold pan of the early California miner, and the shovel used for this purpose. In the use of either of these implements an operator, by practice, can become very expert. The hornspoon is used largely in Spanish American countries, and in the southwestern part of the United States where water is scarce. The batea is a flat, bowl-like piece of wood, circular in shape and having the appearance of a very flat cone, the slope being in a true plane from rim to center, and not curved as in crockery dishes. The gold pan is usually of sheet steel pressed from a single piece, having sides sloping at an angle of about 40°. The diameter at the top is about 17 inches, the depth 3 inches and the flat area of the bottom about 10 inches in diameter—these dimensions vary slightly. The pan is the most useful of these several implements, but the batea can also be used with good effect, and with speed in experienced hands. The knack of vanning successfully on a flat shovel is more difficult to acquire than dexterity with any of the other tools mentioned. Cornish concentration men in the tin districts become expert in the manipulation of the shovel, and can easily separate the cassiterite, copper sulphide and galena from each other by this means. The pan is so much more convenient for general hand concentrating operations that it has largely replaced all of the others in the United States.

WHEN in shaft sinking it is desired to use a crosshead there are two things absolutely essential to success and safety. First, a clip must be securely fastened to the hoisting rope, which will arrest the fall of the crosshead should it become jammed in the shaft when going down, and then, becoming released, falling. This clip must be placed so high above the bucket as to be out of reach of the men riding on the chime of the bucket or on the bail. Second, to insure further safety and to lessen the liability of the crosshead to become jammed when running in the guides, the frame should be made at least twice as high as the distance between the guides, and the shoes should be so constructed that the crosshead will have perfect freedom of motion and not be caught by any small projection or irregularity in the guides. Another matter too often neglected is the daily inspection of the guides, and of the crosshead itself, to see that they are in proper working condition. Serious accidents have occurred from failure to give the several matters here mentioned the necessary attention. The crosshead is so arranged as to move freely upon the rope down to the clip above mentioned. This can be made more secure by either turning the rope up the necessary distance above the eye to which the hook is attached, or by clamping to the hoisting rope a piece of old rope of the necessary length to take at least four clips. This, if secured at the proper height, will hold the crosshead. It is also a good idea to have a good sized cast iron washer resting on this obstruction to reduce the liability of the crosshead splitting and breaking should it fall. The crosshead being free to move when the bottom of the guides are reached, blocks placed there will hold the crosshead while the bucket continues to the bottom of the shaft. On hoisting, the clip on the rope picks up the crosshead, and the swaying of the bucket is reduced to a minimum. The blocks at the lower end of the guides should be separate from the guides, being merely pieces of timber larger than the guides themselves, spiked to the last set of timbers.

In Nova Scotia.—I.

Written for the MINING AND SCIENTIFIC PRESS by T. A. RICKARD.

Any one who is told to "go to Halifax" is apt to regard such consignment as anything but kindly. I found it far otherwise. Whence then comes this curious saying? It appears that in the days of the American Revolution, when many New Englanders remained loyal to the old country, there was a migration of families across the line into Canada. Many of these went to Nova Scotia, by way of the port of Halifax. Any American not whole-hearted in the cause of liberty was apt to be invited to follow the loyalists and get out of the country; it was meant as bitter sarcasm to be told to "go to Halifax." But all that is changed now, the American patriot and the loyal Britisher alike followed the call of their manhood and became the founders of progressive communities. Halifax has lost its stinging suggestiveness and we know it as a picturesque military and naval station, a charming city, and the gateway of a continent.

It may be said of Halifax that no other great seaport has gold mines so near to it.* Within 10 to 15 miles are the goldfields of Montague and Waverley. They were the first that I visited and they were the scene of the earliest activities. Just as Hargreaves made the discovery of gold in Australia (at Moonee Ponds on February 12, 1851), through the knowledge acquired concerning conditions in California, so also the first diggers in Nova Scotia were prompted to prospect. The farmers and fishermen on the east coast had heard of gold being found in California and Victoria within rocks resembling the slate and sandstone of Nova Scotia; they began to investigate the quartz which outcropped plentifully in their own vicinity. To John G. Pulsiver, of Musquodoboit, is given the renown of the first find; it was in the summer of 1860 and the locality was Mooseland, near Tangier Harbor. In the early reports of the Mines Department it is recorded how other finds were made successively in adjoining districts; they were made in the same way, by men who had become attracted in the search for gold by the stories blown across the world from the great diggings on the Pacific coast and in Australia, and who had become personally acquainted with the look of gold-bearing quartz by seeing it at Tangier and in the surrounding region.

From 1862 to 1904, inclusive, the total output of gold has amounted to 819,152 ounces, valued at $15,563,900, the average yield being 10 dwt. 3 gr. per ton. The largest return was 31,104 oz. in 1898; in 1904 it was only 14,279 oz., with an average yield of 4 dwt. 13 gr. per ton. It is evident, therefore, that at no time has the industry assumed proportions comparable to that of the greater goldfields of the world, and it is apparent that at this time there is less productive activity than in any year since the initial discoveries. Nevertheless, the stimulus given to the development of Nova Scotia by the men who have been, and are now, engaged in gold mining is not to be measured only by the statistics which I have quoted. The exploitation of the gold lodes has been overshadowed by that of the coal measures, which is destined to give Nova Scotia a high rank among industrial communities. The production of coal in 1904 was 5,247,135 tons, having a value of about $15,000,000 at the pit's mouth. This is only a beginning.

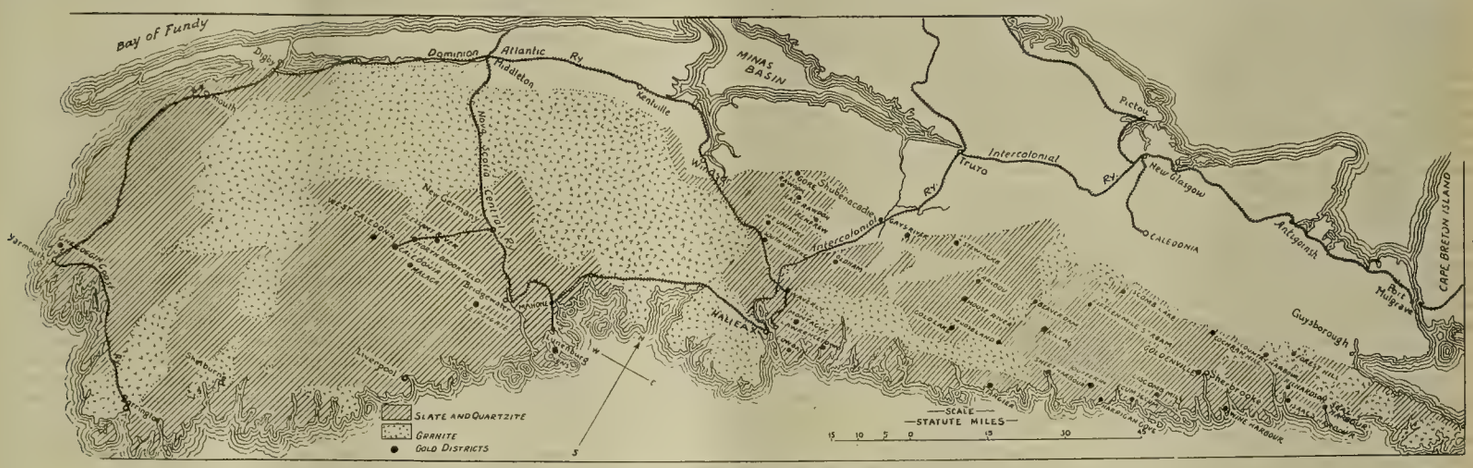
The accompanying map shows the relative position of the principal gold-mining centers. With the exception of Brookfield and Leipsigate they are east of Halifax. Mt. Uniake is due north. Most of the settlements are off the line of railway, many being situated close to the shore of the estuaries that indent the eastern coast of the province. But all of them are pleasantly accessible, the roads generally being good. Occasionally the bush is allowed to encroach, so as not only to impede a vehicle, but also to keep the track in shadow and prevent drying after rain. A mechanical scraper is employed in road making; it is expeditious and does good work. This machine scrapes the sides toward the center so as to form a crown and leave a wide gutter on each side. Broken slate packs well and makes an excellent road bed; so does granite, the feldspar of which decomposes to a cement. Near the estuaries a topping of gravel is obtained from the beach. Owing to the absence of mountainous declivities and great extremes of temperature, the roads wear well.

Decent accommodation is readily obtainable, the country folk are kindly and clean, so that no real roughing need be experienced. Simple fare is the rule, the monstrous overfeeding of our western mining camps being unknown. Fresh codfish and blueberries are important articles of diet during summer. Excellent lamb is served occasionally, but the beef is tough, for reasons suggested by the accompanying photograph, which shows that oxen are used for draught. Tea is the universal beverage; it is boiled to bitterness; real coffee is practically unknown; bread is served in a great variety of ways, as in New England. By reason of a law known as the Scott Act, it is illegal to sell intoxicating beverages of any kind, even those containing a minimum of alcohol, such as light beer or hard cider. This does not prevent the sale of intoxicants, but it does stimulate trade in cheap concoctions of an injurious kind. Drunkenness is infrequent. On the whole, I got the impression of a steady, thrifty, hard-working people, making the best of an ungenerous soil and a rigorous climate.

I am speaking of the region where they mine for gold; this is not on the trail of the tourist who knows Nova Scotia as "the land of Evangeline." The tourist goes to the Annapolis valley, a splendid tract of meadow guarded by ridges that cut off the fogs from the Bay of Funday and obstruct the cold east winds of the Atlantic. This valley, famous for its picturesque beauty and its historic associations, extends 100 miles, from Windsor to Annapolis. It is the old Acadie, the country settled by French colonists too patriotic and too much out of the world to recognize English authority after France lost dominion in North America, 150 years ago. The forcible deportation of these peasants to New England and the South, the romance of their subsequent pilgrimage and, in many cases, eventual return to Nova Scotia, have served as good material for many a writer.

But the valley of Annapolis is not typical of Nova Scotia; it is a happy vale consecrated to apples and poetry, to Parkman and to Longfellow. I saw it after four weeks of travel among the severe and monotonous scenery of a region swept of all distinction or beauty by the ruthless hand of that ice monster to whom we assign the glacial period. Partly because it is cut out of softer rock (Devonian slate and Permian sandstone) and largely by reason of the two hill ranges that flank it on the north and south, the valley of Annapolis is especially favored. The tidal rivers find a winding way deep into the pasture; the dykes, first built by the Brittany peasants, protect the interval land from the encroaching wave; the wide orchards bask in sunshine, the quiet villages sleep peacefully under gray church steeples; and on either side the hill slopes, checkered with cultivation and crested with dark forest, look down protectingly, while a wreath of fog halting over Blomidon suggests the stress and disquiet of a cold world that lies beyond this dreamland.

*The writer recently investigated the geological occurrence of gold in Nova Scotia, in behalf of the Provincial Government, but as his report has not been published he confines himself in this article, and those that follow, to the merely superficial aspects of the gold mining country of Nova Scotia.—T. A. R.



Map of the Gold Region of Nova Scotia.

It is not uncommon to find pyrite in deep gravel mines—undoubtedly formed in the bed of the stream since the deposition of the gravel. So far as known, the pyrite thus formed contains little or no gold.

Common Sense Mining.

Written for the MINING AND SCIENTIFIC PRESS by W. H. STORMS.

In 1878, M. D. Rochford and some others discovered the Standby and other gold-bearing deposits in the vicinity of Little Rapid creek, about 18 miles southeasterly from Deadwood, in Pennington county, South Dakota. These discoveries were followed by numerous others in the neighborhood, on the tributaries of Rapid creek, among them being the Paul Jones and Minnesota mines on Silver creek, the California mine on Smith's gulch, the Montezuma on Irish gulch, the Montana mine, near the head of Irish gulch, near Rochford, and the Jenny Lind and other claims at what was afterwards named Meyersville. Each of the mines above mentioned has an interesting history, and each has good prospects for making a mine. The best known of these several properties, perhaps, is the Standby, being the initial discovery of the district and the first to be equipped with a mill. On this property active development was undertaken in 1879, when a 40-stamp mill was built, power being supplied by Pelton wheels under about 150 feet pressure, the water being taken from Little Rapid creek about 2 miles above the mine, to which it was conveyed by ditch and flumes. This was a notable installation, as it was the first power equipment of the kind in the Black Hills, and for many years remained the only power plant of its kind in that region. The first superintendent, A. J. Simmons, being a California miner and familiar with the uses and advantages of water power, did not hesitate to adapt California practice to the conditions of the Hills. The Standby mine at first gave little trouble, but with depth the free gold largely gave place to auriferous sulphides. The mine was half a mile or more from the mill, and the situation was such that without a long tunnel it was necessary to handle the ore several times between mine and mill. The expense was thus unusually heavy, and the mine appeared to never run long enough at one time to permit of systematic development and operation—always working under some disadvantage. The tailings losses were high; there was not a concentrator in the Black Hills at that time and the cyanide process was not dreamed of. Since those early days the Standby has run spasmodically, with a greater or less success, under many managers. Within recent years a tunnel 1400 feet in length has been driven into the hill on a level with the upper floor of the mill and connections made with upper workings. This will greatly facilitate the operation of the mine and cheapen the cost of handling ore. The mill is being overhauled and once more gotten into running shape, and these operations will give the mine another lease of life.

The Standby, like many other mines of the central Black Hills, is low grade, and now, more than ever, requires a conservative and competent management—neither extravagance nor parsimony being possible where success is to be attained.

The Minnesota and Paul Jones mines on Silver creek had much the same sort of experience. The surface ores paid well, but with depth the sulphides so reduced the output of free gold that operations were discontinued. The California mine on Smith's gulch never reached the mill-building stage, though the mine at one time was considered one of the best in that section, and produced considerable specimen rock. The Montana mine has never had a mill, but has developed a large body of low-grade ore. The Montezuma is also in the development stage, though equipped with an experimental mill, which is not at all adapted to the treatment of the ore.

The Jenny Lind and adjoining claims at Meyersville later attracted as much attention as either of the mines above mentioned, and in 1880 a group of these claims passed into the hands of Iowa people, known as the Alta-Lodi M. Co., which proceeded to

develop the mines superficially while building a 40-stamp mill. Among other engineering exploits at this mine was the driving of a 500-foot tunnel to get 80 feet of backs, the tunnel then being extended several hundred feet beyond the highest point on its line. Several open cuts were opened on what was presumed to be the vein, and the mill was started. The water supply was too limited to admit of large and continuous milling operations, which was a detriment, in that it resulted in the cost of milling being higher than it should be. One of the most important, as well as most unfortunate features of mining at this property, lay in the fact that the management evidently conceived the idea that this mine was similar to the Homestake, and that the entire ridge on which the mine was situated would pay to mine and mill for the gold it contained. This is plainly evidenced by the several great open cuts in the hillside. The mine did not pay and was closed down permanently after several spasmodic but ineffectual attempts to overcome the difficulties of the situation.

The chief difficulty in the way of success lay in the fact that the entire mass of red and brown schist did not contain sufficient gold to pay (though assays are obtainable almost anywhere on the hill over a width of 200 feet or more). As in mines everywhere else, the gold at Meyersville occurs in shoots, or zones, which are more or less sharply defined, if not physically, at least, by relative value of the rock.

The formation is hornblende schist, through which are many lenses and veins of quartz. This quartz is of two kinds. Lens-shaped masses and stringers of granular appearance, either white or bluish in color, and vein quartz of crystalline structure — the granular appearance being entirely absent. Each of these varieties of quartz is gold bearing and each also contains iron sulphides. The color of the schists is due partly to decomposition of iron sulphides, but more largely to the oxidation of the iron minerals in the hornblende. Certain zones of the schist are so much decomposed as to have lost wholly, or nearly so, all traces of schistosity, and resemble much decayed dikes, which possibly they may be. Some of the zones of this description contain gold in payable quantities, but the values are generally scattered erratically. One place will show no gold at all on panning, when another prospect from the same streak, taken a foot higher or lower, will indicate the presence of gold to the extent of $5 to $20 per ton. The principal gold-bearing rock, however, is the schistose formation in which are numerous stringers and lenses of quartz, the exposed face in cut or drift presenting a banded appearance.

Careful sampling demonstrated that the appearance of this rock could not be trusted as a true index of value, and it is this fact, no doubt, that misled the early operators on this mine—they neglected to keep informed of values by taking the proper samples, assuming that the rock was all payable because it all looked much the same. One large cut, from which thousands of tons of ore were milled, did not pay for the mining expense, and yet, just south, and but a few feet distant, the ore was found subsequently to be not only payable, but rich. Still there was little, if any, difference in the appearance of the bodies of rock.

After several years of desultory operations the Alta-Lodi Co. permanently discontinued operations, and in 1884 the mill was removed to the Lookout mine on Castle creek, several miles to the southward. The Jenny Lind and other claims of the group remained idle for years, but eventually came into the possession of James Cochran, who still owns them. Being a practical miner, and appreciating the difference between a small vein of rich rock and a mountain mass, throughout which a little gold could be obtained at any place, the new owner spent months in prospecting the various claims. This careful inquiry into existing conditions demonstrated the fact that there were a number of places on the property where pay ore could be obtained in considerable amount. Having satisfied himself that pay ore actually existed on the property, and in sufficient amount to justify a mill, Mr. Cochran, whose means were limited at that time, put up a small Huntington mill, boiler and engine. A concentrator he thought he had no particular use for, as the rock was free milling. At first this practical, common-sense miner chose his rock with care, mined it himself, hauled it with wagon and team to his mill 1000 feet distant, and when he had accumulated sufficient ore to warrant starting up the mill, he became his own fireman, millman, superintendent and master mechanic. He supplied all the wood necessary, cutting it on the neighboring hills and hauling it to the mill. In this small way he began operations, nor has he enlarged upon them very materially. For years he has continued to work his mine during the summer months, employing such help in mine and mill as was required, and he has made a fortune from these operations. He still owns and works the mine in his own fashion, but he does it in a methodical and practical manner. Experience has taught him that because a face of ore is largely profitable, he cannot assume that after a round of holes have been blasted he can depend upon equally good results in the new face, for this has been found to be an uncertainty.

The ore shoots occur in the hornblende schist throughout a zone known to be more than 100 feet wide and several hundred feet long, and the indications are that there are other shoots in the hanging wall side which have not been developed as yet. The strike of the country generally in the vicinity is about N. 15° W., and the dip about 80° to the eastward. It has been found that the best ore in this mine occurs in the schists at places where there has been noticeable torsion of the rocks. Small displacements have taken place, and the stress causing these faults has also resulted in twisting the schists to a small but noticeable extent, together with a certain amount of crushing. Where the disturbance is most pronounced the richest ore has generally accumulated. The disturbance of the schists, as it is here called, consists of a slight foliation of the rocks, together with a more or less marked change in strike, up to 15° or 20°.

What has thus far been considered the main shoot is about 60 feet in length, and from 15 to 20 feet or more, in places, in width. Lying to the westward, and separated by about 20 feet of very low grade rock, is a second shoot. This is from 3 feet to 15 feet wide and about 160 feet in length. This latter has been opened by a surface cut almost its entire known length to a depth of 20 to 30 feet. A shaft has been sunk about 100 feet and a level run at 30 feet and another at about 60 feet from the surface. The shoot previously mentioned has been worked by open cut and shaft connected with a tunnel about 30 feet below the surface, and has produced thousands of dollars, the rock averaging $15 per ton.

A shaft was sunk to a depth of 125 feet in the main cut, but the one on which this was started dipped out of the shaft with depth, and no attempt has been made to develop the shoot at this level. East of the main shoot and branching out from the principal cut is another and smaller vein, in which good values have been found, but work has not been continued far enough to determine its relation to the ground lying beyond. On the surface considerable prospecting has been done, resulting in the discovery of several places where rich ore exists, and the indications are that all of these occurrences have something in common — in fact, all apparently belong to a system of ore deposits which in depth may be found to unite into a single large ore body. This has been proven to be the case at the Homestake, and the conditions at the Cochran mine are not very dissimilar from those at Lead, though the mineralization occurs on a much inferior scale. The most noticeable difference in the geology of the two mines, aside from their comparative magnitude, is in the lack of igneous intrusions at the Cochran mine. At the Homestake, in the upper levels, the dikes of rhyolite are a most pronounced feature, though in the lower workings they form a comparatively inconspicuous factor, but it is well known that the hornblende schists of that mine were gold bearing ages before the date of the intrusions of rhyolite. The disposition of the ore shoots at the Cochran mine is similar to that at the Homestake, and the country rock is almost identical, the chief difference being in the extent of mineralization at the two places. This difference is, of course, a most important one, but it is interesting to note how much alike the two occurrences are otherwise.

At this time the Cochran mine lacks extensive and systematic development, and consequently little is known of the existing conditions below 50 feet from the surface, but the property stands as an object lesson in what may be aptly termed common sense mining — an instance where a practical miner has made a paying proposition of a mine which, worked with elaborate equipment and large means, but inexperienced management, was a disastrous failure. The mine possessed the elements of success, these elements were discovered by the present owner by searching for them in a practical, common sense manner, and the subsequent working of the property, though almost primitive in its character, has demonstrated the unwisdom of the large equipment and extravagant operation of a mine which did not justify such outlay, but which, when properly handled, became largely profitable.

HEMATITE is frequently known to occur as a gangue mineral and associated with iron and other sulphides. In these instances the hematite is considered as of secondary importance and is not looked upon as an ore, though technically hematite is always an ore of iron. Hematite may be produced in nature from ferric iron by the action of certain carbonates and alkaline carbonates without oxidation.

Hand Sampling in Small Stamp Mills.*

Written by A. W. WARWICK.

The question of sampling is one which should receive a thorough discussion by the members of the Association. The effects of slovenly sampling methods are profound. The first and most apparent effect is that, without careful sampling, it is impossible for the metallurgist to know where the losses occur; the second effect is that incorrect methods may even point in the wrong direction; the third is that a suspicion of the samples leads to lax work on the part of every one working in the mill. The third point made might be discussed at great length with profit since, after all, laxity on the part of the mill attendants is really the source of much of the avoidable losses. The millmen, knowing that the samples cannot be used as a check against their work, naturally become somewhat careless. Nor does the effect stop at the millmen. The assayer, knowing that the samples are practically worthless, pays very little attention to their assaying. "What is the use," he says, "of carefully assaying pulps which represent little or nothing?" The result is that the mill assayer's work has become to be a reproach not only to himself but to the profession at large. Remove this suspicion as to the samples and work all along the line will be improved. And certainly millwork needs improving.

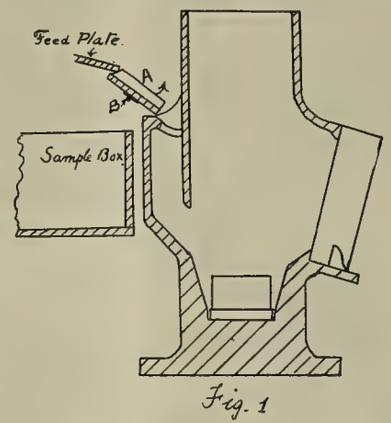


Fig. 1

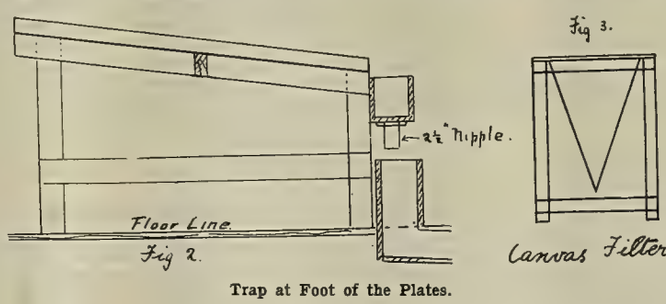
Arrangement of Feed to Facilitate Sampling.

The fact is that accurate assaying is worthless without accurate sampling, and commercially one cannot be obtained without the other.

While it is true that in large mills some effort is made to check up the work by systematic sampling, yet in most smaller mills practically no provision is made for this very important work. Where it is attempted the mill is usually so awkwardly arranged that it is practically impossible to get a correct sample. Automatic sampling is out of the question in small works, owing to the expense of installation. Hand sampling must be resorted to.

It is commonly stated that hand samples are of no value. As generally taken we must admit this current condemnation. Yet there is no reason why hand samples cannot be relied upon if, when designing the mill, provision is made for convenient and accurate sampling. The average design never takes cognizance of the question of sampling. A couple of features in the design of an amalgamation mill recently devised by the writer may be of interest. They work with perfect satisfaction and the cost is practically nothing.

It is essential to sample the ore before it goes through the mortar, owing to the general practice of employing inside amalgamation. The ore is crushed to pass a 1½-inch gauge, giving pieces ranging from 1½x4 inches down to dust infinitesimally fine. The usual practice is either to take a few pieces off the feed plate of the automatic feeder or to take out a scoopful between the ore bin and feeder, say, every half an hour. The sample thus obtained is usually



Trap at Foot of the Plates.

*Western Chemist and Metallurgist.

too low, owing to getting insufficient fines. The device for taking a hand sample is to provide a hinged flap between the feed plate and mortar. By raising the feed plate 4 inches and putting it back about 6 inches ample room will be provided. To take a sample the hinged feed spout is turned over for one-quarter of a minute and the feed is directed to a sample box, as shown in Fig. 1. By taking a sample every half hour and directing the feed for about one-quarter of a minute, about sixty pounds will be collected in every twenty-four hours from each feeder. This will give a sample the average of which in each two weeks' run (between cleanups) is quite reliable. A small crusher, set to crush to ½-inch and driven from the battery countershaft, will facilitate cutting down the samples. A riffle sampler is also very convenient.

To sample tails the ordinary practice is to run a cup along the end of the table and collect a certain amount of the pulp. The sample so collected is often ridiculously small and is rarely to be trusted; not only is there danger of vitiating the sample by the liquid pulp overflowing the cup, but particles of amalgam may be scraped off the plates. There is, therefore, danger that the tailings sample may often run higher than the headings, and indeed this often occurs.

A simple device for taking a tailing sample is to put in the bottom of the collecting launder at the end of the plate a 2½-inch nipple, so arranged that a small sheet iron spout can be put under and the whole supply of tailings diverted into a five-gallon coal oil can. (See Fig. 2.) A sample collected for about a quarter of a minute every half an hour will give a sixty-pound sample in twenty-four hours. The pulp is allowed to settle as long as possible in the sample can and the muddy water is poured off into a cloth filter, which is 12 inches in diameter at the base and 18 inches deep. The filter cloth is carried on an iron ring and supported in a wood frame, as shown in Fig. 3.

The discussions of hand sampling in connection with ore buying have conclusively demonstrated that automatic sampling is by far preferable for custom work, not only on the score of economy, but also on account of accuracy. It is here submitted that these considerations do not apply in mill work, provided that suitable arrangements are made so that hand samples can be taken with convenience. The conditions are quite different in the two cases. In custom work it is a sine qua non that the sample on each lot must represent the true value of that lot. According to the law of averages, providing no constant error is made, the buyer stands no risk even if he pays a little too much for one lot, for on the next he may even matters up by paying a little less than the ore is worth. This, however, is not satisfactory to the seller, who may only ship occasionally, and to whom the law of average does not apply.

In a mill where the grade of ore does not fluctuate between very wide limits samples taken daily will average up during a run spread over a month or two weeks, always provided, of course, that no constant error occurs. The errors in sampling will be more or less compensating. Yet the errors in milling ore, even when hand sampling, need be very small. In a characteristic case, which may be cited, we can see that the ore is pretty well mixed by the time the ore reaches the automatic feeder. In this case the ore, after being delivered at surface, goes to a sorting shed, where the ore is mixed and assorted to a very considerable extent. The ore is then trammed to the mill, where it is again mixed in the coarse ore bin. From the bin it goes to a rock breaker, from which it is spread in two streams feeding two automatic feeders of a 10-stamp mill. Each stream of ore is sampled. Thus we see that the possibility of a single car of ore being able to get through to the feeder without being at least partially mixed with other ore is quite remote. Then by taking a sample every half hour from two streams of ore it is practically impossible that a single ton can get through without having a cut or even two taken out of it. The errors of weighing and moisture determination are certainly greater than the sampling, if the samples are taken with any degree of care.

So far as the assaying is concerned it must be apparent that the samples should be regarded the same as controls and assayed in triplicate. In the case of very high single assays in amalgamation tailings, either the very high result should be rejected, or another set of assays made so as to have enough to strike a fair average. The very high result is due in most cases to a small piece of amalgam getting into the assay sample. Should the results be very irregular from day to day, either the mill work requires looking to or the sampler should be properly instructed in his work.

THE diamond bearing rock of South Africa resembles the dark green serpentine commonly found throughout the Pacific Coast region from Alaska to Southern California. In some of the pipes it presents a granular appearance, in others it is solid and massive. The source of diamonds in California still remains unknown, though most of the diamonds found in that State, if not all of them, come from a region east of any known serpentine or other peridotite rocks.

Latest Electrical Equipment of the Karawanken Tunnel.

Written for the MINING AND SCIENTIFIC PRESS by F. C. PERKINS.

The total length of the Karawanken tunnel, in Austria-Hungary, at the north end, completed up to May 17, was 4.892 kilometers. During the last 892 meters of this excavation, a considerable amount of water was encountered. Four electrically operated centrifugal pumps were installed, after a distance of 4 kilometers had been excavated, and these electrically driven pumps were increased in number to eight, and finally to ten, in order to keep the tunnel free from water while the construction work was in progress.

For the construction of the Karawanken tunnel, one of the most interesting electrical power transmission plants and equipments has been utilized. The tunnel begins at Rosenbachthal, South Valden, on the Worthersee. The south end of the tunnel is located at Birnbaun, on the State railroad, in the valley of Wurzener Saye. The construction of the tunnel was started at both ends and met in the center at a height of 630 meters above sea level. The fall to the south was 6%, while the grade on the north was 3%. In the construction of the tunnel there were 1700 workmen at the northern end, 1100 of whom worked in the tunnel itself, while on the south side there were 2200 workmen, 1200 working in the tunnel, which was constructed with a minimum height of 3 meters and a minimum width of 2½ meters.

The necessary power is supplied by an electrical power transmission plant, installed in Rothweinbach, a distance of 6 miles from the south tunnel portal, and another at Rosenbach, a distance of 1½ mile from the northern tunnel portal. The line voltage is 5000. The water power available at Roweinbach was equivalent to 900 H. P., with a fall of 28.4 meters and a discharge rate of 3 cubic meters per second. The power house at Rothweinbach was equipped with three turbines of 450 H. P. each, a three-phase alternator of 400 kilowatts capacity being directly coupled to each turbine, the speed being 750 revolutions per minute. Two of these three electrical generators were usually employed, the third being held in reserve. These machines supplied three-phase currents, with a frequency of 50 periods per second and a pressure of 5500 volts. The turbine wheels at the plant are equipped with automatic regulators, which control the speed very accurately. The switchboard consists of three marble panels for the measuring instruments, regulating apparatus and switches, which control the high-tension, three-phase transmission line, which connects the power house with the tunnel entrance. Highly insulated, iron-armored cables are used within the tunnel.

This power house was extremely difficult to construct, on account of the trouble of transporting the building material and machines to the site of the plant, and a new bridge had to be constructed for aiding in the work of transportation. The hydraulic installation was undertaken by Madile & Co. of Klagenurt, the mechanical equipment being installed by the Maschinenfabrik Andrits Aktiengesellschaft of Andritz, and the electrical equipment by Siemens & Halske of Vienna. The power transmission line consisted of three bare copper wires, each 8 millimeters in diameter. The total length of the high-tension power transmission line is about 6 miles, which includes an underground section of armored high-tension cable, of the three-phase type, having a copper section of 3x50 square millimeters. The entire loss on the transmission line is from the central station to the tunnel—10%.

The Karawanken tunnel is provided with a ventilator plant, the current being received from the Rothweinbach power house, and consists of two groups, with three centrifugal ventilators in each group. Each group of three ventilators is directly coupled to a high-tension, three-phase a. c. motor of 180 H. P. At a speed of 1450 revolutions a minute the ventilators supply 350 cubic meters per minute to the tunnel, making the atmosphere therein satisfactory for the workmen. These motors may be operated with short circuited windings and also with slip rings and brushes.

Each of the two motors with its group of three ventilators is operated for three days of twenty-four hours each, and at times for a longer period, after which the second group is placed in circuit while the first group is inspected. The ventilating pipe is 600 millimeters in diameter, a water-cooling system being provided, so that the air forced into the tunnel in summer is of a moderate temperature.

For this tunnel, Siemens & Halske supplied the railway locomotives. These electric locomotives were required to handle ten loaded cars of material, each 4200 kg., or together, 42,000 kg., the smallest curve having a radius of 75 meters. Or they are required to handle a train of fifteen empty cars, each weighing 1.2 ton, or together 18 ton, with the same minimum curve. The maximum drawbar pull of the locomotive is 2900 kilograms. Two of these electric locomotives are coupled together, forming a double locomotive with single control. Each axle is connected to a direct-current railway motor of 25 H. P. capacity. The normal speed of these locomotives is 10 kilometers per hour. Three of the double electric locomotives were operated on the south side of the tunnel, the total length of the trips being 7½ kilometers.

The current for operating the electric locomotives was supplied from a sub-station which was connected with the Rothweinbach power station transmission line and equipped with step-down transformers and a 250-kilowatt rotary converter. The sub-station received current from the transmission line at 5000 volts, and two stationary step-down transformers of 230 kilowatts each were provided for lowering the pressure to 350 volts, which the rotary raised to 560 volts direct current. The rotary converter has eight poles, and operates at a speed of 750 revolutions per minute. It is provided with a six-pole synchronous motor of small size for driving the rotary up to synchronizing speed.

The electric railway overhead working line consists of a bare copper wire of 80 millimeters cross section. The loss of pressure was about 10% at the greatest distance from the sub-station.

Twenty-six arc lamps of 1500 candle power each supply the outside lighting, while the inside lighting is provided by 618 incandescent lamps of 16 candle power each. The lighting current is supplied from transformers of 60 kilowatts capacity, the pressure being 190 volts for the arc lamps and 110 volts for the incandescent lamps.

There is also supplied from the Rothweinbach central power station the current for operating the two electrically driven compressors, each requiring 200 H. P., and has a workshop in the same building, the total power used being 438 H. P. The air compressors each supply 25 cubic meters of air per minute at a pressure of seven atmospheres, for operating the six pneumatic boring machines. The ventilating plant and the power station, as well as other points, are connected with a telephone system, the conductors used being 1½ millimeter in diameter and mounted on the high-pressure transmission line poles, two meters below the power conductors. The total length of the telephone conductors is 40,000 meters.

The power station on the north side of the Karawanken tunnel, located at Rosenbach, takes water from the Drau river, a small stream which supplies a minimum of 600 liters per second and a normal supply of 1000 liters of water per second under a head of 72 meters. The water pipe is of wrought iron 800 millimeters in diameter and 1850 millimeters long. This plant is supplied with three turbines of 3 H. P. each, operating at a speed of 500 revolutions per minute, with a water consumption of 510 liters per second under a head of 58 meters. Each of these turbines is directly coupled to a three-phase alternator, constructed by the Oesterreichischen Schuckert Werke, with a capacity of 270 kilowatts as a maximum load, or an output of 216 kilowatts, with a power factor of eight-tenths and a pressure of 5200 volts. This central station is connected by a transmission line 2300 meters long to the electric ventilator plant at the north tunnel entrance. This transmission line consists of three bare copper wires, each five millimeters in diameter mounted upon high-tension insulators on wooden poles. This ventilator plant includes two three-phase motors of 180 H. P. capacity, constructed by the Oesterreicheischen Schuckert Werke, directly coupled to two groups of three ventilators each, similar to those on the south side of the tunnel, supplying 350 cubic meters of air when operating at a speed of 1450 revolutions per minute. The double electric locomotive and electric railway equipment, as well as the lighting installation and telephone systems, at this side of the tunnel are very similar to those of the south side.

The use of electric boring machines is an interesting feature connected with the construction of the Karawanken tunnel. These boring tools are each provided with 2 H. P. motors operating the drills. The electric boring machines consist of a car provided with a cable drum and several electric drills mounted on an adjustable frame. Both direct current and alternating current motors have been utilized in the operation of these machines.

The current from the high-tension power transmission line, which is a 5000 volt three-phase current, is conducted through a three conductor, iron-armored high-tension cable of 3x6 square millimeters copper cross section to a transformer of 25 kilowatts capacity, which is used for transforming the pressure to 250 volts. The low-pressure cables are also iron-armored and lead-covered, with three conductors each of 35 square millimeters cross section. These cables connect with the boring machines, which are provided with drums holding about 200 feet of cable.

IT is generally acknowledged by those competent to judge of such matters that sulphides are deposited in veins and zones of fracture from ascending solutions containing them. It is also thought that under certain conditions in the upper portion of veins that these sulphides may be oxidized to sulphates and reprecipitated as sulphides numerous times, but the original source of the sulphur appears to have been the deep-seated sulphides of the original crystallized rocks and of magmas.

Placer Mining in Alaska.*

NUMBER X.

SLUICES AND GOLD-SAVING APPLIANCES, EXCLUDING HYDRAULIC OPERATIONS. — Creek miners in the Klondike and Alaska placer fields have met, with extraordinary vigor and a considerable amount of success, the peculiarly difficult conditions attendant on mining operations in the Northwest. Inventive genius has been called largely into play, since, except in parts of Seward Peninsula, hydraulic mining in working the creek deposits is not practiced. It is evident, however, to one who visits the Klondike district that the methods there in vogue for working the rich creek deposits have been developed with special attention to the economical mining and conveying of the material to the sluice, while the washing of the gravel in the sluice is not, as a rule, conducted with a view to the saving of the greatest economic amount of the gold. Whereas in the hydraulic-sluicing methods the benefit of long experience has resulted in generally commendable practice, the smaller hand and mechanical creek operations frequently exhibit gross carelessness in the matter of gold-saving appliances.

The method of shoveling by hand into a string of sluice boxes is naturally the one first tried by the miner in a remote district, working in shallow ground, after he has passed the panning and rocking stage. In these operations the cost, even under present northern conditions, varies from $1.25 to $2 50 per cubic yard (averaging $1.63), the capacity per man per shift averaging 5½ cubic yards. The most primitive appliances are the most economical. From three to six boxes, 12 or 14 inches in width by 12 inches deep by 12 feet long, on a grade of 6 or 7 inches to the box length, fitted with 6-foot 3-inch pole riffles made of saplings, form the customary rig in the interior where timber is at hand. From 30 to 60 miner's inches of water are used. Operations of this kind, where from three to twenty men shovel in, are to be found on all the gold-bearing creeks exploited in Alaska, though in the Klondike they have been largely supplemented by methods employing less hand labor. As none but rich gravel can be so worked, exigency permits a loss of fine gold. It is rare that placer miners will admit that they are losing gold; but it is safe to estimate that in the interior, where two to five boxes are in use for saving, and where drop-offs are not used, or are only such as are caused by the telescope connection of the boxes, from 10% to 20% of the gold lifted into the boxes is allowed to return to the creek bed.

It would seem that heavy losses would occur in connection with the sluicing of the winter dumps taken out in drifting operations. The strings of sluice boxes are erected at as small an elevation as possible, in order that the greater proportion of the material will not have to be rehandled when the spring sluicing is done. Boards are laid over the sluices, and when sluicing is resumed the water is turned through the sluice, and, beginning at the lower end, the boards are successively removed. As much of the gravel as possible is caved in, sometimes with the assistance of a nozzle, and the remainder is shoveled, wheeled to and dumped into the sluice. Small bunkers or hoppers are sometimes built over the sluices; but no hoppers of large capacity, like those in use in Plumas county, Cal., were seen in the north. On Anvil creek, in Seward Peninsula, a large winter dump was handled in this way, with the exception that those portions which could not be caved to the sluices were conveyed to it and dumped in by means of horse scrapers. Though loss of gold may be permissible in primitive operations of small capacity, it should become proportionally less when larger mechanical installations are made and the capacity of the plant is increased.

One of the early difficulties which the miner in the interior encountered was the presence of sticky clay and mud in the rich pay dirt. The difficulty was partly overcome by the introduction of the mud box, or puddling box, which was set in the middle or at the upper end of the string. Into this the men shoveled, or a bucket or car dumped. Fig. 17 shows the form of the mud box used in the Klondike and its position in the line of boxes. Its grade is generally made steeper than that of the rest of the string; 12 inches is common. The services of an extra man as stirrer, who also forks out the large stones, are required.

Where men shovel into boxes, the mud box is used merely as a wide part of the sluice. In larger plants, where buckets, cars or derrick skips dump into the mud box, a platform, inclined at an angle of about 50°, 9 feet square, and built up of timber floored with rough scantling, is erected on the side of the box for the gravel to fall on.

Typical Scene in Placer Mines—A String of Sluices Showing Mud Box.

The capacity of the sluice is cut down rather than increased by the use of the mud box, and the expense is increased by the cost of the man. A greater saving of gold is made; but at best the operation is expensive and of small and variable efficiency. In some shoveling-in operations the use of the mud box is advisable; but where mechanical self-dumping buckets are used, it is possible that some other form of agitator might be advantageously employed.

The developments of the open-cut and drifting methods of gravel mining have necessitated an enlarging of the sluicing capacity. With the enlarging of the capacity, however, there has not been a proportionate improvement in the construction of the gold-saving appliances. In other words, instead of drawing on the experience of the hydraulic miner and the dredger miner for the adoption of gold-saving methods, the creek miners of the Klondike have continued the method of the long, narrow sluice used for shoveling-in operations, amplifying its error and suffering the inevitable losses of fine gold which its use entails.

The average capacity of a small placer operation where hand labor is employed is 40 cubic yards in a day of ten hours. Grant that the narrow sluice of 36 feet in length with pole riffles is most economical for the needs of such a man. Now take an average summer drifting plant, where the gravel is dumped into the mud box by means of the cable tram and self-dumping carrier. The capacity is 175 cubic yards in twenty-four hours and the cost is approximately $1.50 per yard. After it is hoisted from the shaft the material is elevated to a height of 25 feet above the surface of the ground. Water is pumped to this height for sluicing. The sluice consists of a mud box 16 feet long and 30 inches wide, on a 12-inch grade, tapering to the 14-inch sluice boxes which follow. There are eight of these, set on a grade of 10 inches to 12 feet, furnished with pole riffles, which last three weeks only and cost $3 per box length to renew. The man forking in the mud box costs $6.50 a day of ten hours. At this plant the gold is in part very finely divided, and it is impossible to believe that the sluice in use is operating with economy.

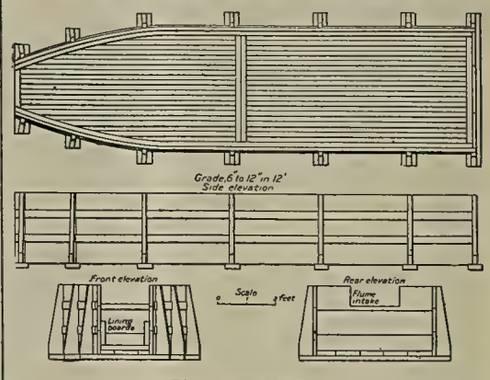


Fig. 17.—Mud Box.

Proof of the losses now going on in the Klondike was seen on a neighboring creek. At a plant somewhat larger than the one above described, where 240 cubic yards a day were handled at a cost of $1 a cubic yard, a small undercurrent had been installed at the end of ten 16-inch boxes, 12-inch grade, pole riffles. The undercurrent was fed through a small iron grizzly and consisted merely of one 16-inch sluice box, 12 feet in length, with a riffle of cocoa matting and expanded metal. It cost $20 to construct this device, which was saving an average of 5% of the product each day. A sample of the gold was taken, and although some of it is too fine for handling, such particles as could be weighed and counted gave a result of 280 colors to the cent, the gold being worth $15.60 per ounce. Gold of finely divided but never flaky character was seen in all the large producing creeks of the Klondike, and at the new Fairbanks district of Alaska.

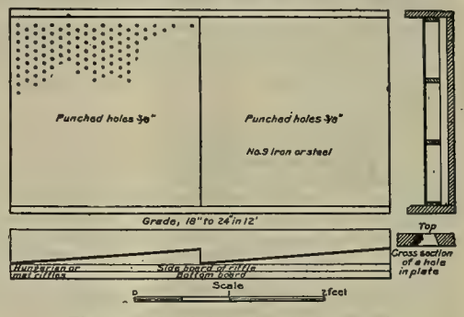

Fig. 18.—Modified Caribou Undercurrent.

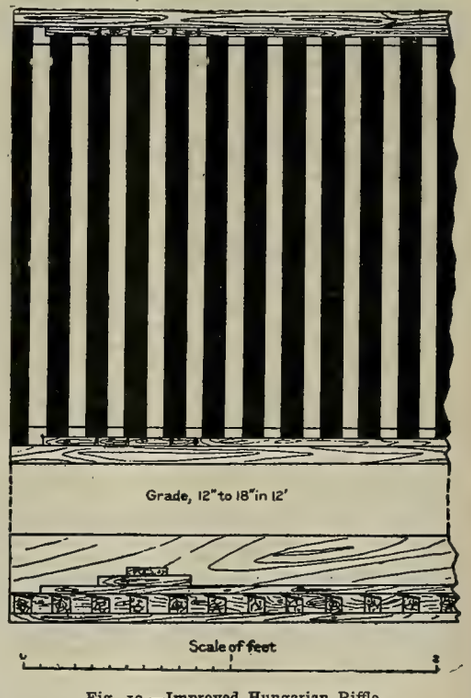

Fig. 19.—Improved Hungarian Riffle.

The plants above referred to represent the average capacity of the creek mines of the interior of Alaska,

*Bulletin 263 U. S. Geological Survey.

where the hoisting of material and frequently the pumping of sluice water are necessary. It costs from $3000 to $5000 to rig up such plants, which are used for three seasons or longer. To install a washing plant in such a case as the above would add little to the first cost, and the additional expense would probably be justified by the results.

Before entering on suggestions as to the use of washing plants, I wish to emphasize the fact that the methods of sluicing in use in Alaska, especially in the Birch Creek, Forty-mile and Fairbanks districts, and, to a certain extent, in Seward Peninsula, have been and will continue to be influenced by the Klondike developments. Though many of the methods developed in the Klondike are excellent and are worthy of imitation in any country where conditions are similar, at the same time the Alaskan miners should note the wrong principle of the primitive sluice box which has been continued there. The entire absence of screening or use of grizzlies, other than the rough, expensive hand method employed, renders valueless much ground which could be worked. A plant costing $5000, designed to thaw, excavate, hoist, convey and wash 150 cubic yards a day at a cost of $1 a yard, could by an addition of from $500 to $2000 to the first cost of the plant and an addition of 10 cents per yard to the cost of washing, recover at least 10% more value in gold from a cubic yard of material.

It may be said that the fine gold found in the Klondike does not occur in the Alaska creeks. This is disproved by experiments made on small parcels taken from pannings on the various creeks. Fine gold from Fairbanks creek, in the Tanana district, runs 500 colors to the cent, the gold being worth $17.70 an ounce. A small proportion of gold from Ophir creek, in Seward Peninsula, was found to run 170 colors to the cent, the gold being worth $18.50 an ounce. No means of knowing the proportionate amount of this gold is possible, as with the methods at present employed very little of it is recovered. Five per cent is considered a fair average of the total gold represented by the above fineness of division. This gold, which is not flaky in spite of its fine character, could easily be saved with the proper appliances, and there is no doubt that much coarser gold is lost.

The question will be asked: Can a cheap and efficient washing plant be installed, where gravel must be elevated by power, which will not add greatly to the cost, and the parts of which can be easily and quickly made with the materials at hand?

On the principle that gold is best saved in the thinnest sheet of water which will carry the tailings away, it is evident that for fine gravel a wide sluice is better than a narrow one. In the narrow sluice boxes, full or nearly full of running water with great velocity, fine gold will be carried along. Lengthening the sluice will not help matters. In fact, a short sluice with drops or undercurrent attachment is frequently more effective than a long sluice without it.

In a given case assume that the ordinary 14-inch boxes are widened to 24 inches, and that five boxes with a grade of 9 inches to the box, fitted with the ordinary sapling-pole riffles, as at present, are succeeded by three boxes with the form of screen represented in Fig. 18, the grade being made adjustable by means of blocking. An addition of 19½ inches to each of the three boxes would compensate for the loss of grade consequent on the uptilting of the screens. The whole drop in the string of boxes would be 103.5 inches, as against 108 inches were twelve boxes used with a 9-inch grade. Under the punched iron plates riffles of one or more kinds, as described below, charged with quicksilver, should be used. The riffle shown in Fig. 19 will be found satisfactory. Mats, plush or blankets may under certain conditions be found more economical. A short transverse table following the last box, arranged under a grizzly from which the large material is discharged to the dump, will enable the operator to determine whether losses are occurring in the main sluice and screening boxes.

The above installation is in principle a series of undercurrents combined in the main sluice. Its advantages of cheapness, adaptability to conditions and simplicity recommend it. No extra power or water is required. On the other hand, the use of the mud box is not obviated.

(TO BE CONTINUED.)

The Pioneers of the Desert.

The desert of southern Nevada continues to attract much attention from the mining world generally by reason of the repeated announcement of rich strikes in districts both old and new. The discovery at Tonopah by Butler five years ago has been like a pebble dropped in the mill pond—the waves have radiated outward from the center for miles in every direction—and numerous discoveries have been made as the direct result of the impetus which Tonopah gave to mining in the Great Basin.

Old districts, practically abandoned for years, have again come into prominence, and in the unknown territory lying between these old-time camps new districts have been founded and towns have grown up there almost in a day. As a matter of course, no ordinary mine can long exist in that region, remote from the source of all supplies—nothing but the high-grade mine survives. The freighter found profitable employment at first in hauling the rich ore from Tonopah to the railroad. As the prospectors pushed out, Lone Mountain, Gold Mountain and then Goldfield came into prominence. Later Bullfrog and Kawich made demands on the teamster and his outfit of wagons and mules.

The railroad has penetrated to Tonopah and Goldfield, but there still remain other outlying districts; so that the freighter is not without occupation, nor is he likely to be for a long time to come in that section.

The accompanying illustration is typical of a desert ore-hauling outfit, such as may be seen now any day on the sage-covered plains and hills of southern Nevada. The summer season has drawn to a close in that region, and with it the most menacing of the dangers which beset the prospector on the desert. Water is not more abundant, generally speaking; but both days and nights are cooler now and the risks are noticeably lessened. This means a revival of active search for new bonanzas, and the prospectors are already setting out in quest of new districts—north, south, east and west from each of the several centers of supply that have been established within the past four or five years—and it is safe to predict that the coming fall and winter season will see new and, at this time, unheard of camps spring into existence, and in these will be re-enacted the scenes so familiar in the older camps. The entire populace of that region is on the qui vive and ever ready at the first announcement of a new strike to swoop down upon the district almost en masse. A few are successful; the remainder linger disappointedly about, waiting no less eagerly for the next stampede, confident that luck will favor them at the next turn of fortune's wheel. It is this feeling of optimism that aids largely in sustaining these new camps, where there is little comfort in human existence; but it is the nature of the prospector—he is "built that way"—and to him and his brother, the freighter, is due almost entirely the tremendous development of that desert region known as the Great Basin.

Hauling Ore From Surface Workings at Goldfield, Nevada.

A COAL HOISTING FEAT was performed at the Maxwell No. 20 shaft, in Luzerne county, Pa., a few days ago, says the American Manufacturer. Because of a scarcity of cars the full capacity of this breaker had never been tested. But last week there seemed to be no limit to the supply of cars, and in nine hours 1285 were hoisted—an accomplishment considered remarkable in a district where mining machinery is thought to have reached its greatest development.

History of Pyritic Smelting.*

NUMBER II.

By ROBERT C. STICHT.

In 1878 John Hollway took steps to test by actual experiment his expectations on the subject, and made a decisive attempt to apply the principle of rapid oxidation to pyritic ores. For a beginning he had the great advantage, over the past, of the important theoretical aids now offered by thermochemistry, and by consulting their testimony before embarking on experiments on a large scale he marked, more clearly than by any other undertaking, the immense strides by which the science of metallurgy had advanced, chiefly in the preceding three-quarters of a century.

But the thing was to put the idea to practical test. This followed in due course, first on a small scale, and then with the aid of the full complement of the colossal plant of the steel works, in all cases with equally significant success, fully substantiating the pre-established theoretical results. In the spring of 1878 Mr. Hollway began by forcing a current of oxygen gas through molten iron sulphide in a clay crucible. Then air was blown through cupriferous iron pyrites that had been previously melted in a steel melting furnace, larger crucibles being employed and a proportion of sand added, in order to flux the protoxide of iron. This test lasted half an hour. Like the preceding one, it demonstrated that sufficient heat was actually developed by the iron and sulphur to keep the mass in a molten condition. A fluid slag was formed, and the copper was concentrated in a small body of enriched regulus, which separated readily from the slag. In other words, it was, so far, conclusively proved that pyrites could be melted by the heat generated in its own oxidation. It was evident that, if iron pyrites could be made to behave in this manner at all, there was reasonable indication that the operation might be carried on in a proper furnace, notwithstanding the fact that the trials were made on pre-molten ore and the furnace would have to take it cold and raw.

However, the small tests revealed a feature which the thermal calculations had been silent on, and that was the insufficiency of a low blast to achieve the best effect, and the necessity of a fairly rapid oxidation. This observation caused the selection of the Bessemer converter as the most accessible and only immediately available apparatus guaranteeing the required pneumatic advantages. Thanks to the assistance of Mr. Matheson, Mr. Hollway was enabled to conduct a systematic series of trials at the Penistone steel works of Messrs. Cammell & Co., near Sheffield, in July, 1878, and subsequently, all of which fully confirmed what yet was wanting demonstration. Mr. Hollway at once expressed his opinion that the Bessemer converter was not a truly suitable apparatus for the work, but, of course, inferences from the behavior of the substances within it could be reliably applied to other apparatus capable of exciting the same energy, which was wholly within the capabilities of the blast furnace of that time.

The material used for these larger experiments was ordinary Rio Tinto pyrites, with about 3.5% copper. It was run down with coke in the pig iron cupola and conveyed into an ordinary 6-ton, gannister-lined steel converter, served by the usual blowing engines, supplying a pressure of 20 pounds. The first blow was made on the 10th and 11th of July, 1878, and lasted half an hour. No sand having been added, the lining was greatly corroded. The second trial was made on the 11th and 12th of July, the regulus obtained after fifteen minutes of blowing showing an increase of copper of from 3.4% to 46%. Sand having been thrown in, the corrosion decreased cor-

*Abstract of Proceedings Australasian Inst. Mining Engineers.

respondingly. Six experiments were made, consecutively, on the 17th and 18th of July, and every metallurgical detail observed, the gases sampled, their temperatures measured, and the spectroscope applied. The six tests all gave similar results.

Mr. Hollway at once followed to their utmost theoretical limits all the possibilities of the process, and laid them before the Society of Arts at a meeting held on the 12th of February, 1879, Prof. Roscoe presiding. Together with the discussion, this article forms one of the most interesting contributions to the archives of the science of metallurgy, just as the magnificently successful experiments themselves constituted one of the most daring and conclusive events in the annals of the art. The simple chemistry of the process is quite fully discussed, and its principles and their corollaries clearly enunciated, and, in fact, that paper, with the critiques of the members, may be regarded as a small pyrite smelter's gospel, voicing early inspirations.

In 1880 F. Manhes began his experiments for blowing mattes up to white metal in one operation, in a regular Bessemer converter, suitably modified, at Vedennes and Eguilles, near Avignon, in France—a scheme which was subsequently perfected by being extended to the black copper stage, and which has become the beautiful process which nowadays is so widely in favor. It belongs to exactly the same metallurgical family as pyritic ore treatment, and is the most fitting supplement to the preparatory work done by the latter, where the ores are suitable. Yet, with the usual subversion of natural sequence characteristic of historical development, it reached its climax first.

The agglutination of the ore column in the upper portions of the furnace shaft by the volatile sulphur, and the consequent hanging of the charge, even when the hearth region showed signs of smelting, was the obstacle encountered at the very beginning of all trials with heavy sulphides. Hot blast might have led to success in such cases, but works treating basic ores did not have this attachment, and those that had it were working siliceous ores, which lacked the pyrites.

Apparently almost no records of such attempts have found their way into literature. One instance, however, may be cited, as probably typical of others, or all. It is the experience of C. A. Hering, who, no doubt, induced thereto by the Hollway experiments, tested the pyritic idea in 1878 at Accessa, in Tuscany. Before tempting the Providence that controls the behavior of blast furnaces, Mr. Hering turned a large roast heap into an exaggerated wind smelting pile, such as the more primitive nations of the middle ages were in the habit of obtaining their lead with. A larger bed of wood was given than usual, the heap built up higher than ordinary, the sides thickly covered with roasted fines, and an updraught through the pile provided. After ignition a great evolution of heat took place, with a sulphur flame at the apex of the pile, which lasted for days, while molten regulus in quantity ran from the base. In three weeks the heap was opened. At the bottom it showed a tremendous sow; above that a conglomeration of ore, matte and slag; over that, well-roasted ore, and on top, the residues from the liquation of the sulphide ores, chiefly consisting of quartz. Some of the latter showed unmistakable signs of fusion, without having been fluxed, so that the temperature evolved must have been enormous. Mr. Hering's next attempt was in the blast furnace at the same place in 1879, the declared intention being to make a richer matte while saving coke. As the plant did not permit of special alterations for the purpose of the best effect, the investigation had to be limited to giving more blast than usual, and later on a higher pressure. The improvement was undeniable. Ordinarily the sulphur loss within the furnace was 11%; it was now 15%. The matte usually contained 23% to 24% copper, but now ran 28%. These small advantages, however, seemed to the experimenter outweighed by certain more serious disadvantages, such as overfire, irregular sinking of the charges, increased flue dust, the dragging of more or less matte into the slag pots, and a worse separation. Consequently no further trials were made.

The pure form of pyrite smelting, as well as partial pyrite smelting, thus lay dormant from 1880 on, and pyritic smelting also seemed to be on the wane. They required renewals of impetus towards further progress which, practically, only those conditions of ore supply and mineralogical character of the same could give, which were sufficiently one-sided to be amenable to no other smelting methods.

F. A. Bartlett is the pioneer of pyritic smelting in America, and during the eighties devoted all his energies to its cause. His operations were conducted in the State of Maine, but his advocacy of the process covered the entire country. He rightly considered it a lost or forgotten art, though filling a most important place in the metallurgical rank and file of methods, even when locally dissociated from the subsequent extraction of the precious metals from the mere middle product, i. e., matte, which is all that it can produce. Mr. Bartlett's opinions on the method resolved themselves into a matte smelting of the raw ores in a very simple blast furnace plant, practically independently of all but the merest traces of copper. In this metal he empirically drew the line at 3% on the charge. He obtained mattes as high as 70 to 80 ounces of silver per ton with both lead and copper absent—i. e., making excessively siliceous slags containing less than 1 ounce of silver—but with ½% copper on the charge he rose to 200 ounces of silver in the matte, and with 3% copper up to 700 ounces, without serious losses. The ores he considered most suitable were those carrying considerable amounts of iron and manganese, and the sulphur contents were to be regulated by partial roasting, when high, and the use of sulphides raw, when low. The advantage of a possible partial desulphurization in the furnace itself came in as a very largely recognized feature also, but was not made the paramount feature. Coke was still used in considerable amount, and only a reducing furnace atmosphere contemplated. Blast pressures were as yet low—i. e., from 8 to 12 ounces per square inch—and furnaces were small. Mr. Bartlett's type of 1887 measured 3 feet by 4 feet at the tuyeres, of which there were eight, and about 8 feet from tuyeres to charge opening. This furnace was water-jacketed all over, except the drop bottom, and used a heated blast derived from the furnace gases by means of an air-jacketed hood above the throat. The blast was trapped for the slag outlet, but there was a special tap for the matte, direct from the furnace hearth. The constructional departures from the European types thus briefly indicated marked the radically different circumstances under which pyritic smelting now had to be made successful, and also indicate the general trend of the improvements to be effected in the wake of the migration into transatlantic surroundings. The utility of a large blast volume was understood, and fans were advocated by H. M. Howe and others, but rotary blowers were ordinarily employed.

We now finally enter upon the period, and into the circumstances, in which the most interesting division of the general subject—viz., the special one of pyrite smelting — suffered a restoration. This revival occurred in the United States of America, in the western part of the country, in the Territory of Montana.

In the latter half of the eighties an English company, originally engaged in, or an offshoot from one engaged in, the pastoral industry on the high plateaux of Montana, founded a township on the banks of the Missouri river, in a promising agricultural valley, about 40 miles east of Helena, the capital of the Territory. The inducement to locate there was the presence of a few mines, and that of the Northern Pacific Railroad, which ran alongside the river at the point selected. The township was called Toston. The original industry having proved disastrous, owing to the long and very severe winters, it may have been proposed to try smelting instead. Any way, a small plant was erected for the purpose, but not much hope of success attended the enterprise until it was decided to utilize the gold-bearing iron pyrites of certain adjacent mining properties, which gave some promise of permanency. The metallurgical affairs were in the hands of W. L. Austin, and to him is due, not alone the second—or Western—rejuvenation of pyritic smelting in America, but also a later, still more excellent, because more difficult, achievement—namely, the consummation of pyrite smelting, as we now know it, in blast furnaces. Mr. Austin's attainments as a Freiberg graduate and erudite metallurgist easily found the only direction in which the local ores could be made amenable to profits, and first suggested the application of the old Roharbeit or pyritic smelting. In 1885 a small, old-fashioned sandstone furnace, about 4 feet square inside, and provided with water tuyeres, was erected for this purpose. Experiments showed that the German spurofen style of hearth construction was the most suitable, the products discharging continuously through a taphole, without trapping the blast. A Herreshoff furnace was also employed, but proved inconvenient, on account of the inaccessibility of the passage leading from furnace to forehearth, which the irony matte constantly choked up. At first, as in the Roharbeit days, the ore was not roasted, but the matte subjected to this operation, and resmelted with siliceous ores to enrich it. Lead soaking, etc., were not carried out, but the product sold to large lead smelting works elsewhere. The most satisfactory results are said to have been obtained with a low column and large volume of air, coke being used for fuel in due quantity. The pyrites in the mines became granular after a while, and finally so fine that one-half of it had to be roasted in a calcining furnace and bricked with lime. No lead or copper ores were bought, but some copper must have been present, however little, for the recoveries clashed with the well-known fact, established through centuries of similar work, that pure iron matte is not a suitable collector for gold and silver. About this time special research by E. G. Spilsbury and others had definitely settled this point, at least as far as gold is concerned. As a matter of fact, too, the mattes subsequently obtained out of the main ore by means of pyrite smelting did contain considerable copper, although it was lost sight of, because not paid for by the purchasers. The undertaking up to this stage seemed but little destined to make a name for itself, for ore was scarce in the immediate vicinity, and not to be had elsewhere except by means of a railway journey of a couple of hundred miles, and coke was very dear.

This precarious and stressful condition of affairs is directly responsible for the revival of the blast furnace bessemerizing of sulphide ores, which had been abandoned by Mr. Hollway, and which, under Mr. Austin's direction, was here to be achieved in a diametrically opposed environment. The former had at his command all the tremendous paraphernalia of the iron industry, the latter only the most limited array of commonplace apparatus, sufficing for matte smelting on a very small scale. Nothing could appear less promising, for it must have seemed that if pyrite smelting was capable of balking even the most intense metallurgical energies which could be brought to bear on it, then the resources available at the poverty stricken Toston smelter had not a shadow of hope of success. However, the outcome was the very reverse. Still, success was not born in a moment, but came by slow degrees.

It was natural, since coke was dear and funds were scarce, that a Freiberg student should revert to hot blast, which could be fired by wood or coal, in order to cut down the consumption of the dearer fuel. Accordingly Mr. Austin erected a small impromptu iron pipe stove, of cramped dimensions. This had, one may assume, all the desired effect, when not out of order. A Root blower permitted of pressures of blast up to 3 pounds in the small furnace.

Now undoubtedly followed a series of observations which, in due course, guided Mr. Austin to the bold step of depressing the coke percentage to less than half the usual amount, with the deliberate object of forcing the fuel qualities of the iron pyrite to assert themselves as an essential contribution to the heat balance of the furnace. In any case, what had not been dared, or, if dared, had not been successfully carried out before, anywhere else, was to be accomplished with the confined and shabby appointments of Toston. Many desultory runs were made, and the process tested as far as possible, although the course of experimenting was made particularly rough by a variety of circumstances, technical and otherwise.

Meanwhile financial stress, scarcity of ore and internecine troubles caused the cessation of smelting operations, and the plant was shut down. For some time it was leased as an auxiliary plant by the Helena M. & R. Co. for the treatment of Cœur d'Alene galena ores, and a 36x78-inch lead furnace, of the usual American water-jacketed type, was erected by the lessees. Upon the termination of the lease this furnace afforded the Toston company a more adequate opportunity for further testing the pyrite work, and, when operations were finally again resumed after finances had been improved, this furnace was altered to suit matting operations. A much more appropriate cast iron pipe stove, of the hanging U-tube pattern, of fair dimensions, was also constructed. In 1890–91 the experiments were resumed on the enlarged scale now possible, but, for various mechanical reasons, which it is unnecessary to detail, the work was not successful as a continuous exhibition of the possibilities of pyrite smelting. There was, of course, the same dearth of proper ores as before, and much rubbish had to be treated. Special precautions were taken to meet special troubles that presented themselves. For instance, the jackets of the narrow lower tier, resting immediately on the bottom plate, were made solid, in order to resist the dynamiting which was resorted to for the purpose of rending the accretions that accumulated in the hearth—this operation being a portion of the regular curriculum of the campaigns. However, sufficient information as to the proper furnace mixtures, etc., was gained to allow of successful exhibition smeltings whenever special occasions required them to show off the process. Mr. Austin went to Colorado in 1891 to introduce the process there, and the patent was granted soon after, in the same year.

On the strength of the latter a new company, operating the Toston plant, was formed, which controlled the rights for the two States of Montana and Idaho. Although a practical superintendent, possessing the whole fund of collective experience at the place, was in charge, it was felt that outside judgment was desirable, and accordingly the writer investigated the Toston innovation in the fall of 1891 for some friends. The aims of the process were being much misunderstood, and its products even placed under a ban, inasmuch as one lead smelting plant, which had purchased the matte, attributed heavy losses in gold, which it had sustained, to the Toston manufactured material. A banker, a man of sagacity, however, was accustomed to declare that if the furnace could be made to run for a day he could not see why it could not be persuaded to run for weeks. The opinion is certainly justified that, had it not been for the common sense, patience and faith of this interested though wholly untechnical gentleman, the art of pyrite smelting would once more have suffered a relapse, in Montana, at least.

Of the few weeks which the writer spent at Toston as the counsellor and guide of the superintendent, it will be sufficient to say that everything went fairly smoothly. It was patent how the furnace action differed from that of the wholly coke-fed furnace, but, as the phenomena required a complete reversal of the predisposition of mind generated by the ordinary blast furnace practice, there was an abundance of novel and interesting points.

(TO BE CONTINUED.)

Disposition of Exhaust Steam From Mine Pumps.

The disposition of exhaust steam from pumping machinery in mines is a worthy subject. In mining operations large bodies of water are frequently met. A method of steam condensation is provided by the A. S. Cameron Steam Pump Works, foot of East Twenty-third street, New York, herein illustrated and described:

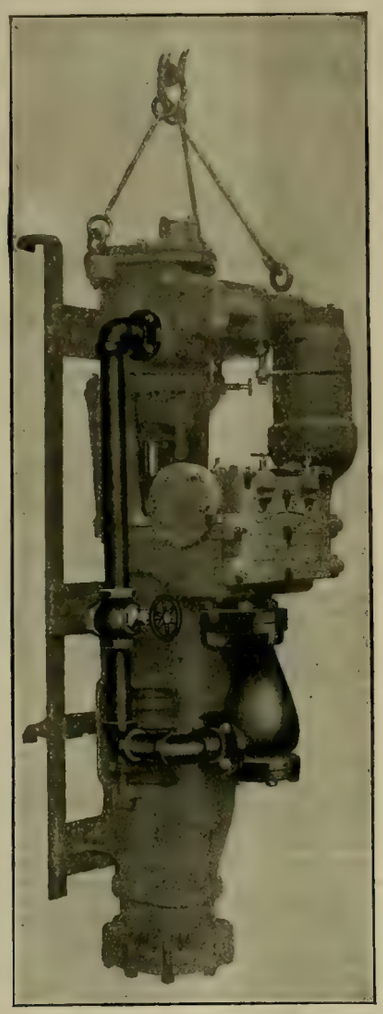

FIG. 1.

Fig. I shows a Cameron vertical plunger sinking pump, having the slings attached by which it is hung in the shaft. The darker portion shows the condenser, with the exhaust pipe leading thereto, and bolted to the water valve chest.

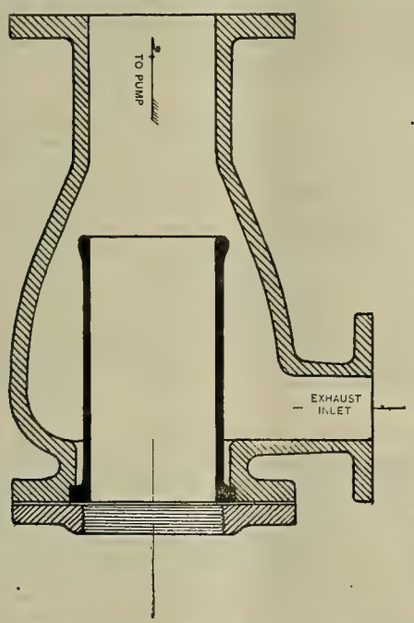

FIG. 2.

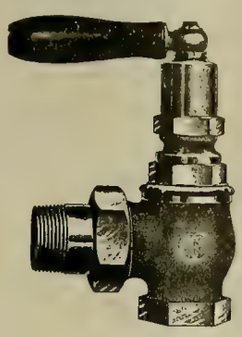
Fig. II gives a sectional view of the condenser chamber. The constant flow of water through the suction piping connected to the bottom of the condenser is designed to cool the bronze sleeve which is arranged within this chamber, so that when the exhaust steam comes in contact with the cool surface part of it will immediately be condensed and the remainder passing through the annular opening will also be condensed after mixing with the water passing through the suction. It is necessary that the water cylinder be fully charged before the exhaust steam is turned into the condenser, by allowing the pump to exhaust into the atmosphere until it has become filled with water, then the three-way valve may be turned and the exhaust steam admitted to the condenser, but it should not be allowed to enter except in combination with water. In some cases automatic floats are arranged to stop the pumps when the water supply is down. An air leak is fatal to the successful working of any condensing apparatus.

The manufacturers claim that expense and delay when the pumps are moved about in the mines can be avoided by the use of the Cameron condenser.

Self-Packing Steam Radiator Valve.

Herewith is illustrated a Crane quick opening self-packing radiator valve. The lever handle can be operated by the foot, as well as by the hand. The construction of these valves is such that, when closed, the discs bear on the seats very tightly, and the valve is locked in place until released. The bonnets of these valves are interchangeable with the bonnets of Crane regular radiator valves. These valves have artistically designed proportions and add much to the appearance of a nicely furnished apartment by their symmetrical proportions and rich appearance. Prices, etc., will be furnished by the manufacturers, Crane Co., Chicago.



Falling Bodies in Deep Shafts.

There still remain things connected with the force known as the attraction of gravitation which are difficult to understand. Theoretically, any object dropped in space above the earth falls directly toward the center of the earth. The plummet is supposed to indicate the direction in which the center of the earth lies. Notwithstanding this, it is now said that objects dropped into deep vertical shafts never reach the bottom, but always fall toward the east side of the shaft, lodging somewhere in the timbers, nothing reaching the bottom which falls into the shaft from or near the top. It is said that this peculiar fact has been demonstrated at the Red Jacket shaft of the Calumet & Hecla copper mine, near Houghton. The article, no matter what shape or size it may be, is invariably found clinging to the east side of the shaft. One day a monkey-wrench was dropped, but it did not get to the bottom. It was found lodged against the east side of the shaft several hundred feet down. This incident coming to the attention of the Michigan College of Mines, it was decided to make a careful test of the apparent phenomenon. It was decided best to use a small but heavy spherical body, and a marble tied to a thread was suspended about 12 feet below the mouth of the shaft. When the marble was absolutely still, assuring that it would drop straight down, the thread was burned through by the flame of a candle. The marble fell, but at a point 500 feet from the surface brought up against the east wall of the shaft.

The same would be the case were a man to fall into the shaft. While it would mean sure death, the body, badly torn, would be found lodged in the timbering on the east side. Members of the faculty of the College of Mines are now engaged in experiments with a view of developing data as to the thickness of the earth's crust. It is not hoped to solve the perplexing problem of the distribution of the earth's matter, but it is hoped to add to the information collected concerning it.

To this end the Red Jacket shaft presents advantages possessed by no other place in the universe. The deep shafts in other parts of the country and in foreign lands generally begin at an altitude and end above or very little below the sea level, whereas at the Calumet mine the Red Jacket shaft starts in a comparatively low altitude and pierces the earth's crust deeper and farther below the ocean level than any other in existence. It is hoped within a year to be able to give some intelligent information regarding the investigation.

It is probable that further investigation of this matter will show that the rotation of the earth on its axis is in some measure accountable for these phenomena, and that it is not wholly due, as heretofore supposed, to air currents in the shaft.

THE PROSPECTOR.

The rock sample from Glen Ellen, Cal., is andesitic breccia. The dark colored fragments are andesite and the white, chalk-like material is rhyolite tuff. This rock is very common in the volcanic regions of both the Coast Range and the Sierra of California.

The rock samples from Custer, Idaho, are: No 1, light, a much altered eruptive rock, possibly an old andesite, too much altered and kaolinized for determination. This rock resembles what was known on the Comstock, by the old geologists, as propylite, and was at one time supposed to represent a distinct class of rock, but it is now known that several rocks of that district by alteration take on the characteristics of the so-called propylite. No. 2, the dark rock, is a metamorphic sedimentary rock. It has been silicified somewhat and evidently contains carbonaceous matter.

The mineral specimens from Middletown, Lake county, Cal., are: No. 1, iron sulphide (variety marcasite); No. 2 is principally pyrrhotite, the mono-sulphide of iron, which is magnetic, but associated with it are also pyrite, chalcopyrite (copper sulphide) and cinnabar (the sulphide of mercury). The percentage of copper present is appreciable, probably 3% or 4% in the specimen. No. 2 is an unusually interesting ore, because of the various minerals it contains.

The mineral samples from Weiser, Idaho, are determined as follows: No. 1, a basic eruptive rock in the vesicles of which copper carbonate has infiltrated; No. 2, iron stained jasper; No. 3, a veinlet of crystallized quartz in an eruptive rock, much altered but apparently aplite; No. 4 is a silicified greenstone (diorite); No. 5 is a type of granite much altered and containing a little copper carbonate; No. 6 is also a granitic rock containing pyrite (iron sulphide); No. 7 is volcanic ash; No. 8 is largely magnetic iron sand. Samples of this sand should be sent to Dr. David T. Day at the Exposition in Portland, Or., for a determination of its several constituents.

The rock samples from Sheridan, Mont., are: No. 1, diorite; No. 2 is hornblende granite, much altered; No. 3 is a veinlet of quartz and feldspar, with some iron sulphide occurring in a granitic rock. The pink color is due to iron oxide, and the green color to iron silicate.

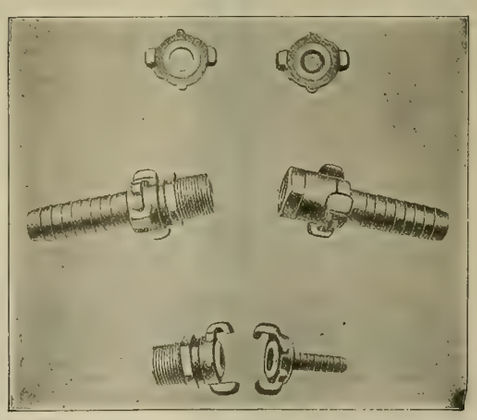
The small black pebble from Hayden Hill, Lassen county, Cal., is black obsidian, a variety of volcanic glass. It has no value.

The soft white mineral from Placerville, Cal., is infusorial earth. The diatoms observable under the microscope are of great variety and interest.

Chicago Hose Coupler.

The Chicago hose coupler is designed to meet the demand for a universal coupler, so that a plant, once standardized, could be so maintained.

The coupler illustrated herewith has no male or female part at coupling end proper, but instead each



half has embodied therein both features whereby each is the same, and will couple regardless of the size and style of the shank.

These couplers are manufactured by the Chicago Pneumatic Tool Co., Chicago, Ill.

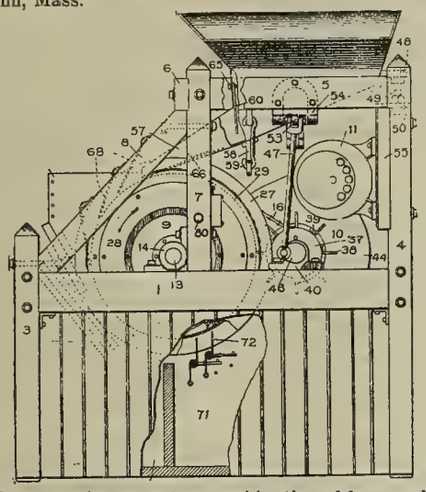
It is uncertain by what process of nature an ore consisting of definite proportions of gold, silver and tellurium, as tellurium ores, are formed. All experiments attempted with a view to produce homogeneous compounds of gold, silver and tellurium have thus far failed, though there has been no difficulty in obtaining metallic gold and tellurium salts, or mixtures of gold and tellurium in irrational composition. The sponge-like gold produced by some mines is thought to be psuedomorph after tellurium. It is not uncommon in Cripple Creek and in some parts of California where tellurides are found.

Mining and Metallurgical Patents.

PATENTS ISSUED OCTOBER 3, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

MAGNETIC SEPARATOR.—No. 800,370; C. M. Green, Lynn, Mass.

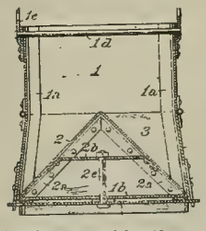


In magnetic separator, combination of frame, electro-magnet mounted thereon comprising two similar interlocking core bodies having pole pieces formed thereon and coil inclosed by core bodies, non-magnetic cover for magnet, contact devices for conveying current to magnet, hopper pivotally supported at one end, means for moving hopper to distribute material to be separated over magnet, means in hopper for breaking up masses of material, means for breaking up masses of material after leaving hopper, and revolving brush for removing magnetic material from magnet.

DEEP BORING APPARATUS.—No. 801,072; E. Frieh, Nordhausen, Germany.

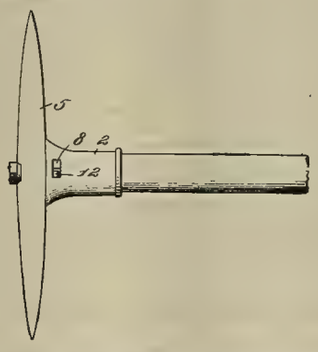
In deep boring apparatus with percussion drill and core tube, combination of boring rod, core tube rigidly secured thereto and provided with slots in lower extremity or shoe, drill driving apparatus within bore hole, and percussion drill connected with driving apparatus and provided with cutters which enter end slots in core tube.

DUMPING BUCKET.—No. 800,711; S. M. Bishop and J. L. Mitten, Wellsville, Ohio.



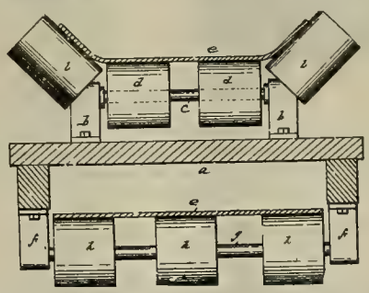
In dumping bucket, combination of quadrangular body having lower discharge opening in each of sides, pyramidal bottom, doors, each swinging outwardly opposite one of sections of bottom, and hinged to body above one of discharge openings, and means for coincidently locking and unlocking all doors.

PICK.—No. 801,166; A. Walker and R. W. Mewes, Whatcheer, Iowa.



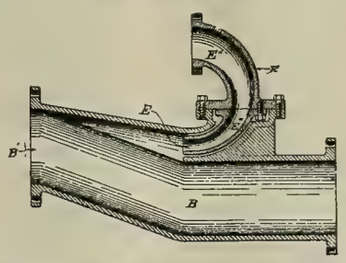
Socket having hole extending thereinto, and slots at opposite sides of hole and opening thereinto, combined with tool blade fitted against socket and having hole to register with that in socket, bolt adapted to extend through registering holes and provided with lateral fins to enter slots when bolt is turned, and nut threaded on to upper end of bolt and adapted to engage outer face of tool blade.

BELT CONVEYOR MECHANISM.—No. 800,786; W. E. Bee, Detroit, Mich.



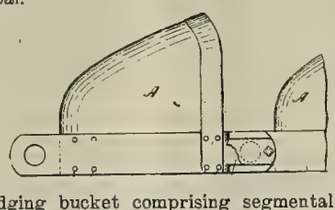
Conveyor belt roller, having in combination therewith upwardly projecting oil case forming interior oil chamber open at upper end and provided with spindle projecting upward through oil chamber, roller constructed with sleeve or hub engaged upon spindle, oil chamber arranged to contain supply of oil to submerge lower extremities of spindle and of hub.

HYDRAULIC ELEVATOR FOR DREDGING PURPOSES.—No. 800,910; B. Flood, Los Angeles, Cal.



In hydraulic elevator, means to introduce water under pressure between elevator pipe and suction pipe, comprising return bend E made up of upper and lower member E″ and E‴, respectively, secured to connecting branch B and together as shown.

DREDGER BUCKET.—No. 800,936; T. O'Leary, Oakland, Cal.



Dredging bucket comprising segmental rim with digging lip at front, longitudinally disposed extension from opposite side of bucket having shoulders and coupling extension at rear, links reversibly secured upon opposite sides of extension having shoulders adapted to engage those at rear of extension, bolt holes through link shoulders and coupling extension of extension, bolts having T-shaped heads convergent on sides, correspondingly shaped channels in link ends in which bolts are reversibly fitted, and supplemental pins or bolts by which heads are secured.

DEVICE FOR HOLDING CHECKS UPON MINE CARS.—No. 800,781; J. M. Wysor, Mannering, W. Va.

Device for holding checks upon cars comprising, in combination with car, board, strap hinges secured to inner face of car and to which board is connected, one of hinges extending beyond swinging end of board and turned to form eye, rod having angled end engaging eye, and other end bent to form hook, designed to pass through aperture in side wall of car, and adapted to receive and hold check.

PROCESS OF SEPARATING NICKEL FROM MATTES.—No. 800,130; R. H. Aiken, Winthrop Harbor, Ill.

Method of separating nickel from copper-nickel-sulphide mattes which consists in adding to molten matte in converter suitable highly heated flux material, principally silica, subjecting whole to air blast to oxidize nickel and removing nickel-silicate slag formed before blast has materially acted upon copper.

PROCESS OF REDUCING ORES.—No. 801,129; H. Arden, San Francisco, Cal.

Method of reducing finely divided ores which consists in mixing with ores carbonaceous matter, hydrocarbon, and water glass, forming mixture into coherent masses, coking masses, and finally reducing ores.

PROCESS OF PREPARING DUST ORES FOR BLAST FURNACES.—No. 801,143; H. E. Esch, Giessen, Germany.

Process of preparing ore dust of high fusibility for blast furnace which consists in feeding ore by rotating advancing action first through region of gradually increasing heat, and then into region where it is subjected to stream of ignited fuel mixed with easily fusible material, thereby agglomerating it, and finally removing resulting agglomerated masses.

MOLTEN METAL CONDUCTOR FOR CUPOLAS, ETC.—No. 801,453; C. L. Glover, Newcastle, Pa.

In combination with cupola or other furnace or vessel from which molten metal is drawn, upright conducting basin or vessel located to receive continuous outpour of molten metal, and having below top lateral discharge spout or trough, and mounted to turn on central vertical axis for pouring molten metal into different molds or receptacles, and capable of tilting on horizontal axis to raise up end of discharge spout during such turning for interrupting pouring, capacity of conducting vessel being sufficient to hold inflowing molten metal and prevent overflow during periods of interruption of discharging or pouring.

PROCESS FOR THE PRODUCTION OF METALS OF THE ALKALI GROUP BY ELECTROLYSIS.—No. 801,199; E. A. Ashcroft, Weston, via Runcorn, England.

The herein described process of producing sodium, which consists in electrolyzing preliminary electrolyte consisting of fused sodium chloride over cathode of fused lead and thereafter using fused sodium-lead alloy thus produced as anode, providing fused sodium-hydrate electrolyte for alloy of sodium-lead and directly producing sodium by dissolving it from anode by suitable current and depositing sodium at cathode with consuming secondary electrolyte.

APPARATUS FOR ELECTROSTATIC SEPARATION OF SUBSTANCES OF DIVERSE ELECTRIC SUSCEPTIBILITIES.—No. 801,380; C. H. Huff, Brockton, Mass.

In electrostatic separation, combination of repelling electrode, opposite electrode, means to intensify that concentration of lines of force in static field for which shape and proximity of electrodes are responsible, means to feed material to repelling electrode at region thereon of relatively low field intensity, repelling electrode being rotary to transplant material from point of delivery toward opposite electrode and into region of relatively high field intensity and divider to intercept particles of lower grade of conductivity during movement from repelling electrode.

PROCESS FOR TREATING PRECIOUS-METAL-BEARING MATERIALS.—No. 801,470; C. W. Merrill, Lead, S. D.

Improvements in treating precious-metal-bearing material containing reducing agents, with cyanogen bearing solutions consisting in first collecting material in container and after removal of liquid when present there from interstitial spaces, oxidizing all or part of reducing agent by means of oxygen of compressed air brought into contact with material in same container in which subsequent contact with cyanogen bearing solutions is to take place, and subsequently bringing cyanogen bearing solutions into contact with materials in container.

MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

Former Congressman De Vries of California, now U. S. Appraiser, has returned to the East after an extensive Western trip, taking testimony in the cases of protests by different firms regarding the method followed by the United States officials in assay tests to ascertain the amount of lead in ores. In making these assays it is claimed that the percentage of lead in the dry sample taken is unfairly reckoned as the percentage of the whole lot or cargo. The claim is made by lead importers that the governmental method results in a heavier duty under the 1½ cent per pound tariff than were a different course pursued. The last testimony taken was at Kansas City, Mo., and Mr. De Vries will shortly issue a ruling in the case.

According to a recent report of the United States Geological Survey, the output of platinum in the United States increased from 110 ounces in 1903, valued at $2080, to 200 ounces, valued at $4160, in 1904. The price rose 10% during 1904. The scarcity of platinum, and the consequent rise in price, led to much energy on the part of Eastern smelters of platinum in urging upon the placer miners of the West the advisability of saving platinum in cleaning up the hydraulic mines. The outlook for increased production for 1905 is good, not only on account of the continued high price of platinum, but because of the investigation undertaken by the Geological Survey of the black sands of the Pacific slope and of the increased knowledge thus furnished to the miners in regard to the value of the platinum and to simple means of saving it. The world's total supply of platinum for the year amounted to about 300 kilograms, or 9625 troy ounces, from South America, and 6000 kilograms, or 192,500 troy ounces, from Russia. No production of platinum from Australia was reported. A slight product of both platinum and palladium from the Sudbury copper mines continues to come on the market, but it is not profitable to extract all of the platinum and palladium which these ores could furnish. Increased interest in the occurrence of platinum in hydraulic mines and dredges of the Fraser river is due principally to the fact that the natural alloy of iron and nickel previously found in Josephine county, Or., and in Del Norte county, Cal., has also been found in commercial quantity in the Fraser river at Lillooet. An interesting and new occurrence of platinum in place in Sumatra has been noted by Prof. L. S. Hundeshagen. All the American platinum came from California and Oregon, inasmuch as operations have been suspended in the Rambler copper mine, Wyoming, which furnished some platinum the year before. The imports of platinum into the United States during 1905 showed a decline of more than 8000 ounces, due to European control of the supply. The present prices are the highest that platinum has commanded in recent years.

ALASKA.

Judge Wickersham has delivered a mining decision that has wide application and settled the question as to what constitutes a discovery of mineral under the location laws. It was a four-sided fight for mining ground on Cripple creek at the mouth of Esther creek. It is a continuation, in a sense, of the Sturtevant case. In this the contention is between two groups, as well as against the individual locator — the Sturtevant case being a group against an individual. Here the groups overlap each other. The ground was first taken up as separate mining claims. Then came a group party and located the same ground, and another group party located adjoining ground, which overlapped this ground. Sturtevant was interested in No. 11, Esther creek, and his claim was included in the original group, but he was awarded the decision. The judge, in dismissing the case, said that he had lately come into possession of a ruling from the Supreme Court and this, together with the fact that he had become better acquainted with the conditions, made him feel disposed to modify some of the points laid down in former decisions. The principal interest is the fact that he indicates that one discovery for eight claims will no longer serve—there must be a discovery for every separate claim.

A new smelter is to be constructed on Windy arm, Alaska, according to T. M. Daulton. This smelter proposition is advanced by J. H. Conrad, who has properties on Windy arm. Discoveries made during the past summer make it necessary to have reduction works on the ground. In September a body of copper ore 60 feet in width is said to have been discovered across the arm.

ARIZONA.

Cochise County.

The Tombstone Con. is now sinking below the 800-foot level and no other stations will be cut until the 1000-foot level is struck. It is expected that it will take a year to reach the latter level and handle the water. A winze is being sunk and considerable native silver is being taken from the 400 and 700 levels.

E. G. Kennedy, general manager, and W. G. Barney, mining engineer of the Black Diamond Co., have started work at the mines of the company in the Dragoon mountains, near Tombstone.

Gila County.

Jos. C. Erman, general manager of the Live Oak M. Co., near Globe, has made a contract with the El Paso smelter to ship to that concern 40,000 tons of ore covering a period of eighteen months. The shipments call for not less than fifty tons daily of siliceous and sulphide ores in the proportion of two of the former to one of the latter.

The Arizona & Eastern Con. M. Co. has been formed to develop and operate the Patterson copper claims on Mineral creek, near Globe. E. L. DeLestry is general manager.

Graham County.

The New England Co. of Clifton has raised $100,000 for development purposes and work on an extensive scale is soon to be commenced. General Manager Ayling has gone East. Jacob King, E. M., is in charge of the property.

The output of the Arizona C. Co. for September was 1,972,000 pounds; the output of the Shannon C. Co. was 1,170,000 pounds of copper.

Mohave County.

(Special Correspondence).—The Pyramid mill is running steadily on ore from the Catharine mine. The mill has twelve stamps and is capable of handling 35 tons of ore daily. If the mill handles the ore successfully it will be improved and enlarged. It is operated by W. C. Howard and J. F. Littlefield.

Kingman, Oct 17.

The San Francisco mine, near Kingman, is to be equipped with a compressor and five machine drills. The main shaft is now down 500 feet and the drift from that level is in 425 feet to the north. A contract has been let to drive the drift ahead while the new plant is being put in.——About fifteen men are at work on the Pinkham and Midnight mines at Chloride. On the 230 level of the Pinkham drifts and crosscuts are being run. On the Midnight a crosscut is being driven to the south toward the main vein.——F. H. Griffith, general manager of the Minnesota-Connor mines, near Kingman, reports opening up ore bodies on the 400 and 500 levels. ——All leases on the Billy Bryan mine of the Gold Road group have been declared off and the company will hereafter operate the property.

Pima County.

The Michigan & Arizona Development Co. has decided to exercise its option on 100,000 shares of stock of the Helvetia C. Co., at Helvetia. The holder of the options considers that the development during the past year under the superintendency of F. B. Close justifies the exercise of the option. The general object now is to continue development; 12,000 tons of ore are blocked out.

Pinal County.

The mill of the Desert Queen mine, near Casa Grande, has made its first cleanup. The mill is a twenty-five-ton plant. Work on the mine was commenced the first of the year and it is expected to be a regular producer from now on. Chas. F. Wren is president of the company.

The Florence Mines Co. will put miners to work on the Brooklyn group, in the Ripsey district, near Florence, under the supervision of J. K. McCarthy.——Juan DeArmitt and J. A. Brady have opened a body of copper ore on their Champaign claim in the South Butte district, near Florence.——The Hotchkiss syndicate has ten men developing the Snyder claims, 40 miles from Winkleman station, on the Phœnix & Eastern, in the Banner mining district. N. H. Mellor is in charge of the work.——Superintendent E. R. Stafford of the Arizona Pacific Copper Co., of Woolley, near Florence, reports development work at the mine progressing. The main working shaft is down 40 feet, and a contract has been closed with Robert Pierce for continuing the shaft to the 550-foot level. It is the intention of the company to sink this shaft to the 1000-foot level as rapidly as possible.——James Crowley, who has a lease on the Vekol mine and mill, near Florence, has completed a profitable run.

Yavapai County.

(Special Correspondence).—The Douglas-Lacy mill, recently leased by Fennell & Davis, has resumed operations. Foreman Knight and six men are handling thirty tons daily of high-grade ore from the Gladstone mine, near McCabe, and expect to increase to sixty tons soon. The Gladstone mine is being developed under lease by C. G. Fennell. Eighty men are employed in and about the mine. A new electric dynamo is being placed on the 800, which will furnish power for the hoist to be used in the sinking of the main shaft to the 1000-foot level. The hoist on the surface has reached its capacity. By this arrangement the ore will be raised to a bin on the 800, from whence it will be raised by the other hoists to the surface.——The White G. M. Co., owning properties near Martinez, is putting up a 40-stamp mill, 13 miles from Wickenburg. Construction has stopped temporarily. The building for the mill is completed. In the meantime operations in the mine are progressing satisfactorily. The main tunnel is now in 585 feet, having gained a vertical depth of 600 feet. The tunnel runs alongside the ledge, which is crosscut occasionally. The winze or shaft is 80 feet below the tunnel, and it is 116 feet to the surface, making the total depth of the shaft 196 feet. From the tunnel to the surface the shaft has been timbered, and timbering from the tunnel down is in progress. A 12 H. P. gasoline hoist for the shaft has been received at the mine, so that the ore can be constantly removed as sinking in the shaft continues.——A strike of rich ore is reported in the R. A. M. mine, owned by G. E. Waddell and C. J. McNulty. The properties are on Little Copper creek, near Prescott.

Prescott, Oct. 16.

The capacity of the Richinbar stamp mill is to be increased and other improvements made that will facilitate the production of the mine on a larger scale. The motive power for the present 66 H. P. plant is furnished by water, but to this is to be added a battery of two 60 H. P. boilers to be operated by steam. One of these will always be in use, the other being for emergency. With the new equipment in place the Richinbar mill will handle 60 tons a day, and it can be increased to 70. There are 30,000 tons of ore blocked out. The new 50-ton cyanide plant is completed.

J. J. Carmichael, superintendent of the Pine Mountain M. Co., at Walker, expects to have his mill in operation Nov. 15. Since Aug. 1 he has sunk the shaft on the Pine Mountain mine from a depth of 520 feet and run a drift from the 500-foot level, where he cut a station and ran a drift 50 feet.

A new wagon road is being built from Turkey to Richenbar. At Richenbar ten stamps are to be added to the mill; there will also be concentrators, and a 100 H. P. steam plant will be put in. The Richenbar cyanide plant is ready to start up. Wm. Theisig of Turkey creek is putting in a 2-stamp mill.

E. Greenwood and E. Campbell have bonded from M. D. C. Putman the Express mine, near Poland.—— M. Canton, of Walker, has his main shaft on the north extension of the Amulet down 75 feet.——It is stated that a quartz mill and cyanide plant are to be placed on the Midnight-Test group, south of Prescott, in Groom Creek district.——The shaft on the Baumann Copper Co.'s Swiss Girl mine, at Dewey, is down about 460 feet.

J. Jackson has started work on the Copper Hill mines, south of Prescott in the Copper Basin district. A hoist is to be put in.——It is proposed to build a wagon road from Crown King to Tip Top. H. J. Newhouse, of Beloit, Wisconsin, E. J. Wager, of Prescott, and A. R. White, Jr., are looking over the route.

CALIFORNIA.

Amador County.

The Fremont M. Co., near Amador City, has built two restraining dams in the gulch leading from the mill to Dry creek to prevent sand from the mill filling up the gulch. ——Groom & Parson have discontinued the canvas plant below the Argonaut mill, near Jackson.

Calaveras County.

The Del Monte mill, near Railroad Flat, is kept running, and an addition of five stamps is being made, giving twelve in all.

Del Norte County.

Ore is being taken from the 200-foot level of the Monumental mine at Monumental.——The Elkhorn Placer M. Co. will start hydraulicking, near Monumental, as soon as there is enough water.

Kern County.

B. Ostick, who has a lease on the Merced mine, in the Stringer district, near Randsburg, is taking out rich ore. ——J. O. Balschweid and Y. Ray have a lease on the Pearl Wedge, in the Stringer district.——E. Shipsey and J. J. London are leasing on the Napoleon, in the Stringer district, and have uncovered a vein of high-grade ore. ——H. Giondoni and C. Taylor are leasing on the Little Butte, in the Stringer district.——Regarding tungsten properties near Randsburg, the Californian states that P. Mertz and M. C. Curran are working on the Opportunity and are taking out some very rich ore that goes as high as 72% tungsten. The ore is being sacked for shipment.——T. McCarthy and C. S. Taylor have received returns from a carload of tungsten ore which they shipped to Germany recently. It netted $8000 after paying freight and all other expenses.——McCarthy, Taylor and Grendoni are crosscutting at the 135-foot level in the La Cross mine to tap the rich body of ore believed to pass into the La Cross from the Sunshine. ——J. J. Osborn & Bro. are sinking a shaft on a fraction claim adjoining the La Cross and Sunshine mines.—— A. E. White, owner of the Sydney mines in the southwestern part of the district, which is known as White's camp, is working four men on the Sydney annex. The shaft is down 200 feet and a drift is being run.

Placer County.

Machine drills and an air compressor are to be put in at the Evening Star mine, near Auburn.

Plumas County.

The Alleghany M. Co.'s tunnel, now in 1300 feet, is being driven to tap the channel at the bottom.

Shasta County.

The Pittsburg & Mount Shasta M. Co., which owns the Little Nellie and Bennington mines, between Keswick and Iron Mountain, intends to develop the Bennington and will drive a 400-foot tunnel on the property at once.

The first furnace of the Mammoth C. Co.'s smelter at Kennet was blown in on October 16. Manager Frederick Lyon has returned from St. Louis, and is superintending the work. No. 3 furnace has been started first, No. 2 next, while No. 1 will be last to start up. The water jackets for No. 2 furnace are on their way. As soon as they arrive they will be put in place and this furnace started. The water jackets and machinery for No. 1 furnace are being made.

The Hiatt mine at Buckeye, near the Quartz Hill mine, is to be opened up by W. S. Haskens and associates of San Francisco.——October 26th has been the day set for the final transfer of the Balaklala mine to the White Knob Co., which now has a smelter at Mackay, Idaho. W. H. Brevort is manager.

Sierra County.

(Special Correspondence).—The gravel claims owned by Truman Clark, on the Middle Fork, were recently examined by T. B. Shepard, David Voss and M. C. Emerson of Nevada City.——C. F. Breed, K. C. Parrish and J. W. Hall of Chicago have finished their preliminary examination of the Comet mine in Jim Crow canyon, near Downieville.——The mines of the Sovereign G. M. Co., near Downieville, are being examined by W. J. Belcher.——R. Phelan is putting in an electric plant at Sierra City to furnish power and light for his properties.

Downieville, Oct. 17.

Siskiyou County.

Superintendent J. H. Tibbitts of the Headwater quartz mine, on Humbug, near Yreka, has started up the sawmill at the mine to secure lumber to build a 5-stamp mill.——The new quartz mill and cyanide plant at the Mono mine, on Punch creek, a tributary of Humbug, west of Yreka, has been completed.——W. A. Chamberlain has put in a large pump at the Black Lead mine, on Greenhorn, near Yreka. The Greenhorn Blue Gravel mine is to be worked by the Yreka Blue Gravel M. Co.

Stanislaus County.

J. T. Quinn of Stockton and J. L. Conrad of Knights Ferry plan to dredge the Stanislaus river for gold between Orange Blossom and Knights Ferry.

Trinity County.

The tunnel which will drain Trinity river for ¾ mile and with the aid of a deflecting dam will lay bare the river bed and enable miners to dig the gold that is supposed to be in the sands, is half completed. The works are at Horseshoe bend, and T. H. Seward, A. W. Lindsay and Henry Anderson have them in charge. The tunnel

when finished will be 430 feet long. In driving the tunnel a great quantity of talc has been cut, necessitating much timbering. Notwithstanding all difficulties, the work is half done.——On New River, 16 miles from Hawkins Bar and 65 miles from Eureka, several promising discoveries have been made this year.——The La Grange hydraulic mine, 4 miles from Weaverville, has made a larger output this year under the management of Pierre Bouery than during any previous season. The last cleanup amounted to $70,000. The water was recently turned off and new flumes are being put in preparatory to next season's work. Unusually low water has retarded mining greatly throughout the summer and fall within the watersheds of the Trinity and Klamath rivers.——The Hupp & McMurray placer, near Weaverville, has had a good run for the season.

The Hunter mine, on New River, has been purchased by Robert Hicks of Junction City and J. P. Hennessey of Tonopah. It is equipped with a 3-stamp mill and was owned by F. J. Ladd.

Tuolumne County.

The Big Creek G. M. Co., which recently purchased the Golden Rock ditch from the Merced G. M. Co., have sent General Manager L. R. Wiley of Bangor, Me., to Groveland and vicinity to superintend the work of putting the property in good condition. Men are cleaning out and repairing the ditches and flumes so as to be in position as soon as possible to supply various mines with water. —— The Harvard mine and 60-stamp mill on Whisky Hill, below Jamestown, was sold at public auction recently for $20,000 to W. R. Payson of San Francisco in behalf of J. E. Carroll of Boston.

COLORADO.

(Special Correspondence).—Oil is being reported from various sections of the State. The oil industry of this State, it would seem, could be made much greater than at present if it was properly handled. The Florence field, in Fremont county, seems to be the only district which is producing to any extent. Boulder field does not improve in activity. A couple of years ago the oil industry in Boulder county was at high tide, but a large majority of the companies operating at that time have retired from business. At Debeque, in Mesa county, several wells have been put down during the past year, but in each case the wells have been lost on account of a heavy flow of water, which the operators were unable to control. Some of the companies in this district have a long lease on certain property and are not operating the property but simply waiting until some of their neighbors develop ground in the district.——The old toll roads in the State are fast becoming the property of the county in which they are located. The last one reported to have gone from private hands to the county is near Silverton.

Denver, Oct. 16.

In an epitome of mining conditions in Colorado forecasting the final summary at the close of the current year, the Denver Post says that all signs indicate a material increase of production in both tonnage and value. The zinc output will be the largest on record, owing to the urgency of buyers and the advanced prices paid. The representatives of big zinc consumers at home and abroad have been urging the operators of mills in districts where that mineral is abundant to make special effort for its recovery; therefore a number of mills that hitherto have given it no attention have added proper devices to meet the demand. There has been marked improvement in Leadville, Cripple Creek, San Juan, San Miguel, Dolores, Summit, Gilpin and Clear Creek through the exposure of great ore bodies and in the facilities for mining and reduction. In Park county the London has come to the fore as one of the richest gold mines in the State. A number of idle properties have been started up and the prospect for better work in that section is very favorable. More mills, air compressors and tramways have been built for Colorado mines this year than in any previous time. Telluride is doing better than ever before and so is La Plata county. By reason of the important work done at Silver Plume, East Argentine and on Seaton mountain, the output of Clear Creek county, large as it has been this year, will be more than doubled next year. The same may be said of San Juan county, because the six or eight big mills now building there will be in action soon after next January. Ouray county is favored by a line of improvements at Red mountain and in various other parts of that extensive mining region that can not fail to produce heavily increased yields in the next twelve months. It is coming into its own again after twelve years of discouraging times. The Camp Bird is earning profits; the Revenue is on a better plane than for the last four years; the Crawford syndicate is pushing two big tunnels. The placer mines about Breckenridge, those in South Park, at Keystone, in San Miguel and on Clear Creek below Golden have all had very satisfactory success the past season.

Boulder County.

(Special Correspondence).—The Myrtle M. Co., A. T. Rautenberg manager, is putting in a 48-foot by 60-inch White-Howell roaster, made by the F. M. Davis Iron Works Co. of Denver. They expect to be operating about Oct. 25. Several other properties are doing considerable development work. The proper method of handling the ore has been a serious drawback to the camp, but the Myrtle people believe they have solved the problem, and if they are successful others will follow their example.

Ward, Oct. 16.

The report on the geology of Boulder district, published by the U. S. Geological Survey, describes a rectangle 16 miles north and south by 9 miles east and west. The city of Boulder is southwest of its center. The chief exploitation for oil has been near the center of the area, from 2 to 4 miles northeast of Boulder. It was necessary to make a careful study of areas at considerable distances from the oil wells, because the wells are located in the broad central portion of the district on the outcrop of the Pierre shales, which are in general so nonresistant and homogeneous that exposures of solid rock are rare. Ground water is found in this area at moderate depths. Within the area mapped granite has not yet been quarried or even studied with reference to its use as building stone. The great mass of the Fountain red rock is not adapted to building purposes. Locally, however, there are near its summit beds of the finest quality of structural stone. The Lyons sandstone is the most abundant rock of economic importance. The flagstone industry has its center at Lyons, 3 miles north of this area. Near Boulder the thickness of the beds is generally greater, and the stone is commonly quarried for building. The brick industry at Boulder is large. The development of oil and gas in the Boulder area began in 1901, though their presence was suspected and rumored as early as 1867. Development has been successful only within a limited area, the center of which is from 3 to 4 miles northeast of the city of Boulder and a little less than 3 miles east of the foothills. About 100 wells from 300 to over 3400 feet in depth have been drilled within 5 miles of the McKenzie and about twenty more are scattered over the area between Fort Collins and Golden. The oil production in 1903 amounted to 39,000 barrels.

Clear Creek County.

H. A. Riedel, acting for the Banner Consolidated Mine Co. of Idaho Springs, has a long-time lease and bond on the Donaldson mine on Trail creek. The Donaldson vein will be reached by the Rockford tunnel, which is owned by the Banner Co., 600 feet ahead of its present breast, and will cut the lode at a depth of 1000 feet below the bottom of the deepest shaft on the Donaldson, which is about 600 feet. The tunnel will drain the upper workings, making them accessible, as well as tapping the ore bodies. Machinery is being put in at the portal of the Rockford tunnel.

W. D. Hoover of Denver, owner of the East Griffith mine on Griffith mountain, near Georgetown, has had tests made to determine the best treatment of the ores and will put in a new mill. The East Griffith during the past year has shipped from 200 to 400 tons of smelting ore monthly. No attempt has been made to handle any of the milling ore and much material is blocked out in the various workings. The shaft is to be sunk 500 feet deeper. Drifts are being run from the 100 and 200-foot levels.——The American Sisters mine, near Georgetown, has made its first shipment under the present operators. The shaft is 265 feet deep, and, according to surveys, connection with the Jo Reynolds tunnel No. 4 will be made soon. Drifts are now being run from the 100, 200 and 250-foot levels by Jarbeau & White. —— Cottingham & Craycroft have taken a contract to sink the shaft on Edgar lode, near Georgetown, 50 feet deeper. This shaft is down 115 feet, and is expected to reach the junction of the Edgar, Rodgers and Junction lodes within the next 35 feet. —— The Maine and Phœnix mines, near Georgetown, are to be developed by the Scotia Mines Co. The property is on Sherman mountain. The incorporators are W. P. Jewell, A. W. Rich and A. C. McCall. —— J. Raymond and J. Molloy, owners of the Pinion and Annex properties on Griffith mountain, near Georgetown, have started development work.

The Loops Mines & Tunnel Co., which owns twenty-five claims on Republican mountain, near Georgetown, has retimbered the mouth of its tunnel and is making good headway in pushing the tunnel ahead. It has cut the Hamburg vein.——Winter supplies have been taken to the mines operated by the Silver Plume M. Co.

Gilpin County.

(Special Correspondence).—The Pozo mine in Nevadaville, owned by W. J. Lewis of Central City, is being operated under lease by A. M. Rucker and associates. About fifteen carloads of ore per month are being taken out. The ore runs as high as 35% zinc by the carload. It also carries gold, silver, lead, copper and iron, and is shipped direct to the Lanyon Zinc Co. in Kansas. The ore is handled principally for the zinc it contains.

Central City, Oct. 16.

Gunnison County.

An electric hoist is being put in at the West Gold Hill mines, near Tin Cup. A crusher and rolls being added to the mill will increase the capacity to 100 tons.

Lake County.

The Norton sampling works and zinc mill, owned by H. H. Norton, in the western part of Leadville, were destroyed by fire October 8, involving a loss of $100,000. There was no insurance. The sampling works were built in 1878 by Eddy & James.

In the Mosquito range section, near Leadville, the Winchell has taken out sixty tons of ore from the 20-foot shaft. The Moffat and New York tunnels are being driven steadily ahead. The London is shipping the usual amount of ore.——On the east side of Fryer hill most of the ore comes from the claims controlled by the Fryer Hills mines, the El Paso, Jimmy Lee, Cora Belle and Bangkok and Silver. Both siliceous and sulphide ores are being hoisted. M. O'Brien and J. Ahern, leasing on the north end of the Chrysolite, are shipping steadily a fair grade of iron.

Routt County.

L. A. Pease, of the Boston-Sierra Madre M. Co. of Three Forks, Snake river, near Hahns Peak, has gone East to arrange for a concentrator on the company's property. The Three Forks mining properties are in Colorado and Wyoming. The concentrates will be shipped from Rawlins, Wyo.——The Elkhorn mine, near Columbine, is being worked. A shaft has been put down 150 feet.——The Slavonia district is on the headwaters of the Middle fork of Elk river, 20 miles northeast of Hahns peak, and extends from the upper edge of Hinman park to Mount Zirkel on the Continental divide, the distance being 12 miles in length by 10 miles in width, with its upper confines closely approaching the Larimer county line.——The Martha Vranesich will be developed this winter by a new tunnel at a lower level to strike the vein at a depth of 350 feet, when a shaft will be put down 50 feet to water level. This shaft is expected to develop copper ore.

Saguache County.

The Rollay M. Co., with E. Y. Burns of Alder as superintendent, has let a contract to J. J. Hand of Cripple Creek for 500 feet of sinking. The company employs twenty-five men.——The Chicago M. & S. Co., with John Wisdom superintendent, is operating a claim on Spring creek, 5 miles south of Alder. It is driving a tunnel to tap a vein that the company has opened by a shaft from which the company has shipped several cars of ore. The big tunnel is in about 900 feet.

San Juan County.

The Frisco Mines & Tunnel Co. has given a contract to Richard Whinnerah for a 5000-foot tunnel, 6x7½ feet in the clear, with waterways and pipe lines, to be run through Houghton mountain, in the Mineral Point and Animas Forks districts, 12 miles north of Silverton. The price to be received by Mr. Whinnerah for the work is $16.50 per running foot. The contractor binds himself to make at least 180 feet of bore per month. A 6-drill air compressor and Ingersoll-Sargeant drills, steam boiler and engine have been put in. On the ground of the Frisco Mines & Tunnel Co. on Houghton mountain there are rich mineral veins which will be cut by the proposed bore. The tunnel when completed will afford easy transportation of the ores of the various veins to the Ouray side of the mountain for treatment at the mill to be built by the company, and ultimately the tunnel will be made use of as a carrier for passengers as well as for the product of other mines.

The management of the Bullion Mountain M. Co. with claims in the Needleton district, south of Silverton, after a summer's work with successful results, have closed the property down for the winter, with the intention of resuming operations in the spring. Several other properties in the district will probably continue work all winter, among them being that of the Aztec G. & C. Co.

H. M. Bennett's lease on the Shenandoah No. 3, on King Solomon mountain, near Silverton, is shipping two carloads per week to the Durango smelter. A hoist has been put in and water which threatened to flood the workings is under control.——Milwaukee capitalists have bought claims near the summit of Galena mountain, between the Ridgeway and the Anti-Periodic groups. As soon as new surveys and plats of the territory are completed, the owners intend to develop them. Work on the group will be continued all winter under the supervision of F. E. Schurman of Silverton.

Summit County.

The Morning Star lode, on Mount Baldy, near Breckenridge, which is being operated by Condon & Shrock, is keeping one team hauling ore to the sampler at Breckenridge.

The new stamp and concentrating mill of the Laurium mine in Illinois gulch, near Breckenridge, has been completed and is running day and night on the crude ore from the large veins recently opened by the 1600-foot tunnel and its branches by Niles & Walker. The mill is said to handle about twenty tons of crude ore per twenty-four hours, and reduces five tons of crude ore that assays $7 per ton into a ton of concentrates. Besides the silver and gold contained in the ore, the concentrate carries sufficient lead and iron sulphides to make it of a desirable grade for smelting. An upraise is being driven at the breast, 1640 feet from the portal of the tunnel, on a 2-foot wide streak of partly oxidized smelting ore.

The Mary Verna and the North American companies, near Breckenridge, both of which were organized and floated by J. E. Parker of Memphis, Tenn., have let a contract for a $12,000 power and drill plant to the J. G. Leyner Engineering Co. of Denver, Colo. The plant is to be driven by water power in the Ten-Mile canyon, near Frisco. The same plant is designed to supply the mines of both companies with light and power.

Teller County.

The shaft at the City of Cripple Creek mine is down 415 feet. A drift has been started north toward the First National. —— Preparations are being made by the Omaha Leasing Co. for putting in a larger hoisting plant on the Dexter. It will be placed behind the plant in use, which is proving inadequte. Ore is being raised from the second and third levels and additions are to be made to the shaft. —— Machinery has been put in by J. Jolly, superintendent for the Beacon Hill Leasing Co., on the Robert H. claim on the west slope of Beacon hill. The plant will be used in continuing the shaft, which is down 70 feet. —— It is proposed to sink the Pharmacist shaft, near Cripple Creek, from the 650 to the 1000-foot level. Marshal Bowers is leasing the property.

An adit being driven into the Blue Bell property of Gold hill, Cripple Creek, by a leasing company, is in 650 feet from the portal.

Engineer D. W. Brunton made his report to the mine owners on the proposed drainage tunnel for the Cripple Creek district on October 14. Brunton's plan is to run the new drainage tunnel from Window in the Rock, on Cripple creek, 3½ miles from the El Paso mine. Should the tunnel be extended to the west side of the camp, or to the Vindicator mine, the extreme length of the tunnel will be nearly 6 miles. The tunnel level, as proposed, will be at an altitude of 7660 feet, or 1130 feet below the present El Paso drainage tunnel. The cost of the new tunnel is estimated at $510,000. Engineer Brunton's report was discussed and a decision deferred to the next meeting, which is subject to call. The Rocky Mountain News deduces that the Window in the Rock plan would give 350 feet greater depth at an additional cost of $80,000 over the Gatch park scheme, or only $228 additional vertical foot of ground drained. The tunnel which Engineer Brunton favors would have an elevation of 7660 feet at its portal, as against an elevation of 8020 feet for the Gatch park plan, or 8160 feet for the Cape Horn location. It would drain to a depth of 1130 feet below the present Cripple Creek drainage tunnel. A depth of 1000 feet would be gained and the cost per vertical foot of depth drained would be only $468, as against $581 for the Gatch park tunnel and $628 for the Cape Horn project. The entire cost of the tunnel would be $510,000. It is figured that the Gatch park scheme would take $430,000 to put it through and the Cape Horn $380,000. It would take 2½ years to construct the Window Rock tunnel. Brunton says that the tunnel should cross the eruptive area from the El Paso to the Vindicator mine. The scheme he favors would make the distance from the portal to the El Paso shaft 17,200. He states it is not necessary to crosscut the entire distance to drain it, although the extra expenditure would be justified by

the combined advantages of draining, ventilation and prospecting. The shortest routes to the productive area are found in the Cripple Creek canyon; that while Wilson creek affords some excellent tunnel sites at 8100 feet, the distance to the Gold Coin shaft would be 17,900 feet, and it would be 20,500 feet before the igneous rock is reached to begin drainage. The same result could be obtained, he says, from Cripple Creek a distance of 5000 feet shorter. Engineer Brunton submitted his report at the meeting of the Cripple Creek mine owners, held at the offices of the Elkton Consolidated M. & M. Co. E. A. Colburn of Denver was chairman and A. E. Carlton of Cripple Creek secretary. No definite action was taken regarding the selection of a plan, but a committee was appointed to have the report printed and distributed to the owners for their personal consideration. This committee is composed of Frank G. Peck, representing the Portland: S. S. Bernard of the El Paso and William Lloyd of the Stratton estate. The report was accepted. Brunton was tendered a vote of thanks for the thoroughness with which he treated the matter, his report being a very exhaustive document. The following figures showing the cost and dimensions of the three projects considered were submitted by Engineer Brunton: Cape Horn tunnel, elevation of portal, 8160 feet. Depth below the Cripple Creek drainage tunnel, 630 feet. Distance to the El Paso shaft, 12,840 feet. Distance to the main water channel, 13,840 feet. Distance from the portal to tunnel shaft, 8840 feet. Depth of tunnel shaft, 650 feet. Length of time to complete tunnel, 1.97 years. Cost $380,000. Depth gained 605 feet. Cost per vertical foot of depth drained, $628. Gatch park tunnel: Elevation of portal, 8020 feet. Depth below Cripple Creek drainage tunnel, 770 feet. Distance to El Paso shaft, 14,550 feet. Distance to main water channels, 15,550 feet. Distance from portal to tunnel shafts, 10,570 feet. Depth of tunnel shaft, 880 feet. Length of time to complete tunnel, 2.1/4 years. Cost $430,000. Depth gained, 740 feet. Cost per vertical foot of depth drained, $581. The Window Rock tunnel: Elevation of portal, 7660 feet. Depth below the Cripple Creek drainage tunnel, 1130 feet. Distance to El Paso shaft, 17,200 feet. Distance to main water channel, 18,200 feet. Distance from portal to tunnel shaft, 12,690 feet. Depth of tunnel shaft, 1140 feet. Length of time to complete tunnel, 2½ years. Cost $510,000. Depth gained, 1090 feet. Cost per vertical foot of depth drained, $468.

Two rich finds of ore have been made in the American Eagles mine, on Bull hill, Cripple Creek. In the first level south of the shaft in the back of an old level, 4 feet of mineral is being broken. The other find was made in the second level, and consists of a flat vein.——A. O. Keener, who has a sublease on the Old Summit mine, on Globe hill, has opened a new ore shoot.——The shaft on the Empire State, of the Isabella Co., is down 1100 feet, and at the depth of 1120 feet sinking will be stopped temporarily to permit of levels being driven. A depth of 400 feet has been reached by the Exposition Mines & Leasing Co. in the South Burns shaft of the Acacia Co., on the east slope of Bull hill, Cripple Creek. As soon as a station is cut, sinking will be resumed. The shaft will be continued to a depth of 600 feet.

IDAHO.

Elmore County.

T. J. Brownfield of Lincoln, Neb., is developing the Mary Glenn and Old Sam properties in the Skeleton Creek mining district. A 500-foot tunnel being driven on the Mary Glenn is in 350 feet. On the Old Sam nearly 500 feet of tunnel work has been completed. One well defined ledge and several good stringers have been cut, and recently another ledge, ranging from 4 feet to 7 feet in width, has been discovered. The Skeleton Creek district is on the South Boise drainage, 14 miles by trail east of Atlanta.

The cyanide plant that has recently been put in the Franklin mine at Pine is in operation. It will be used for the tailings from the mill and also on the old tailings dump that has been accumulating at the mine for some time past.

Shoshone County.

It is reported that the Federal M. & S. Co. has bought the Morning mine of Larson & Greenough at Mullan. They have been under bond for $3,000,000. The Morning mine consists of a large group of claims of which the principal ones are the Morning, Evening, Grouse and You Like. These mines are at present worked through the No. 5 tunnel which taps the various ore bodies at a depth of about 1000 feet. The No. 6 tunnel, which was projected to tap these ledges at a depth of 1000 feet below the No. 5 level, recently cut the You Like vein and opened up big chutes of shipping ore and high grade milling ore. It has 1000 feet yet to run to tap the Morning vein. A shaft has been sunk on the Morning vein from the No. 5 level to a depth of 600 feet. On the 200 and 400-foot levels of this shaft drifts have been run on the ledge. The mine is equipped with a 40-drill compressor plant, a 1000-ton concentrator and a narrow gauge railway from the mill to the mine.

James Bond of Black Bear has leased the Argentine mine, 2½ miles west of Wallace.——It is expected that the Hercules 300-ton concentrator near Burke will be completed and ready for operation by November 1. It will be operated by electric power from Spokane. The power line to the mill has just been completed.——The Monarch concentrator near Wallace has been closed down and will not resume operations until there are better transportation facilities. About 20 men are employed at the mine on development work.

Washington County.

In the Rapid River section, near Iron Springs, the Great Northern Mining, Milling & Development Co. has bought the Pedro No. 1 and Pedro No. 2 from W. L. Doiling and C. S. McMillan.

MICHIGAN.

Houghton County.

It is reported that the Calumet & Hecla Co. has purchased a large interest in the Superior copper mine, south of the Isle Royale and operating on the Baltic lode.

MISSOURI.

Jasper County.

The Joplin News-Herald reports that the Billy M. Co., operating on the Teel land near the old Log Cabin mine at Duenweg, have made a rich strike of lead ore. In sinking the shaft a distance of 18 inches in the ore, 1500 pounds of lead are said to have been taken out. There have been a number of good lead strikes in this locality recently, which was at one time the most famous lead diggings in the district.——Two new strikes of ore are reported this week from the Rob Roy lease, south of Joplin—one by Hendry, Blanchard and associates on a two-lot lease just west of the lease of the Togo M. Co., with good ore at 60 feet; the other by G. M. Keller of Joplin and Webb City associates on a two-lot lease south of the Mike the Duck mine, where silicate was struck at 45 feet. Good zinc was shown by the drill at 63 feet, the silicate not being indicated by the drill.

Newton County.

The Auburn M. Co., composed of Chicago and Joplin parties, have secured leases and fees on 1412 acres of land near Spring City and will at once begin mining operations. The company has a shaft down to a good body of ore at this place; but as the pump drained a large section of the country, the company wished to secure control of it also.

MONTANA.

Beaverhead County.

The Silver Fissure M. Co., which is operating the Polaris mine, 40 miles from Dillon, is preparing to haul its smelter machinery from the railroad to the mine with a traction engine. They are grading the road between Red Rock and the mine. J. J. Cusick of Butte is in charge of the work. The engine will have a hauling capacity of 100,000 pounds, and in addition to hauling in machinery, it will be used afterward for transporting coke from the railroad to the plant and hauling matte from the plant to the road.

Fergus County.

About thirty men are employed by the New Mines Sapphire Co. in the Yogo district, near Lewiston. Charles Gadsden is the superintendent, Wallace Danforth mine foreman, and H. E. Maltby timberman. Two shifts are employed in sluicing and cleanups are made four times a day. A shaft has been sunk 100 feet, from which drifts are run to reach the lead. The rock in which the stones are imbedded is raised from the mine by a steam hoist and dumped in piles from the ore carts. It is then saturated with water and left to decompose, after which it is worked through sluice boxes containing riffles. The gravel is placed in a rocker, which has screens of different sized meshes. After the finest screen has been used the cleanup is placed in sacks or boxes and stored away, to be eventually looked over for the sapphires contained therein. The New Mines sapphires are shipped to London, where they are cut, polished and prepared for market. Work in the mine will be continued all winter and sluicing as long as water can be had.

Granite County.

The Goff concentrator, at Garnet, has recently made a shipment of several tons of concentrates to the smelter at Helena.——Having unwatered the property to the bottom of the 150-foot level, Superintendent Illingworth, who is in charge of the Copper Cliff mines, near Garnet, began stoping in the level, and is taking out some high-grade copper ore.——A new lease has been given on the Nancy Hanks, near Garnet, to Thienes and Lowery. They will sink an incline shaft.——C. D. and D. McPherson, who have a bond and lease on the Daisy claims, between Garnet and Top of Deep, have opened a strong lead in the tunnel which they have been driving.

Lewis and Clarke County.

Manager F. M. Smith, of the East Helena plant of the American S. & R. Co., states that the price of lead paid at this smelter for lead in ores has been over 2 cents per pound for 90% of the lead contents. This price is equivalent to a quotation of $3.50 per cwt., less 1½ cent per pound for 90% of the lead contents. Beginning with Monday, October 9, they will pay for lead in ores on the following basis, when the lead is 5% or over: For 90% of the lead contents 90% of the average sales price in New York for common desilverized domestic lead in 50-ton lots, as made by the American S. & R. Co., during the week preceding date of settlement of the lot in question, less 1½ cent per pound, so long as such selling price shall be $4 per cwt. or over. Should such price exceed $4 per cwt., then the price to be paid in settlement would be 90% of $4, less 1½ cent. For example: The selling price of domestic lead in New York is $4.85 per cwt.; 90% of $4 equals $3.60; plus one-half the difference over $4 (42½ cents) equals $4.42½ per cwt.; less 1½ cent per pound equals $2.52½ per cwt. Therefore, instead of paying $2 per cwt. or 2 cents per pound for lead as heretofore, they will pay $2.52½ so long as lead is selling at $4.85 in New York.

Missoula County.

H. J. Rossi and H. J. Read of Wallace has bought the Monitor mine, and will proceed with active work with a large force. E. P. Spalding, manager of the Monarch mine at Murray, will act as consulting engineer. The Monitor is a copper-gold mine, near Saltese, Mont.

Silver Bow County.

The blast furnace of the Pittsburg & Montana Copper Co., with which the company has been making matte since the old blower gave out, is in operation again. It had been closed down a few days to permit of some changes in the manner of getting rid of the slag. In the first place the company had a centrifugal arrangement for carrying the slag outside of the building, but it gave out, and Manager Baggaley decided to install a system like that in use in other smelters.

The plant of the Montana Zinc Co., which is the old 60-stamp mill of the Alice Co. in Walkerville, has been started up again. The mill was closed down recently because of an inadequate water supply. A pipe line has been put in near the Lexington mine, where it is connected with the hill system of the Butte Water Co. to the mill. The company has on hand about 1000 tons of ore from the Lexington mine on which to resume operations. The company expects to run between 80 and 100 tons per day through the mill. The zinc saved from this product aggregates 45% or 50% in addition to which there is some iron and lead, and also some gold and silver in the zinc. The company is figuring on adding machinery that will make the total zinc product 80% instead of 50.

NEVADA.

Esmeralda County.

The Goldfield Custom Mill Co. has been incorporated under the laws of the State of Nevada to build a 20-stamp mill at Gold Center. M. G. Rhodes is president and H. H. Hubbard secretary.

Lincoln County.

Sinking has been resumed at the Pompeii mine, near Searchlight. The mine will be opened up by drifts, crosscuts and upraises, and if the showing to the 600-foot depth is as satisfactory as indicated in the present workings a double compartment shaft will be sunk west of the present gallows frame. This will be used as the main shaft of the mine, the present shaft being used for air.——At the Searchlight M. & M. Co.'s property sinking has been resumed. The water supply is steadily increasing and is now of sufficient volume to keep the mill running continuously. The new pump is handling the flow satisfactorily.——W. R. Gosewisch, president of the New Era M. Co., will sink 200 feet on a new discovery and then drift north towards the main shaft, on the same level, till the two connect. Pumping machinery is to be put in.——E. J. Roberts, manager of the Eldorado-Nevada M. & M. Co., operating the Silver Legion mine at Knob Hill, has started development work.——The new 500-foot working shaft in the Rand ledge has been started by the Black Hawk M. Co. of Eldorado Canyon.

Lyon County.

Ely & McSorley intend to put in a 100-stamp mill and cyanide plant at the Hulley Logan mine, near Como.——The purchasers of the Haywood mine, near Silver City, will also put in a large milling plant.

Nye County.

The Four Ace M. Co. has started a shaft near the base of the south end of Montgomery mountain, near Bullfrog. T. Kilker is superintendent and E. W. Griffith is manager.——The Big Bullfrog double compartment shaft is down 110 feet. A. L. Fontana is superintendent.

NEW MEXICO.

Grant County.

Ground is being graded for the extension to be made to the 200-ton concentrator of the Burro Mountain Copper Co. at Leopold. Twelve additional Wilfley tables and Frue vanners will be put in.

The North American Co. is sinking on the Cobre Negro property, near Lordsburg. The work is being done on the main shaft and is under the supervision of W. E. Hockie.——The Morning Star Co. has decided to sink a development shaft on the Atlantic mine, near Lordsburg. A depth of 800 feet is the intention.

Ground is being graded for the extension to be made to the 200-ton concentrator of the Burro Mountain Copper Co. at Leopold.——Metcalf & Mungaul, working a silver-lead property at Camp Fleming, have netted 191 ounces of silver and 21% lead, or $206.77, from a test shipment of 5300 pounds to the smelter at El Paso.——At Fierro the Hermosa Copper Co. has added twenty-five men to its force; the Phelps-Dodge Co. is employing twenty-five men on the Hanover dump and in the Hanover mine.——The Colorado Fuel & Iron Co. has employed 100 laborers from Mexico in its mines at Union hill and is increasing this force.

OREGON.

Baker County.

Manager E. I. Field of the United Elkhorn mine, near Baker City, says that a drift is being extended on the 400 level of the shaft workings. This work is opening the same shoot that has been explored on the 300, 200 and 100 levels. On the No. 3 level the manager says that he is breaking three sets in width, as the shoot has widened at that depth and the grade of ore is excellent. The milling plant continues to deliver about fifteen tons of concentrates daily at Baker City for the Sumpter smelter. The crosscut which is to open the Baisley vein system at a depth of 1200 feet is being driven.—— A 3-drill compressor is being placed on the Ben Pierce property, Little Salmon district, near Greenhorn. A crosscut is to be driven to open the vein at a depth of 500 feet. O. E. Connors and O. Binkley have an option on this property and expect to work it steadily.——H. H. Ames, one of the owners of the Morning mine, near Tipton, says that the crosscut of the Morning mine may be opening the Fairview ore shoot at a depth of 200 feet below upper workings. This crosscut is on the mill level.

The Don Juan 10-stamp mill, near Greenhorn, has been started by Ellis & Ludwig.

Josephine County.

A. Jeldness of Grants Pass has put men to work at the Blue Ledge copper mines at the head of Applegate river. J. F. Reddy of Jacksonville is interested.

UTAH.

Juab County.

The Supreme Court of Utah has decided in favor of the Grand Central M. Co. in its long-pending litigation with the Mammoth M. Co. Both properties are in the Tintic district. The opinion affirms the decision given by Judge Marioneaux in the District Court for Juab county. The action was begun in September, 1899, by the Grand Central M. Co. against the Mammoth M. Co. to recover $300,000 alleged to be due because of the extraction of 6000 tons of ore by defendant from the Silveropolis mining claim, owned by the plaintiff company. The defendant set up a counter claim, alleging that the ore bodies were in a vein which had its apex in U. S. lot No. 38, which is in Mammoth territory. The issues were tried out on the claim to the apex, and in this Judge Marioneaux, in District Court, ruled in favor

of the Grand Central. The case was first tried before Judge Higgins, who ruled in favor of the Grand Central. But a new trial was granted by Judge Marioneaux, with the result stated. Upon the determination of this point rested the action for damages for the extraction of ore. Judge Bartch's opinion enters with great detail into the testimony of the experts on the case, and into mining laws in general. The gist of the opinion is that the case is largely one of evidence, and on this he rules that the weight is in favor of the Grand Central's contention as to the Silveropolis claim, and while the lower court may have erred in some particulars, his decision must be sustained on the main points in question. The decision covers only the question of title to the ground in dispute, which is awarded to the Grand Central Co., the matter of the $300,000 alleged damages for ores claimed to have been extracted from the ground now awarded to the Grand Central having been held in abeyance until the determination of the question of title. There is another and similar action pending in the Federal court, which had been brought there because of the reincorporation of the Grand Central Co. under the laws of another State.

The ore shipments from Tintic district for the week ending October 13 were: Bullion-Beck, 4; Centennial-Eureka, 58; Gemini, 11; Victoria, 3; Grand Central 7; Black Jack, 1; Mammoth, 8; Ajax, 4; Carisa, 4; Swansea, 6; Eagle and Blue Bell, 8; Eureka Hill (lease) 2; Star Consolidated, 2; Uncle Sam Consolidated, 4; total 127. Concentrates: May Day jigs, 22; Uncle Sam mill, 1; total, 23.

Work has been resumed at the Raymond mine, near Eureka.——A 75-ton mill is to be put in at the Godiva mine, at Eureka. J. C. McChrystal is manager.

Salt Lake County.

The Shawmut Consolidated Copper Co., of Bingham, has decided to push development work just as soon as the mine is unwatered. Superintendent F. A. Darrenougue is in charge of the property and has ordered new machinery. The Crown Point shaft, now 230 feet deep, will be sunk to a depth of 800 feet. S. H. Williams of Boston is general manager.——A new hoist is to be put in at the Bingham Mary.

A. Van Patten, president of the New York & Great Western M. & D. Co., has made arrangements to resume work at the Bazouk mine, Bingham.

Tooele County.

The Eastern & Western G. & C. Co., has been formed to operate claims at Ophir. James Quinn, superintendent of the Buckhorn mine, and Mark Lumb are the owners of the ground.

WASHINGTON.

Ferry County.

A tunnel has been started on the Trojan property, on the summit of the northern end of Toulon mountain. According to the surveyor's figures, the length of the new tunnel will be 775 feet in order to reach the ore body, and will give a vertical depth of 450 feet, cutting the ore body 250 feet lower than tunnel No. 2, which cuts the main ledge 400 feet in from its portal.

WYOMING.

Carbon County.

E. K. Hum, general manager of the Ferris-Haggarty mine, tramway and smelter at Encampment, reports that the Ferris-Haggarty mine has closed down for the winter, but will be opened again as soon as the proposed new railroad is completed to Encampment next April. This action was taken because of the great expense of getting coke into the camp and hauling the copper to the railroad. The big reduction works will continue to run until the ore now in the bins has been exhausted.

FOREIGN.

AUSTRALIA.

Victoria.

The regulations for testing the qualifications of mine managers, under the Victorian Mining Act of 1904, have been published. They provide that every candidate for a certificate must produce evidence as follows: For first-class certificates as mining manager, 5 years' practical mining experience, and be 25 years of age; second-class mining manager's certificate, 3 years' practical mining experience, and be 23 years of age; underground foreman's certificate, 2 years' practical mining experience, and be 21 years of age; battery manager's certificate, 1 year in charge of works or under a competent manager, and be 21 years of age; for a certificate as cyanide works manager, 1 year in charge of works or under a competent manager, and be 20 years of age; for certificate as chlorination works manager, 1 year in charge of works or under a competent manager, and be 20 years of age. In addition to this, candidates must either undergo an examination, or produce a certificate of having passed the requisite examinations of any school of mines or institution approved by the board of examiners for mining managers. The standards for examinations are extremely comprehensive, and cover a wide field.

CANADA.

BRITISH COLUMBIA.

Boundary District.

It was recently announced that the directorate of the Dominion Copper Co. have decided to build their smelter on the North Fork river, ½ mile above the Granby smelter. It has been generally thought that the Morrissey creek situation was the favorite, but it has been learned that by building above the Granby smelter no damage by smoke would be done to any fruit farms, which was feared if the other location had been taken. The new plant will have six furnaces to commence with, with one large stack. The entire plant will cost $750,000, and will take a year and a half to complete.

East Kootenay District.

W. F. Collins, of Perry creek, is preparing to work a bar opposite Old Town, and for this purpose is constructing a flume.

Slocan District.

The Canadian Metal Co. has secured control of the Pilot Bay smelter and of the Bluebell mine, and will begin operations as soon as possible. It has been decided to operate the concentrator at Pilot Bay as soon as it can be restored to working order after seven years' idleness. The company now has two plants, the newly constructed one at Frank and the one at Pilot Bay. It is probable that the Frank plant will be reserved for the treatment of silver and lead ores, to which it can easily and readily be adapted, and that the Pilot Bay smelter will treat zinc ores exclusively. Work on the concentrator has been started. The ore of the Bluebell mine, already available, will supply material for operation for a considerable length of time. The company, however, already has control of many other zinc properties of proved extent and value.

Vancouver Island.

(Special Correspondence).—The Tyee Copper Co.'s smelter ran 11 days in September, and treated 1919 tons of Tyee ore, giving a return, after deduction of freight and refining charges, of $35,019.24.

Duncan's Station, B. C., Oct. 16.

West Kootenay District.

At the Silver Cup mine, near Five Mile, development is being pushed by twenty-five men. A flume is being built to supply water power to the compressor.

MEXICO.

Chihuahua.

The shaft of the San Cristobal, near Parral, is being unwatered with the new 150-gallon bucket and work on the 5th level is being pushed both to the north and south.

The Pinos Altos mill, near Chihuahua, will be put in operation just as soon as the cyanide tanks can be placed in position. Ore has been opened up on the eighteenth level.

The State Government has issued new regulations regarding the taxes on ores. Briefly summarized they state that the value of metals shall be the basis of all taxes. Silver and gold in bars or bulk pay 1½% of their value. When gold or silver are brought to the Federal assay office in Chihuahua the payment of taxes shall be made to the State Treasurer; otherwise, to the tax office of the district whence it came. When the exact value of the gold or silver is not known, the owner can make bond or deposit to the satisfaction of the tax collector, together with a manifest of the number of bars, exact weight and approximate value. When gold and silver are taken from the place of production without compliance with the foregoing articles, such violations are punishable, as provided in the Ley de Hacienda. Ores and metals extracted for reduction in and out of the State for transportation will be taxed on the total value, according to the testing works' liquidations. Included in this valuation are all metals which pay charges according to Article 120 of the Law of Hacienda. Owners or managers before shipping will make a manifest of the exact weight and approximate value before the metals or ores will be allowed to be shipped and the tax office guaranteed the tax by bond or deposit. The State Executive will accept igualas for imports on metals when asked for on the following basis: When the value of the metals contained is $50 or over per ton, 1½%; when the value is $40 and less than $50 per ton, 1¾%; when $30 and less than $40 per ton, 1½%; when the values are less than $30 per ton, 1%. Crushed ore and concentrates will be taxed 1% of their metallic value. To procure an iguala it will be necessary to make a bond to the State Treasurer to the value per year of the tax. Having procured a bond, the recipient thereof will make manifestations. The agencies of reduction plants and the offices of metals buying agencies are obliged to make monthly statements to the tax office in the districts in which they are located. These statements must specify where the consignments are made, the value of the metals in dollars, and the names of the owners. For any violation of this rule the ores will not be permitted to be transported.

Durango.

The Guanacevi Tunnel Co. of Guanacevi will put in air drills. This company have placed a new boiler and hoist on a rich gold vein, which they are now developing at a depth of 120 feet. —— The 300-ton mill which is being built near Guanacevi for the treatment of the product from the Soto group will be started Nov. 15.

Jalisco.

The Mexican Premier Syndicate, Ltd., has taken over the Gachupinas mine, in the Hostotipaquillo district, together with the La Cruz del Sur and Saturno mines in the same district, and it is not unlikely that the America mine of D. B. Nichols and W. J. Payne will be acquired. Operations at the Gachupinas mine are being conducted under the management of D. B. Nichols.——B. H. Hammett of Guadalajara, accompanied by G. J. Snook of Akron, Ohio, president of the Castana M. Co., and H. H. Slater of Cleveland, Ohio, are examining their placers in the Pihuamo district. A hydraulic elevator has been put in and operations will be commenced at once. A dam has been built across the Belem river for storage purposes and a pipe line to carry water from the river 2 miles to the placer has been constructed.

Zacatecas.

The work of unwatering the old San Rafael Grande mine, which extends under Zacatecas, is in progress, and water from the old workings is being supplied to the city of Zacatecas under the contract entered into by the Stilwell Co. and the State Government. The contract specified that the mining operations of the company should be exempted from taxation in return for supplying water to the State capital. The company is headed by Arthur E. Stilwell, president of the Kansas City, Mexico & Orient Railroad. It is estimated that it will cost at least $75,000 to unwater the San Rafael Grande. The mine was at one time one of the greatest producers in Mexico, and it is believed that when the mine is cleared of water and sinking operations are commenced below the old workings rich ore will be again found. The mine is being operated in the upper levels, but the ore there is low grade.

NEW ZEALAND.

According to the Mining Journal, the three Smith-Davidsen mills at the Waihi Co.'s 90-stamp mill at Waihi are doing excellent work, and pulverizing beyond expectations. E. G. Banks, the company's metallurgist, reports that in the earlier working the mills were set the task of grinding the whole of the coarse sands passed through a 25-mesh from ninety stamps. Since then the 20-mesh has been adopted, and the management are pleased to discover that the coarser the sand the mills have to deal with the more effectively and finer they crush. One would naturally surmise that the fine sands from a forty mesh would receive a finer grinding than if the mill had to deal with the coarse sand from the twenty mesh. Not so, however; for the mills grind more rapidly and much finer when the sands are coarse. The importance of the above fact lies in its bearing on the future rapid treatment of ores; for by the use of the 20-mesh the duty of the stamps will show an appreciable increase, while the task the tube mills have to perform can be carried out without any increase of speed or extra labor. They are now crushing and treating fully 30% more ore by the aid of the mills, compared with what their 90-stamp mill was dealing with prior to the acquisition of the tube mills. It is now only a matter of time when the company's Union mill of forty stamps at Waihi, and Waikino mill of 200 stamps at Waikino, will be fully equipped with the required number of mills. The Banks vacuum slime process is satisfactory in action.

Personal.

C. W. PURINGTON is at Sunrise, Alaska.

F. G. FARISH is in Montana on professional business.

A. J. BETTLES has returned to Salt Lake City, Utah, from California.

T. A. LISTER has returned from Pennsylvania to Lordsburg, N. M.

J. J. JACKSON is manager Copper Hill M. & S. Co., near Prescott, Ariz.

A. W. TIBBALS has charge of work of Goldfield G. & C. M. Co., near Goldfield, Nev.

WM. TEMBY has been appointed superintendent Sunset M. Co , near Platteville, Wis.

H. H. NICHOLSON, manager Standard Con. Mines Co. at Quartzburg, Or., is in Mexico.

H. C. CUTLER has been appointed superintendent Sandstorm mine at Columbia, Nev.

B. F. HARTLEY, superintendent Three Stars mine, near Auburn, Cal., is on a trip East.

C. T. BROWN has returned to Socorro, N. M., from mine examination at Tres Hermanos.

RICHARD ROUSKELL of Calumet, Mich., has returned from inspecting mines near Globe, Ariz.

PETER DAWE of Hancock, Mich., has been appointed mine inspector for Houghton county, Mich.

W. B. MORRIS has succeeded H. C. Cutler as superintendent North Star mine at Tonopah, Nev.

WILLIAM WILLIAMS of Ironwood, Mich., is superintendent Comanche M. Co., near Silver City, N. M.

F. A. HILL has succeeded G. H. Broome as manager Canadian Coal & Coke Co. at Frank, Alberta, Canada.

W. F. MILLER, manager the United States Tin Co., has begun operations at Corona, Riverside county, Cal.

HOMER WILSON, president Wildman Con. M. Co., has returned to San Francisco, Cal., from New York City.

V. C. HEIKES of the United States Geological Survey is visiting the mining districts of Mohave county, Arizona.

T. J. GALIGER, superintendent Stockton G. M. & M. Co. at Stockton, Tooele county, Utah, has gone East on business.

KARL STAAHLGREN, president Wayne M. Co., has returned to the mines at Granite Falls, Wash., from New York City.

J. H. MCCHRYSTAL, formerly of Salt Lake City, Utah, has opened offices as mining engineer at 333 Pine street, San Francisco, Cal.

Z. A. HARRIS of Cleveland, O., president Twentieth Century M. Co. at Roosevelt, Idaho, has been at Boise, Idaho, on company business.

H. B. LODWEN has assumed the position with the Colorado Iron Works Co., Denver, Colo., made vacant by the resignation of F. S. Cronk.

EDGAR RICKARD, who recently resigned the managership Progresso M. Co., Triunfo, Baja California, is in California, his present address being 21 Fremont St., San Francisco, Cal.

Davidson, Iron Mountain; William Kelley, Vulcan; W. J. Richards, Crystal Falls; J. H. McLean, Ironwood; H. F. Ellard, Ironwood; George B. Morley, Saginaw; E. B. Foos, Bay City.

Latest Market Reports.

SAN FRANCISCO, October 20, 1905.

METALS

SILVER. — Per oz., Troy: London, 28 1/16d (standard ounce, 925 fine); New York, bar silver, 62½c, refined (1000 fine); San Francisco, 62¼c; Mexican dollars, 50c, San Francisco; 47½c, New York.

Bar silver is higher locally, in New York and in London, than for some time past, the quotation at present being 62¼ cents per ounce. Although the advance is small, it means, in most cases, just that much additional profit, as the expense of producing the metal is not in the least increased. While the hope for high-priced silver is a thing of the past, every small advance over 60 cents is gladly welcomed by producers of the metal.

COPPER.—New York: Standard, $16.37½; Lake, $16.37½@16.75; Electrolytic, $16.32½; Casting, $16.00@16.37½. San Francisco: $16.75. Mill copper plates, $17.50; bars, 18@24c. London: £72 10s spot per ton.

Copper shows a firm tone, there being a slight advance over last week's quotations. Those controlling the market have no desire, apparently, to allow the price to go above 17 cents, as it stimulates production in too large a degree, while also offering an inducement to consumers to substitute other metals — iron, aluminum, etc. — for copper.

LEAD.—New York, $5.50; St. Louis, $4.50; San Francisco, $5.00, carload lots; 5¼c 1000 to 4000 lbs.; pipe 7½c, sheet 8, bar 6½c. London: £14 18s 9d ₱ long ton.
